As already mentioned, where it is intended to use the method of the invention for the production of a circuit component regard may be had to that fact in the electrical design of the component. Figure 16 is a cross-section of a transformer designed to be built by the method of this invention. Its windings 61 may be built of superposed spirals, such as are illustrated in Figure 7, all of the same external diameter but decreasing in radial depth from the middle outwards. Primary and secondary windings may be printed together, closely intermingled to eliminate magnetic leakage. Together the superposed imprints form an annulus of roughly triangular cross-section. Alternatively the winding may be wound of wire upon a former of V-section. The core is built from the printed strip 62 shown in Figure 17; it is a slightly tapering strip (the taper is exaggerated in the figure) on which are formed a large number of parallel closely spaced iron lines. This strip is of very thin insulating material. The middle of the strip is reinforced by a narrower tapered strip 63. The composite strip is wound around the winding 61 and as it is wound it is folded about the edges of the reinforcing strip, so that the ends of the iron lines come together in the middle of the core as seen in Figure 16. Its insulation breaks and crumples permitting the iron lines to overlap radially. The ends of the lines are brought into good magnetic contact and so held by the end cheeks 64 and the bolt 65.

The invention is by no means confined to the building of circuit components for radio receivers. The pattern of parallel lines described with reference to Figure 9 is a typical pattern

12

for the production of electrical resistances, for example for all kinds of heaters. The pattern of parallel resistant conductors may be wanted upon some article or fabric to be heated on which it is not convenient to print. In that case the resistant pattern is produced by printing upon a temporary ground, for instance printing upon foil of resistant metal upon a backing of waxy paper, and is transferred to its permanent backing by a subsequent operation. The method of printing and etching and subsequent transfer, for example, might well be used to produce a resistant conductor upon cement or plaster of Paris.

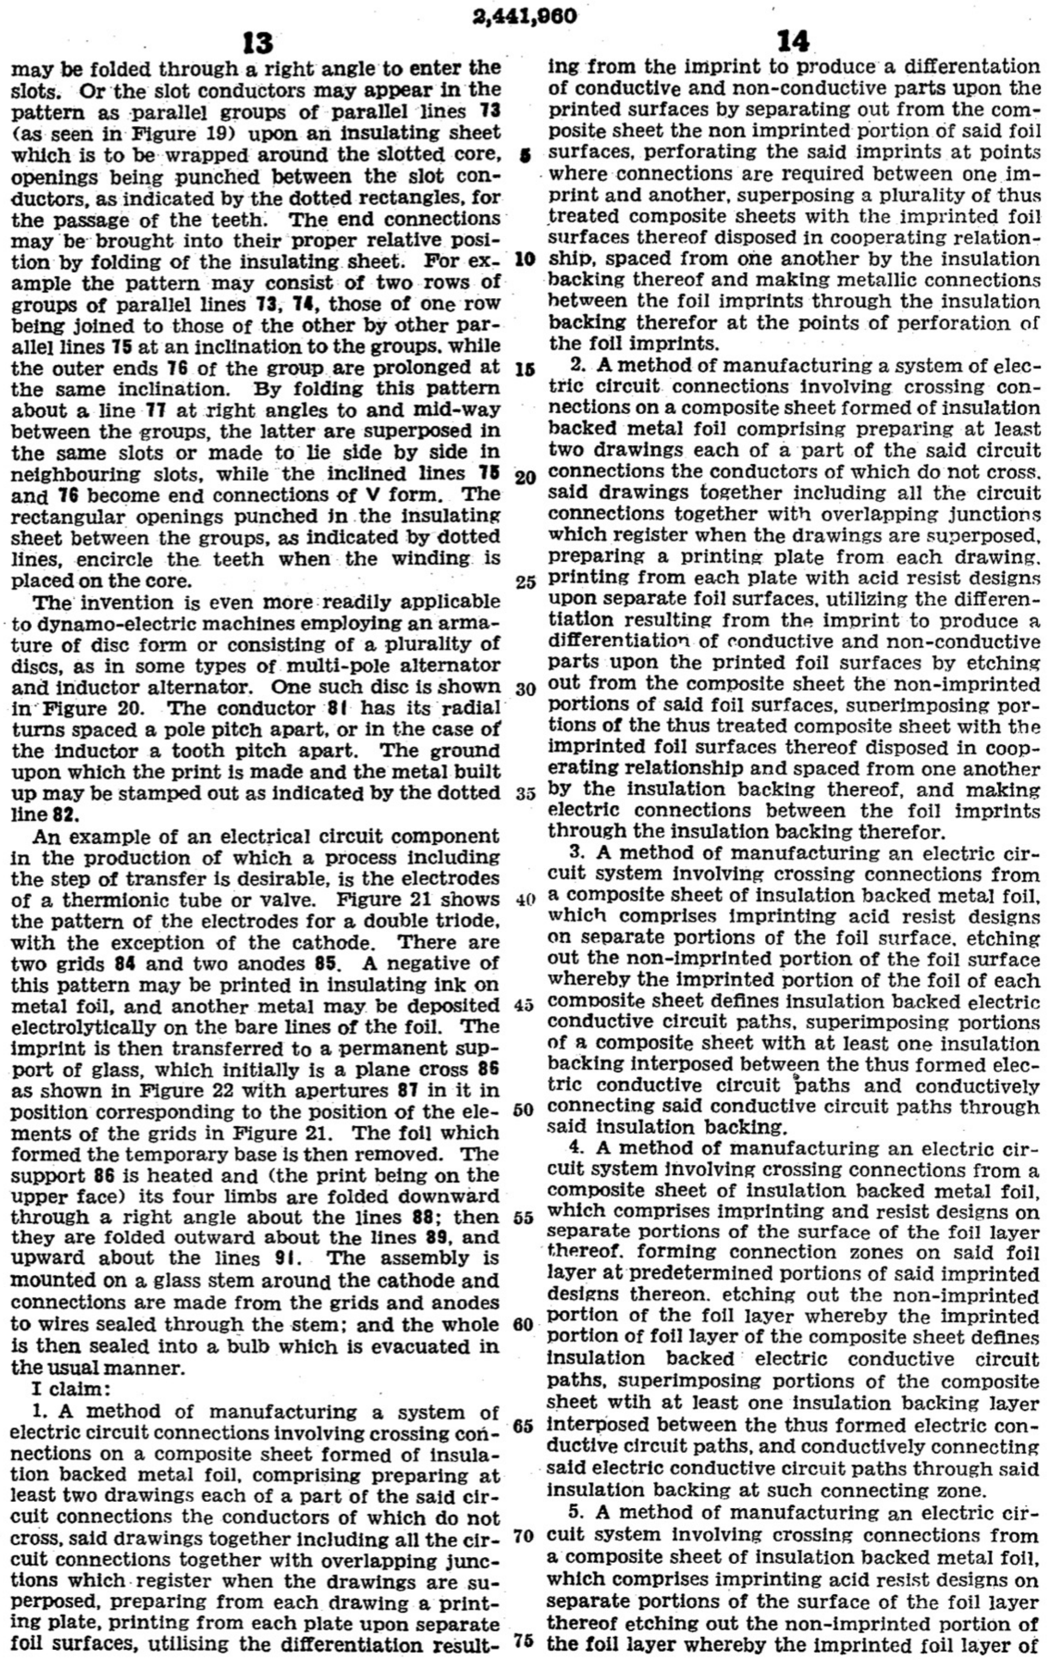
A resistant conductor such as indicated in Figure 9 may be formed upon wall-papers, wall and furniture panels, curtains, and other hangings, upholstery fabrics, floor coverings, clothing and bed-clothing, and the like for the purpose of making electric heaters or rather warmers of them. Such a conductor, though of small thickness, will carry a substantial current because its flat form promotes loss of heat by radiation and conduction. The conductor will be insulated and protected by a covering, for instance of a varnish or plastic on which powdered metal oxide may be dusted to increase radiation; in the case of aluminium the conductor is preferably covered by oxidation for the same reasons.

When used on ordinarily ornamental fabrics such as wall-papers the pattern of Figure 9 may be made to provide or contribute to the ornamentation by a double printing process. There is first produced a pattern of parallel lines of say, aluminium, copper, zinc, iron or nickel. Upon this any ornamental design 53 is printed in an insulating ink. The sheet is then made the cathode in an electrolytic bath by which copper is deposited on the metal lines except where covered by ink. The final product is, as before, a sheet with a pattern of parallel lines of which those parts within the design are of higher resistance than the remainder. Alternatively the over-printed sheet may be anodised to bring about reduction in the cross-section of the unprotected parts.

However, the second pattern may be superposed merely for its appearance without any thought of making the pattern rather than the non-patterned part the source of heat, or vice versa. In this case it may be desired to render the pattern of parallel lines inconspicuous to the eye, by suitable dyeing of the base, or of the oxide-coated or otherwise insulated conductor. For such overprinting a pattern of parallel lines of aluminium may be used with advantage, and the sheet subjected to an anodising process and dyeing process by which effects of some beauty may be produced. By the use of dyes which change colour at a temperature above atmospheric and below that which the conductor, or a part of it, reaches when carrying current, a visual indication may be given when the heat is on.

A class of printed patterns deserving mention is the patterns for winding the toothed cores of dynamo-electric machines. In one form shown in Figure 18 the pattern is mainly a star, in which each ray is a group of parallel conductors 71 representing the conductors of one slot; the inner and if desired the outer ends of the rays are prolonged at an angle to their length to form end connections preferably of the form of involutes of a circle; the insulating material between the groups of slot conductors is removed as indicated by the doubled lines, so that the slot conductors

Figure B.121: Paul Eisler produced printed circuits in 1936 and filed a detailed patent application in 1944.



2,441,960

13

may be folded through a right angle to enter the slots. Or the slot conductors may appear in the pattern as parallel groups of parallel lines **73** (as seen in Figure 19) upon an insulating sheet which is to be wrapped around the slotted core, openings being punched between the slot conductors, as indicated by the dotted rectangles, for the passage of the teeth. The end connections may be brought into their proper relative position by folding of the insulating sheet. For example the pattern may consist of two rows of groups of parallel lines **73**, **74**, those of one row being joined to those of the other by other parallel lines **75** at an inclination to the groups, while the outer ends **76** of the group are prolonged at the same inclination. By folding this pattern about a line **77** at right angles to and mid-way between the groups, the latter are superposed in the same slots or made to lie side by side in neighbouring slots, while the inclined lines **75** and **76** become end connections of V form. The rectangular openings punched in the insulating sheet between the groups, as indicated by dotted lines, encircle the teeth when the winding is placed on the core.

The invention is even more readily applicable to dynamo-electric machines employing an armature of disc form or consisting of a plurality of discs, as in some types of multi-pole alternator and inductor alternator. One such disc is shown in Figure 20. The conductor **81** has its radial turns spaced a pole pitch apart, or in the case of the inductor a tooth pitch apart. The ground upon which the print is made and the metal built up may be stamped out as indicated by the dotted line **82**.

An example of an electrical circuit component in the production of which a process including the step of transfer is desirable, is the electrodes of a thermionic tube or valve. Figure 21 shows the pattern of the electrodes for a double triode, with the exception of the cathode. There are two grids **84** and two anodes **85**. A negative of this pattern may be printed in insulating ink on metal foil, and another metal may be deposited electrolytically on the bare lines of the foil. The imprint is then transferred to a permanent support of glass, which initially is a plane cross **86** as shown in Figure 22 with apertures **87** in it in position corresponding to the position of the elements of the grids in Figure 21. The foil which formed the temporary base is then removed. The support **86** is heated and (the print being on the upper face) its four limbs are folded downward through a right angle about the lines **88**; then they are folded outward about the lines **89**, and upward about the lines **91**. The assembly is mounted on a glass stem around the cathode and connections are made from the grids and anodes to wires sealed through the stem; and the whole is then sealed into a bulb which is evacuated in the usual manner.

I claim:

1. A method of manufacturing a system of electric circuit connections involving crossing connections on a composite sheet formed of insulation backed metal foil, comprising preparing at least two drawings each of a part of the said circuit connections the conductors of which do not cross, said drawings together including all the circuit connections together with overlapping junctions which register when the drawings are superposed, preparing from each drawing a printing plate, printing from each plate upon separate foil surfaces, utilising the differentiation resulting from the imprint to produce a differentation of conductive and non-conductive parts upon the printed surfaces by separating out from the composite sheet the non imprinted portion of said foil surfaces, perforating the said imprints at points where connections are required between one imprint and another, superposing a plurality of thus treated composite sheets with the imprinted foil surfaces thereof disposed in cooperating relationship, spaced from one another by the insulation backing thereof and making metallic connections between the foil imprints through the insulation backing therefor at the points of perforation of the foil imprints.

14

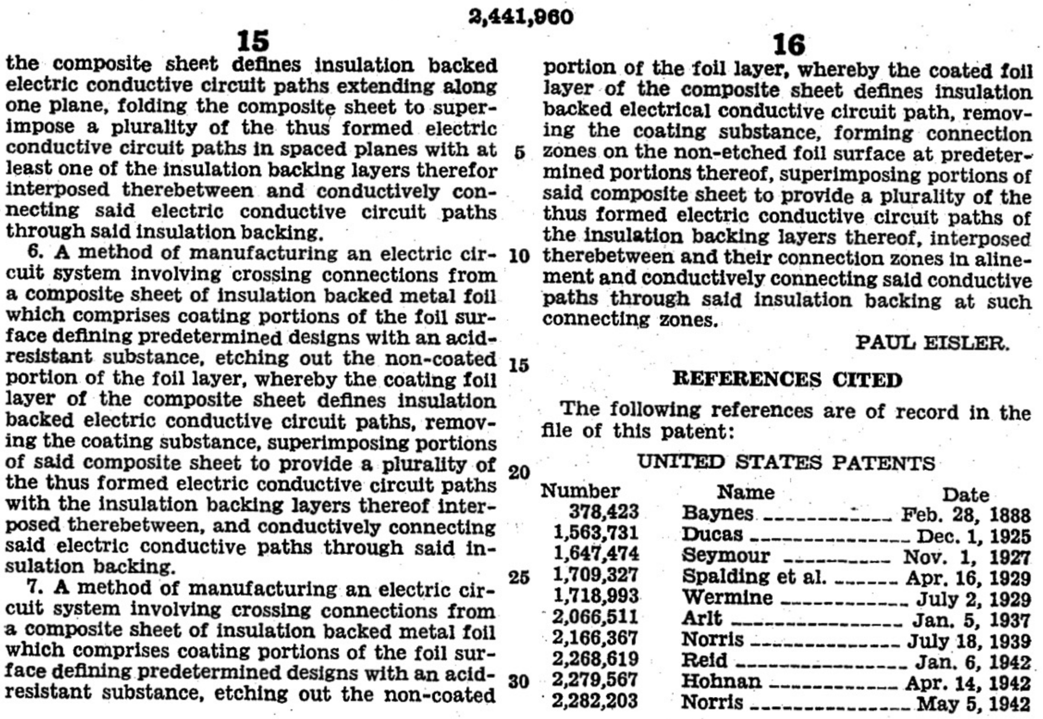
2. A method of manufacturing a system of electric circuit connections involving crossing connections on a composite sheet formed of insulation backed metal foil comprising preparing at least two drawings each of a part of the said circuit connections the conductors of which do not cross, said drawings together including all the circuit connections together with overlapping junctions which register when the drawings are superposed, preparing a printing plate from each drawing, printing from each plate with acid resist designs upon separate foil surfaces, utilizing the differentiation resulting from the imprint to produce a differentiation of conductive and non-conductive parts upon the printed foil surfaces by etching out from the composite sheet the non-imprinted portions of said foil surfaces, superimposing portions of the thus treated composite sheet with the imprinted foil surfaces thereof disposed in cooperating relationship and spaced from one another by the insulation backing thereof, and making electric connections between the foil imprints through the insulation backing therefor.

3. A method of manufacturing an electric circuit system involving crossing connections from a composite sheet of insulation backed metal foil, which comprises imprinting acid resist designs on separate portions of the foil surface, etching out the non-imprinted portion of the foil surface whereby the imprinted portion of the foil of each composite sheet defines insulation backed electric conductive circuit paths, superimposing portions of a composite sheet with at least one insulation backing interposed between the thus formed electric conductive circuit paths and conductively connecting said conductive circuit paths through said insulation backing.

4. A method of manufacturing an electric circuit system involving crossing connections from a composite sheet of insulation backed metal foil, which comprises imprinting and resist designs on separate portions of the surface of the foil layer thereof, forming connection zones on said foil layer at predetermined portions of said imprinted designs thereon, etching out the non-imprinted portion of the foil layer whereby the imprinted portion of foil layer of the composite sheet defines insulation backed electric conductive circuit paths, superimposing portions of the composite sheet wtih at least one insulation backing layer interposed between the thus formed electric conductive circuit paths, and conductively connecting said electric conductive circuit paths through said insulation backing at such connecting zone.

5. A method of manufacturing an electric circuit system involving crossing connections from a composite sheet of insulation backed metal foil, which comprises imprinting acid resist designs on separate portions of the surface of the foil layer thereof etching out the non-imprinted portion of the foil layer whereby the imprinted foil layer of

Figure B.122: Paul Eisler produced printed circuits in 1936 and filed a detailed patent application in 1944.



the composite sheet defines insulation backed electric conductive circuit paths extending along one plane, folding the composite sheet to superimpose a plurality of the thus formed electric conductive circuit paths in spaced planes with at least one of the insulation backing layers therefor interposed therebetween and conductively connecting said electric conductive circuit paths through said insulation backing.

6. A method of manufacturing an electric circuit system involving crossing connections from a composite sheet of insulation backed metal foil which comprises coating portions of the foil surface defining predetermined designs with an acid-resistant substance, etching out the non-coated portion of the foil layer, whereby the coating foil layer of the composite sheet defines insulation backed electric conductive circuit paths, removing the coating substance, superimposing portions of said composite sheet to provide a plurality of the thus formed electric conductive circuit paths with the insulation backing layers thereof interposed therebetween, and conductively connecting said electric conductive paths through said insulation backing.

7. A method of manufacturing an electric circuit system involving crossing connections from a composite sheet of insulation backed metal foil which comprises coating portions of the foil surface defining predetermined designs with an acid-resistant substance, etching out the non-coated portion of the foil layer, whereby the coated foil layer of the composite sheet defines insulation backed electrical conductive circuit path, removing the coating substance, forming connection zones on the non-etched foil surface at predetermined portions thereof, superimposing portions of said composite sheet to provide a plurality of the thus formed electric conductive circuit paths of the insulation backing layers thereof, interposed therebetween and their connection zones in alinement and conductively connecting said conductive paths through said insulation backing at such connecting zones.

Technologica[illegible] industrial organization that permitted the German war machine to maintain high output, despite difficulties in communications and transportation and shortages in skilled manpower, offers invaluable clues for improving the mass production methods of American manufacturers, according to Dr. Todos M. Odarenko, of the Office of Technical Services, Department of Commerce.

Dr. Odarenko recently returned from Germany where he headed the overseas Electronics and Communications Unit of OTS Technical Industrial Intelligence Division. He was on leave of absence from his position as a member of the Technical Staff of the International Telephone and Telegraph Company, New York City.

"American industry now has the unparalleled opportunity of mastering German production techniques that has already saved an inestimable amount of time and money in independent research and experimentation and will save more as the exploitation of German practices and their utilization is completed", Dr. Odarenko declared. "American businessmen and manufacturers should send investigators to Germany at once, for as German plants reconvert to peacetime operations, they will become less readily accessible for study by American investigators."

Though the fundamental ideas of many developments in German production methods and processes were not exactly unknown to American engineers, their successful application on a wide scale was novel, Dr. Odarenko stated. Consequently, obtaining exhaustive knowledge of the "know-how" for similar wide scale use in America is of paramount importance, according to Dr. Odarenko.

In Communication and Electronic industries the Germans speeded production by reducing the amount of piece-meal assembly work, by a large scale use of forgings, castings, molds and pre-assembled component units, Dr. Odarenko said. For example, they invented an ingenious machine that casts in one operation complicated radio or radar chassis with precision of such nature that no, or but little, further machining is necessary.

"Previously, the chassis were stamped out of sheet metal, and the partitions and supports -- angle arms and the like -- for each of the many components used in a radio or radar set had to be bolted, screwed or welded separately to the chassis", Dr. Odarenko explained. "The casting machine combines all these separate operations into one, conserving time and labor."

A similar German development for expediting the mounting of electronic assemblies was the wide use of ceramic insulating plates with printed or stamped painted or sprayed, and baked in, electrical connections. These reduced or completely eliminated the need for the conventional, laborious wiring, Dr. Odarenko said.

The need for thoroughly studying German technique is also an essential requirement for successfully manufacturing in the States of many ingenious devices and of useful materials developed or invented in Germany in recent years, Dr. Odarenko declared. Frequently, attempts at manufacture proved that careful reading of the available documents describing the composition of the material and the machinery for its production as well as detailed physical examination of both the material and the machinery revealed insufficient information.

For example, Dr. Odarenko said, American manufacturers ran into difficulty, when they attempted to reproduce the German process for converting powdered polystyrene into a tough plastic film called "styroflex". The film has excellent dielectric and mechanical properties, and the Germans successfully used it in high-frequency cables, in submarine cables and as a substitute for mica sheets in high-precision, electrical fixed condensers. The American manufacturers, however, found that the plastic film they produced lacked the uniformity of thickness, the stability and the flexibility of the German-made product. Thus, quite recently, a special team of experts had to be sent from the States to obtain

additional detail information from the North German Submarine Cable plant of Nordenham, the company that perfected the conversion process.

"A little time spent in on-the-spot investigation in Germany before going into production", Dr. Odarenko pointed out, "will more than repay a manufacturer for the expense of sending an investigator to Germany."

Dr. Odaranko spent 4 months in Germany this year and about 6 months last year for the Electronics and Communications Unit of OTS' Technical Industrial Intelligence Division. From 1928 to 1943, he worked as a member of the Technical Staff for the Bell Telephone Laboratories, and prior to joining the staff of the International Telephone and Telegraph Company, he served as a consultant and advisor for the Bureau of Ships of the U.S. Navy and the Radar Division of the War Production Board.

Manufacturers interested in sending investigators to Germany should communicate with John C. Green, Director, Office of Technical Services, Department of Commerce, Washington 25, D. C.

Dear friend Webb:

Although I am out of my Washington job people still ask me questions about what information is available in your department. Lately I have had an inquiry from our friend Espenschied about the recent art of painting or stamping circuit elements and wiring on plates of plastic. We understand that the Bureau of Standards people have been working on this. The question is, did this originate with the Germans, and if so are there any reports on it? I don't want you to go making searches through the indexes and elsewhere that we might do ourselves, but I thought I would first ask if you knew of any such reports, in which case we might be saved some time and effort.

My new work in our Patent Department is very interesting and quite agreeable. But I miss my trips to your city and our pleasant contacts. I hope your work is progressing satisfactorily. But what about the big new venture that was talked of?

With best wishes to you and your staff,

Julian Blanchard

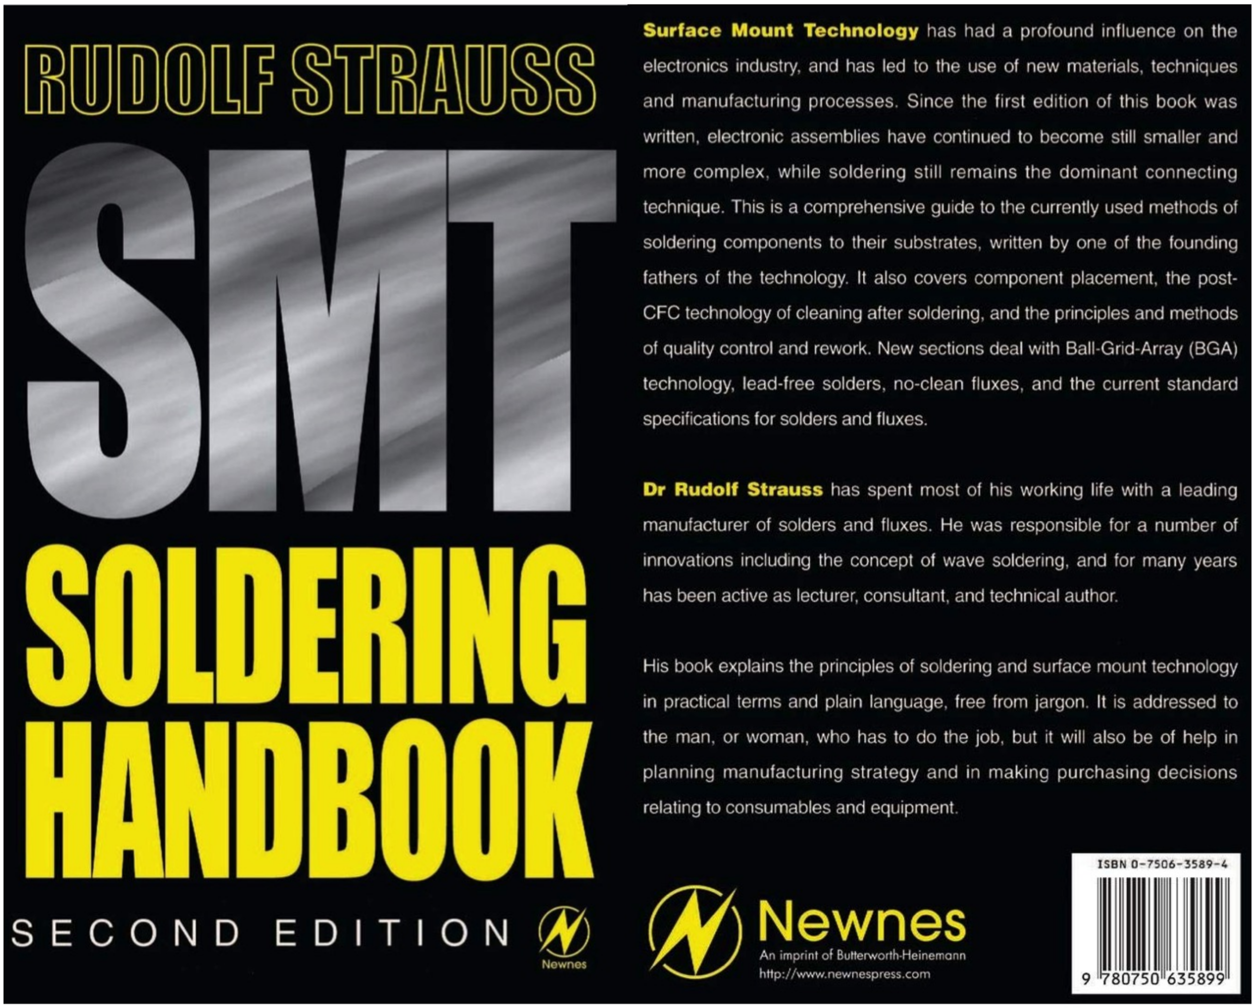
Rudolf Strauss (1913–2001) invented wave soldering for printed circuits, or surface mount technology (1951–1955)



RUDOLF STRAUSS

SMT SOLDERING HANDBOOK

SECOND EDITION

Newnes

Surface Mount Technology has had a profound influence on the electronics industry, and has led to the use of new materials, techniques and manufacturing processes. Since the first edition of this book was written, electronic assemblies have continued to become still smaller and more complex, while soldering still remains the dominant connecting technique. This is a comprehensive guide to the currently used methods of soldering components to their substrates, written by one of the founding fathers of the technology. It also covers component placement, the post-CFC technology of cleaning after soldering, and the principles and methods of quality control and rework. New sections deal with Ball-Grid-Array (BGA) technology, lead-free solders, no-clean fluxes, and the current standard specifications for solders and fluxes.

Dr Rudolf Strauss has spent most of his working life with a leading manufacturer of solders and fluxes. He was responsible for a number of innovations including the concept of wave soldering, and for many years has been active as lecturer, consultant, and technical author.

His book explains the principles of soldering and surface mount technology in practical terms and plain language, free from jargon. It is addressed to the man, or woman, who has to do the job, but it will also be of help in planning manufacturing strategy and in making purchasing decisions relating to consumables and equipment.

APPARATUS FOR SOLDERING

Allan Francis Charles Barnes, London, Victor Bernard Elliott, Wallington, and Rudolf Siegfried Strauss, London, England, assignors to Fry's Metal Foundries Limited, London, England
Filed Oct. 9, 1956, Ser. No. 614,873
Claims priority, application Great Britain Oct. 14, 1955
3 Claims. (Cl. 113—126)

Components, such as resistors, capacitors, valve sockets and the like are normally assembled on the rear surface of the insulating panel of a printed circuit by inserting pins on the components through suitably placed holes in the circuit panel. It is then necessary to solder the pins to the metal of the printed pattern to secure effective electrical connection of the components to the printed circuit.

The existing practice is to coat the front surface of the panel, i.e. the surface on which the circuit is printed, with a soldering flux, preferably a rosin based flux, and then to dip the flux coated front surface of the panel into a bath of molten solder. This procedure, however, has the disadvantage that the flux may accumulate around the joints to an extent sufficient to deny access to the solder, with the result that an inadequate electrical connection is produced. Another disadvantage is that the surface of the bath is covered with a film of oxide which may prejudice effective soldering. This oxide film has to be removed each time before a panel is dipped which complicates the dipping procedure and in addition, a certain amount of solder is wasted.

The invention provides a method of soldering components to the panel of a printed circuit which consists in effecting relative movement between the panel and a stream of molten solder directed against the flux-coated surface of the panel. The solder will, in this case, be effective to wash out any flux which may have penetrated into the holes in the panel and so ensure effective electrical connection of the pins to the circuit. This method of soldering in effect provides an angled contact between the entire surface to be soldered and the surface of the solder. This permits the flux to be displaced readily by the molten solder, giving the latter complete and unhindered access to the joints to be soldered. In addition, since the panel is in contact with a moving stream of solder, the chilling effect of the panel is negligible, the rate of heat transfer is greatly improved and consequently any part of the panel need be in contact with the molten solder for less time than in the case of flat dipping to produce a satisfactory electrical joint. Another advantage is that since the stream of solder is derived from below the free surface of the bath it is free from oxides or other contaminants.

Preferably the stream of solder is directed vertically upwards against the flux coated front surface of the panel, although it may be directed at any other convenient angle to the surface. Most conveniently, the solder is ejected upwardly against the panel through a rectangular nozzle of a length exceeding the width of the panel, and the panel is moved relatively to the jet until its entire surface has received an application of solder.

The invention includes apparatus for soldering components to the panel of a printed circuit comprising a tank to contain molten solder, a nozzle having a narrow, elongated rectangular mouth disposed horizontally and above the normal level of solder in the tank, a pipe in the tank communicating at one end with the lower end of the nozzle and open at the other end to the solder in the tank, a pump in the pipe which is operative to discharge solder upwardly from the mouth of the nozzle in a wave having a level crest, and horizontal rails adjacent the narrow ends of the mouth of the nozzle for supporting the panel and permitting it to be traversed over the nozzle with its undersurface in contact with the crest of the wave of solder.

2

One specific apparatus for carrying the invention into effect will now be described in detail, by way of example, with reference to the accompanying diagrammatic drawing, in which:

FIG. 1 is a vertical section through the apparatus,

FIG. 2 is a section on the line II—II in FIG. 1,

FIG. 3 is a section on a larger scale on the line III—III in FIG. 1, and

FIG. 4 is a perspective view of the nozzle partly in section.

The printed circuit to be soldered is made in any conventional way, e.g. by applying a coating of copper to a panel of insulating material, applying a pattern of acid-resistant ink to the metal coating, etching away the metal unprotected by the ink and removing the ink. Holes are then made in the panel at the points where components are to be connected to it. The components are then assembled on the back of the panel by pushing their contact pins through the holes and flux is applied, e.g. by spraying, to the front surface of the panel.

In the drawing, the panel is indicated at **10**, certain of the components on the panel at **11** and the downwardly projecting pins at **12**. The panel **10** is supported with its flux coated side downwards by a carriage **13**, having wheels **14** by which it can be traversed along horizontal rails **15**.

The rails **15** are located above a tank **16** containing molten solder **17** heated either by an immersion heater or by an external gas heater. Supported in the tank by suitable brackets, not shown, is a pipe **18**, open at one end to the solder in the tank and connected at the other end to a nozzle **19**. The nozzle has a narrow, elongated rectangular mouth **20** extending horizontally above the level of the solder in the tank and with its longer dimension extending transversely to the rails **15**.

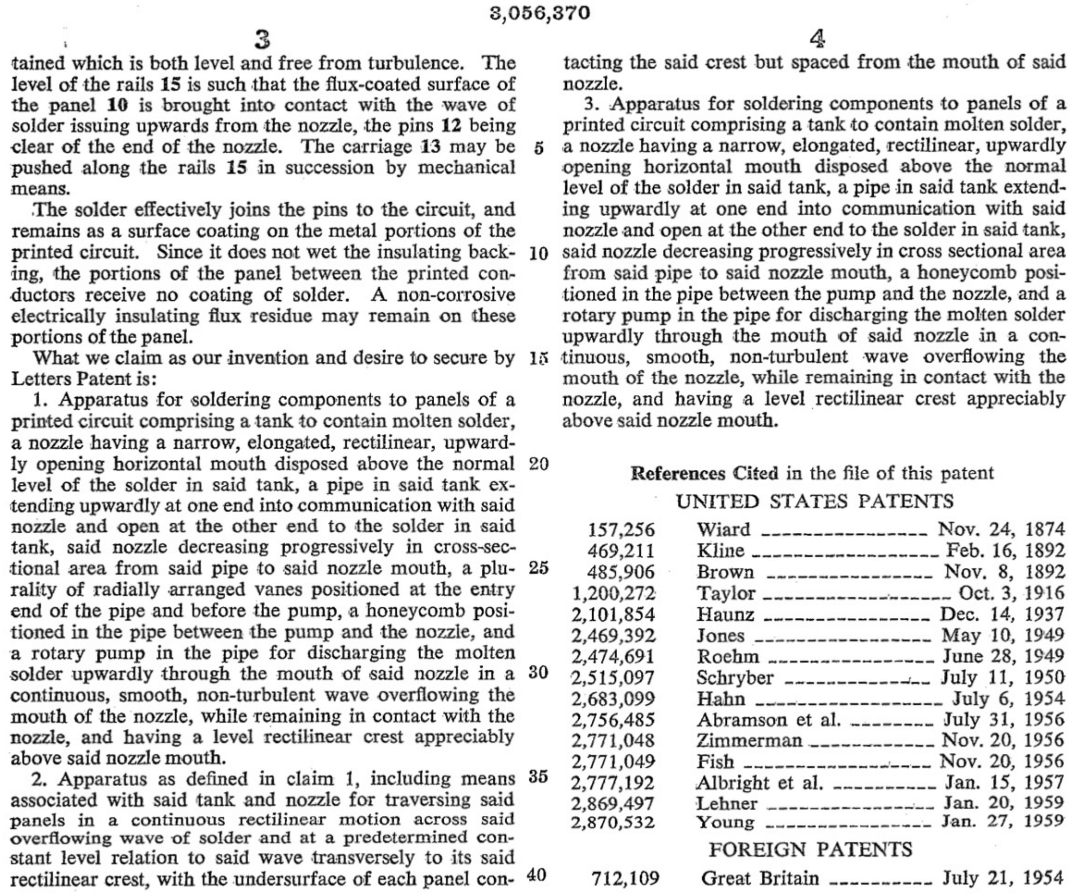
In the pipe **18** is a pump constituted by a bladed impeller **21**, driven by a variable speed electric motor **22** through a belt drive **23**. The pump delivers solder, derived from a point below the top level of the solder in the tank, upwardly through the mouth **20** of the nozzle as a wave, the expelled solder being directed against the undersurface of the panel **10** and cascading back into the tank.

It is important that the crest of the wave of solder should be level throughout its length. The nozzle **19** is accordingly designed so that there is no increase in its cross-sectional area from its lower end to its mouth. Consequently no eddies can form in the solder in the nozzle. In the case illustrated the cross-sectional area of the pipe **18** is 9 sq. ins. and the cross-section of the nozzle decreases progressively from its lower end to 4 sq. ins. at its mouth **20**, the mouth being 8 inches long and ½ inch wide. To avoid vortex formation by the pump **21**, vanes **24** are provided at the inlet to the pipe **18**. The nozzle **19** is shaped so that the speed of flow of the solder through it is even throughout its cross section, and the pipe **18** contains a flow straightener **25** of honeycomb form which ensures laminar flow of the solder.

Control of the height of the wave **23** of solder expelled from the mouth of the nozzle is effected by variation of the speed of the motor **22**. The wave of solder must make contact with the undersurface of the panel **10** but must not splash over into contact with the upper surface of the panel. Where the pins **12** project downwardly, as shown from the panel **10** the wave **23** of solder may need to have a height of up to ½ inch. If, however, the pins are turned to lie flat against the undersurface of the panel, the panel may be supported at a lower level and the height of the wave can be considerably reduced.

By suitably dimensioning the pipe **18** and the nozzle **19** and by providing the vortex-preventing vanes **24** and the flow straightener **25**, an overflow from the nozzle is ob-

Figure B.131: Rudolf Strauss invented wave soldering for printed circuits, or surface mount technology.



3,056,370

3

tained which is both level and free from turbulence. The level of the rails **15** is such that the flux-coated surface of the panel **10** is brought into contact with the wave of solder issuing upwards from the nozzle, the pins **12** being clear of the end of the nozzle. The carriage **13** may be pushed along the rails **15** in succession by mechanical means.

The solder effectively joins the pins to the circuit, and remains as a surface coating on the metal portions of the printed circuit. Since it does not wet the insulating backing, the portions of the panel between the printed conductors receive no coating of solder. A non-corrosive electrically insulating flux residue may remain on these portions of the panel.

What we claim as our invention and desire to secure by Letters Patent is:

1. Apparatus for soldering components to panels of a printed circuit comprising a tank to contain molten solder, a nozzle having a narrow, elongated, rectilinear, upwardly opening horizontal mouth disposed above the normal level of the solder in said tank, a pipe in said tank extending upwardly at one end into communication with said nozzle and open at the other end to the solder in said tank, said nozzle decreasing progressively in cross-sectional area from said pipe to said nozzle mouth, a plurality of radially arranged vanes positioned at the entry end of the pipe and before the pump, a honeycomb positioned in the pipe between the pump and the nozzle, and a rotary pump in the pipe for discharging the molten solder upwardly through the mouth of said nozzle in a continuous, smooth, non-turbulent wave overflowing the mouth of the nozzle, while remaining in contact with the nozzle, and having a level rectilinear crest appreciably above said nozzle mouth.

2. Apparatus as defined in claim 1, including means associated with said tank and nozzle for traversing said panels in a continuous rectilinear motion across said overflowing wave of solder and at a predetermined constant level relation to said wave transversely to its said rectilinear crest, with the undersurface of each panel contacting the said crest but spaced from the mouth of said nozzle.

4

3. Apparatus for soldering components to panels of a printed circuit comprising a tank to contain molten solder, a nozzle having a narrow, elongated, rectilinear, upwardly opening horizontal mouth disposed above the normal level of the solder in said tank, a pipe in said tank extending upwardly at one end into communication with said nozzle and open at the other end to the solder in said tank, said nozzle decreasing progressively in cross sectional area from said pipe to said nozzle mouth, a honeycomb positioned in the pipe between the pump and the nozzle, and a rotary pump in the pipe for discharging the molten solder upwardly through the mouth of said nozzle in a continuous, smooth, non-turbulent wave overflowing the mouth of the nozzle, while remaining in contact with the nozzle, and having a level rectilinear crest appreciably above said nozzle mouth.

COMPLETE SPECIFICATION.

Improvements in Soldering Fluxes.

We, FRY'S METAL FOUNDRIES LIMITED, of Tandem Works, Merton Abbey, London, S.W.19, a British Company, do hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement :—

This invention relates to rosin soldering fluxes. By the term " rosin " we mean the naturally occurring product, known sometimes as colophony, gum rosin, wood rosin or tree rosin, which is obtained from coniferous trees such as the pine tree.

A measure of the activity of a rosin flux is its spreading power on copper as determined by a spreading test. One known type of spreading test consists in placing on a thin sheet of copper a pellet, weighing 0.2 gms., of solder containing 42% by weight of tin and 58% by weight of lead. The pellet is surrounded with a small quantity of the flux under test, and the plate is then heated to 300° C. to melt the solder, and maintained at that temperature until the molten solder spreads no further. The average diameter of the area covered by the solder after the test is then determined.

Various organic activating agents have been proposed for incorporation in rosin fluxes for the purpose of improving their spreading power. Thus it has been proposed to incorporate in the flux from about 0.2—8% of cetyl pyridinium bromide (" Fixanol " C). " Fixanol " is a Registered Trade Mark.

Taking the diameter of the spread of the solder in accordance with the above test, when fluxed with plain rosin, as 1.00, the diameter of spread when the solder was fluxed with rosin activated with 4% by weight of " Fixanol " C was found to be 1.30.

One object of the invention is to effect a further improvement in the spreading power of rosin soldering fluxes.

According to the invention, the spreading power of rosin soldering fluxes is improved by incorporating therein up to 5% by weight, measured on the weight of the rosin, of hydrobromide of morpholine or of a hydrobromide of an N-alkyl substituted derivative of morpholine.

We find that best results are achieved with a flux containing up to 2% by weight of morpholine hydrobromide, the rest rosin, or a flux containing up to 4% by weight of N-methyl or N-ethyl morpholine hydrobromide, the rest rosin.

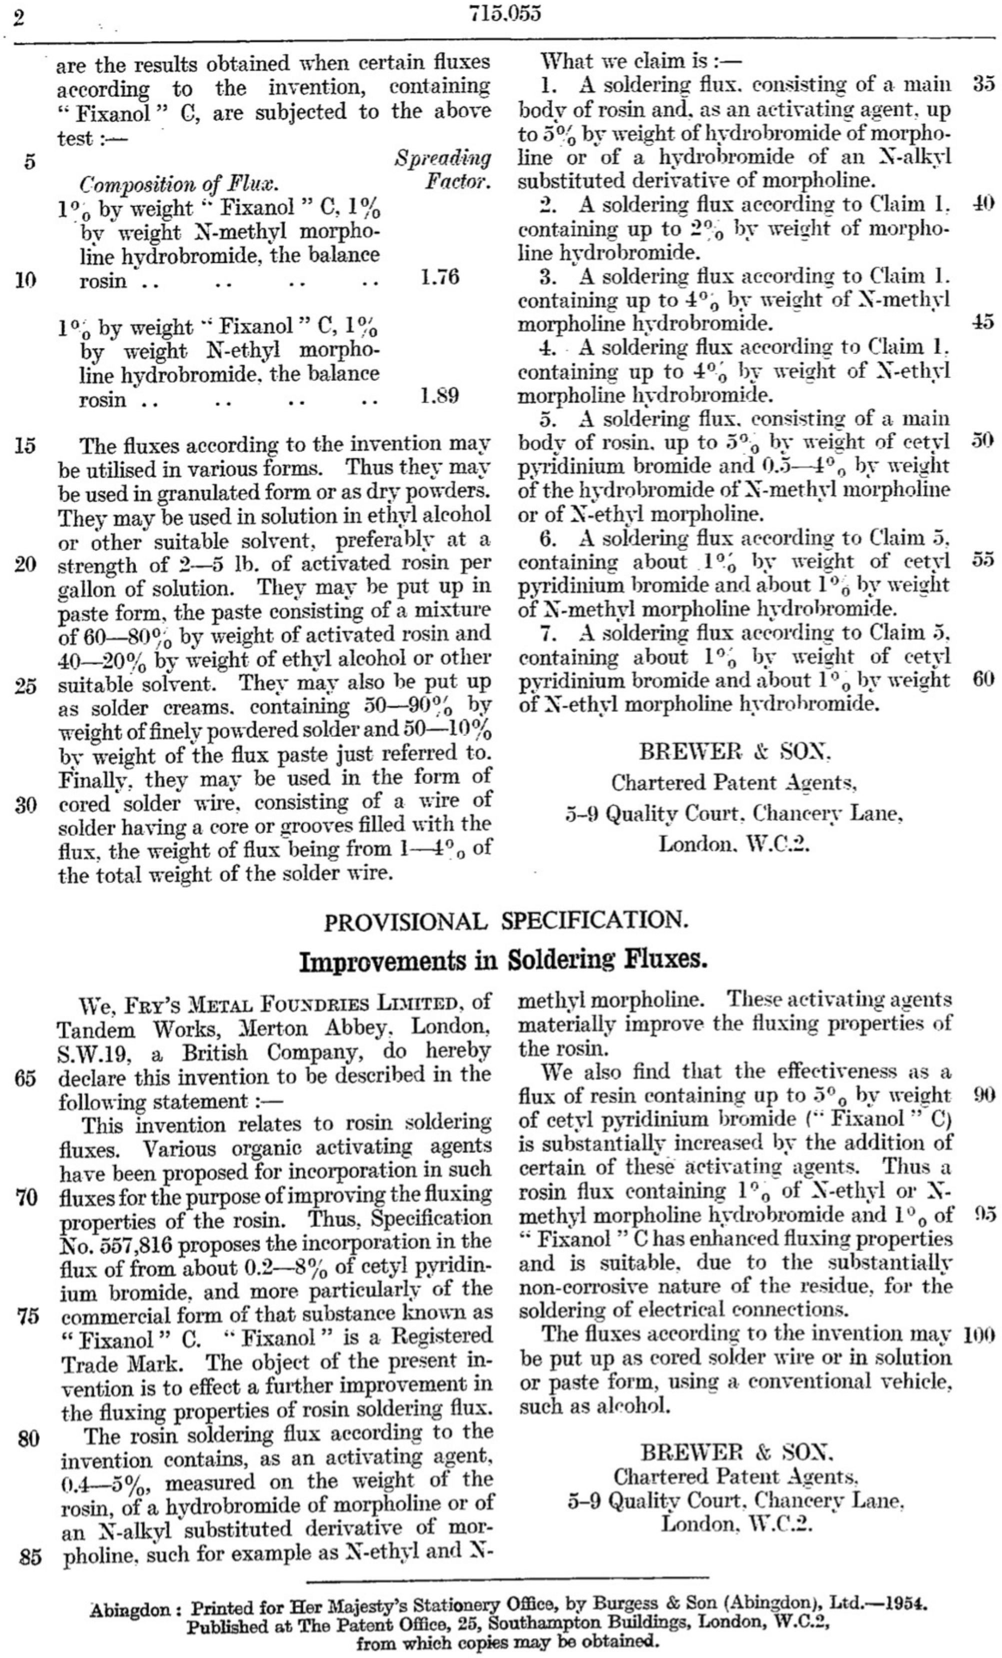
When such fluxes were tested by the above test the following results were obtained :—

Activating Agent.	*Spreading Factor.*
1% by weight morpholine hydrobromide	1.80
1% by weight N-methyl morpholine hydrobromide . .	2.30
2% by weight N-ethyl morpholine hydrobromide . .	2.27

In the case of fluxes for use when soldering electrical connections and for other applications in which it is of extreme importance that the residue should be substantially non-corrosive, we find it desirable to include in the flux a proportion of cetyl pyridinium bromide (" Fixanol " C) and to restrict the upper limit of the content of the morpholine derivative to 4%. The invention accordingly includes a rosin soldering flux containing up to 5% of " Fixanol " C and 0.5—4% of N-methyl morpholine hydrobromide or N-ethyl morpholine hydrobromide. These fluxes are found to give a residue which is substantially non-corrosive. The following

[*Price* : 2*s*. 8*d*.]

Figure B.133: Rudolf Strauss invented wave soldering for printed circuits, or surface mount technology.



are the results obtained when certain fluxes according to the invention, containing "Fixanol" C, are subjected to the above test:—

Composition of Flux.	*Spreading Factor.*
1% by weight "Fixanol" C, 1% by weight N-methyl morpholine hydrobromide, the balance rosin	1.76
1% by weight "Fixanol" C, 1% by weight N-ethyl morpholine hydrobromide, the balance rosin	1.89

The fluxes according to the invention may be utilised in various forms. Thus they may be used in granulated form or as dry powders. They may be used in solution in ethyl alcohol or other suitable solvent, preferably at a strength of 2—5 lb. of activated rosin per gallon of solution. They may be put up in paste form, the paste consisting of a mixture of 60—80% by weight of activated rosin and 40—20% by weight of ethyl alcohol or other suitable solvent. They may also be put up as solder creams, containing 50—90% by weight of finely powdered solder and 50—10% by weight of the flux paste just referred to. Finally, they may be used in the form of cored solder wire, consisting of a wire of solder having a core or grooves filled with the flux, the weight of flux being from 1—4% of the total weight of the solder wire.

What we claim is:—

1. A soldering flux, consisting of a main body of rosin and, as an activating agent, up to 5% by weight of hydrobromide of morpholine or of a hydrobromide of an N-alkyl substituted derivative of morpholine.
2. A soldering flux according to Claim 1, containing up to 2% by weight of morpholine hydrobromide.
3. A soldering flux according to Claim 1, containing up to 4% by weight of N-methyl morpholine hydrobromide.
4. A soldering flux according to Claim 1, containing up to 4% by weight of N-ethyl morpholine hydrobromide.
5. A soldering flux, consisting of a main body of rosin, up to 5% by weight of cetyl pyridinium bromide and 0.5—4% by weight of the hydrobromide of N-methyl morpholine or of N-ethyl morpholine.
6. A soldering flux according to Claim 5, containing about 1% by weight of cetyl pyridinium bromide and about 1% by weight of N-methyl morpholine hydrobromide.
7. A soldering flux according to Claim 5, containing about 1% by weight of cetyl pyridinium bromide and about 1% by weight of N-ethyl morpholine hydrobromide.

PROVISIONAL SPECIFICATION.

Improvements in Soldering Fluxes.

We, FRY'S METAL FOUNDRIES LIMITED, of Tandem Works, Merton Abbey, London, S.W.19, a British Company, do hereby declare this invention to be described in the following statement:—

This invention relates to rosin soldering fluxes. Various organic activating agents have been proposed for incorporation in such fluxes for the purpose of improving the fluxing properties of the rosin. Thus, Specification No. 557,816 proposes the incorporation in the flux of from about 0.2—8% of cetyl pyridinium bromide, and more particularly of the commercial form of that substance known as "Fixanol" C. "Fixanol" is a Registered Trade Mark. The object of the present invention is to effect a further improvement in the fluxing properties of rosin soldering flux.

The rosin soldering flux according to the invention contains, as an activating agent, 0.4—5%, measured on the weight of the rosin, of a hydrobromide of morpholine or of an N-alkyl substituted derivative of morpholine, such for example as N-ethyl and N-methyl morpholine. These activating agents materially improve the fluxing properties of the rosin.

We also find that the effectiveness as a flux of resin containing up to 5% by weight of cetyl pyridinium bromide ("Fixanol" C) is substantially increased by the addition of certain of these activating agents. Thus a rosin flux containing 1% of N-ethyl or N-methyl morpholine hydrobromide and 1% of "Fixanol" C has enhanced fluxing properties and is suitable, due to the substantially non-corrosive nature of the residue, for the soldering of electrical connections.

The fluxes according to the invention may be put up as cored solder wire or in solution or paste form, using a conventional vehicle, such as alcohol.

Jean Medawar and David Pyke. 2000. *Hitler's Gift: The True Story of the Scientists Expelled by the Nazi Regime.* New York: Arcade. p. 93.

Rudolf Strauss [...] met and became friends with Paul Eisler, a refugee from Austria, who had invented the printed electrical circuit board, which revolutionized the electronics industry. Strauss invented a technique for soldering thousands of electric connections in one operation. His 'wave soldering' machine, built in 1958, is still being made in a sophisticated form all over the industrial world. [...]

Recognition of Eisler's work took years. In late 1957 Lord Hailsham told the Royal Society that he rated the printed electric circuit as important an invention as penicillin or atomic fission.

Boris Chertok. 2005–2012. *Rockets and People.* 4 vols. Washington, DC: U.S. Government Printing Office. [https://www.nasa.gov/history/history-publications-and-resources/nasa-history-series/rockets-and-people/]

[Vol. 1, pp. 217–218:] We received "directives" and instructions thought up by God knows who, such as: "While inspecting German factories and laboratories, don't get carried away with intellectual achievements, but first and foremost compile a list of the types and number of machine tools, industrial engineering equipment, and instruments. As far as documentation and specialists are concerned, that is a matter of our judgement, and initiative will not be prohibited."

[Vol. 1, pp. 220–222:] DIARY ENTRY. 29–30 April 1945.

We are inspecting DVL [Deutsche Versuchsanstalt für Luftfahrt, or German Aviation Research Institute]. Administrative building. Archives, papers, personal documents—in safes. How do you open a safe? The sergeant and soldier detailed to us from the BAO already have experience. The soldier holds a large chisel against the safe doors. The sergeant, a "non-combatant" well over forty, delivers a precise, powerful blow with a heavy sledgehammer. Usually it opens the first time. Sometimes if the safe is especially "difficult," it takes three or four blows.The safes are full of reports with a red stripe,"Geheim!" (Secret) or "Streng Geheim!" (Top Secret). We leaf through the pages— reports, reports about all kinds of tests.

"DVL"—this is, after all, the equivalent of our TsAGI, LII, and Air Force NII all rolled into one. There is neither the time, nor the physical capability to read and study them.

The general has ordered us to list everything, load it into boxes, and send it by plane to Moscow. But where are we going to get as many boxes as we need? It turns out that the rear services and BAO do have them, and can organize everything! But there isn't even time to make a list of the reports.

Laboratory building. The aeronavigation laboratory is filled with benches for testing onboard instruments. The photochemical laboratory, the laboratory where materials are tested for strength and fatigue, vibration benches. A bombing and firing sights laboratory, accelerometer calibration units. And what magnificent drafting and designing equipment! I am envious of the German designers' workstations. Aside from the nice Kuhlman drafting unit, the swivel chair, and comfortable desk with lots of drawers, it is full of details, and everything has its place. Oh, this German love for details and this exactness, which has engrained such top-notch work into the culture.

The thing that every laboratory needs the most and that is in the shortest supply is the Siemens four-mirror oscillograph. There we found various models: two-, four-, and six-mirror models. Without them, conducting research on rapidly occurring dynamic processes is impossible. This is a new epoch in the technology of measurements and engineering research. In Moscow, at NII-1 we had only one six-mirror oscillograph for the entire institute. And these Germans had so many! No,we no longer felt the hatred or the thirst for vengeance that had boiled in each of us earlier. Now it was even a pity to break open these high quality steel laboratory doors and to entrust these diligent but not very careful soldiers with packing priceless precision instruments into boxes.

But faster, faster—all of Berlin is waiting for us! [...]

The electric instrument laboratory was fantastic! There were so many unique (for us) instruments of all types and ranges from the world-renowned German firms Siemens, Siemens und Halske, Rohde & Schwarz, and the Dutch firms Philips, Hartmann-Braun, and Lorentz! And again— photographic enlargers, slide projectors, movie projectors, chemicals, bulky stationary cameras, cine-theodolites, phototheodolites, and optics of incomprehensible purpose...

We christened a separate building the electrophysics building because of its contents. Electronic low- and high-frequency frequency meters, wave meters, precision noise meters, octave filters, harmonic analyzers, nonlinear distortion factor meters, motor generators and dynamotors for various voltages, even the scarce cathode ray (now called electronic) oscillographs. The richest building of all was the one containing radio and acoustical measurement equipment.

We are writing the addresses of our firms on the boxes:“P.O. Box” so-and-so. But what will really happen to this stuff? Who will meet the airplanes in Moscow?”

[Comments added by Chertok in the 1990s:] After much time had passed, I indeed never found a single report from that mass of secret and top-secret reports that I had sent from Adlershof. They were dispersed over LII, TsAGI, NISO, and other aircraft industry institutions. Only about one-tenth of the instruments that we had sent ended up at NII-1, provoking a justifiable reaction from my immediate chief. At NII-1 in Likhobory, they began preparing the next, independent expedition to Germany. This time, on their own airplane.

[Vol. 1, p. 230:] In the ensuing days, we continued to investigate the Askania facility. The factory had a broad spectrum of interesting items and competed with Siemens for our interest. We discovered another large factory and design bureau in Mariendorf. Here I finally found intact actuators for the V-2, as well as similar actuators for aircraft autopilots. Sets of autopilot equipment intended for delivery were assembled on the test stands. With astonishment, we discovered shops with submarine periscopes, periscope range finders, bombsights, and anti-aircraft fire control equipment (PUAZO). There were special cockpits equipped for crew training and testing where blind flight conditions were simulated. There was a rather large shop that was involved with purely optical production. Optical glass polishing machines stood next to the finished products—virtual mountains of lenses of various diameters up to 50 centimeters! The test laboratories were excellently equipped. They contained pressure chambers, thermal vacuum chambers, vibration stands, and rainfall simulators. Every area was equipped with all-purpose and special-purpose measurement instruments and also with our dream instrument: the Siemens multi-mirror oscillograph!

[Vol. 1, pp. 231–233:] DIARY ENTRY. 9 May 1945.

Our visit to the Telefunken factory in Zehlendorf was very interesting.

Originally it was a radio tube factory, but in the last few years it has switched almost completely to radar. In contrast to many other enterprises here we found almost all of the personnel, including chief engineer Wilki and his immediate staff. Chistyakov and I already spoke German rather briskly. For that reason we did not need an interpreter. Wilki and the production chief showed us the factory and laboratory. Wilki directed research in the field of centimetric waves. His laboratory, which is not located within this factory, has been conducting a thorough study of American and British radar installed on aircraft as well as radar sights for bombing and reconnaissance.

According to the assessments of the German specialists, the Americans and Brits have been very successful in the field of radar—especially in submarine warfare. Their aircraft detect periscopes from tens of kilometers away. In this regard, they have also worked a great deal on instruments to alert submarine crews that they have been illuminated by aircraft radar.

At the factory, they were involved in the series production of aircraft radar using American and British experience. The radar manufacturing shops were well equipped with electronic monitoring instruments.The factory turned out to be relatively new. They finished building it in 1939. In all, counting the Ostarbeiter, some 6,000–7,000 people worked there. Of that number, 3,000 were engineers and technicians. They experienced no shortage of materials or supplies.

The Lorenz and Blaupunkt companies provided large television screens for the radar and receivers.“But you didn’t study Soviet radar?”

According to information from our military, they did not find radar on a single one of your airplanes. And among the captured materials that they were able to provide us during our troops’ offensive, there was also nothing of interest.We decided that the Russians had safeguarded this technology so well that it did not fall into the hands of our military.”

I think that he spoke of “safeguarding” to be polite. In actual fact, they had surmised that during the war we had virtually no aircraft radar and radar sights. [...]

We wore them out with questions about other firms and studies. Like all radio and electronics specialists, they were well informed about related firms and developments and told us that Telefunken and Lorentz were involved primarily in radar technology for air defense purposes, while Askania and Siemens were involved in remote control. Over the past six months, many directors along with staff and laboratories had been moved to Thuringia and Westphalia.They knew that the secret weapon, the “vengeance rocket,” was being made in Peenemünde. None of them had ever been there—it was very secret. But other divisions of Telefunken were building ground-based radars and stations for the radio control of rockets.

The tube shops were excellently equipped. Here they were making magnetron tubes with a pulse power of up to 100 kilowatts!

That is how we first heard about the Kaiser Wilhelm Institute in Dahlem. Later, while exchanging impressions about everything that we had seen at Telefunken and then at Lorentz, we mused how, in spite of the strictest secrecy, scientific knowledge and its progress are ultimately shared between countries.Thoughts are transmitted between scientists over some sort of telepathic channel. Not only did we all toil separately, but we believed, and quite rightly, that the Germans were our mortal enemies. Our allies, out of consideration for secrecy, hardly shared their work with us. Nevertheless, with the exception of small lapses, parallel developments were taking place in the scientific fields of radar, nuclear energy, and rocket technology.

[Vol. 1, pp. 234–235:] DIARY ENTRY. 10 May 1945.

We barely managed to make our way to the Lorentz company in Tempelhof. [...]

Even before our visit, the factory itself had been taken over by the "trade union" officers of Moscow's radio factories.They had also appropriated from the basement, but did not interfere with our inspection. We talked with the German specialists for about two hours.They showed us transmitters for 3- and 9-centimeter range radars. It was interesting that the laboratory, which specialized in the development of television receivers, was quickly reoriented for instruments with large radar observation cathode ray tubes.

The factory produced ground-based radio stations with large rotating antennas for guiding aircraft to their airfields. We ascertained that in practice these radar stations were also used to control air battles in the direct coverage zone. We were surprised by the number of circular scanning stations with large screens that made it possible to see hostile aircraft and distinguish them from one's own. The Germans claimed that they had already produced around one hundred of these stations. It was hard to believe, considering the exceptional complexity and labor intensity of the system. Development of the Freya radar began as early as 1938. It enabled the detection of an aircraft at a distance of up to 120 kilometers. The Würzburg radar with a spherical antenna was developed to control anti- aircraft fire. Night fighters homed in on the target using the powerful "Würzburg Giant" radar station. At the beginning of the war, all of the German radar technology was in the decimeter range. The German engineers advised us, "Our war with the Brits was fought not only on the battlefield and in the air, but also in laboratories.They had already achieved great success as early as 1942 thanks to their daring switch to the centimeter range. At that time we did not have the same tube technology."

[Vol. 1, p. 235–238] He was Aleksandr Ivanovich Shokin, representing the GKO Council on Radar. At that time I had no way of knowing that I had met with the future deputy minister of the radio engineering industry, who would become the minister of the electronic industry. I would have the occasion to meet with him more than once in the latter period of his hypostases, almost up until his demise in 1986.

At that time in Berlin he said bitterly that, in spite of serious scientific achievements, our radio engineering and electronics industry was undoubtedly poorly developed compared with what we were seeing here. On this visit, as during all of our visits to German factories and laboratories, we were stunned by the abundance of instruments—both universal and special-purpose, especially in comparison to their scarcity at home. Vacuum-tube voltmeters, oscillographs, audio-signal generators, filters of all kinds, standard amplifiers, wave meters, frequency meters, etc., etc.—and all of it was high quality. Instrument models that we had considered precious before the war were continually showing up here. Not one of our institutes, factories, or laboratories could even imagine such abundance.

But indeed the war of the laboratories was not only a war of pure intellects. Each "intellect" had to be armed with the most advanced instruments for scientific research. This required a well-developed instrumentation industry.

Alas, even today, fifty years after the war, we do not fully appreciate the strength of the research scientist's laboratory weaponry, much less that of the engineer. Incidentally, one of the burning topics for the past ten years, our scandalous lag behind in the field of personal computers, has not only economic but also ideological roots: indifference to the specific needs of the human being as an individual, since, in the opinion of the country's senior leadership, above all, we had to be ahead of the "entire planet" in the smelting of steel and iron, in coal mining, oil production, and in the number of tractors and machine tools produced.

These garish indicators got through to the dullest bureaucrats at the highest levels of the Party-State hierarchy, but for the longest time they did not comprehend why it was necessary to lead or at least be on the level of an average capitalistic country in terms of providing measurement technology, not to mention expensive computers. And when it suddenly occurred to us,it turned out that we were one of the most backward countries in the world in that field.

Well, these are modern issues, but back then in Berlin and its surrounding areas we continued to collect worthwhile literature and send it to Moscow. I also insisted that we send back a wide variety of measurement technology.

Measurement equipment was my weakness during our collection of "spoils." I carefully prepared the cases containing instruments that had been retrieved by Red Army soldiers from the aerodrome maintenance battalion, then and waited for "my" airplane to deliver them to "my" institute.

By the middle of May, our *troika*—reinforced by several more specialists from NISO and LII, including Professor Sergey Nikolayevich Losyakov, had already put together a more or less clear picture of the instrument and radio industry in Greater Berlin. Our list contained more than thirty enterprises, each of which surpassed our own in terms of technology and production. The most interesting were the laboratories and factories of Askania, Telefunken, Lorenz, Siemens, AEG, Blaupunkt, and Loewe Radio.

For us it was a novelty that the company List, which specialized only in the development and mass-production of multi-pin plug connectors, existed and flourished among the Germans. They had produced hundreds of thousands of connectors for German aircraft and rockets.The concept was very simple, but the engineering and production involved were fundamentally new to us. This innovation developed in response to the extreme complexity of the electrical circuits used in flying vehicles. The connectors enhanced rapid assembly and allowed electrical components to be connected and disconnected reliably during the repair and testing of individual compartments.

The very term *shteker*, or plug connector, made its way into the Russian language from the Germans after the war. Throughout history much has been transferred to the victors from the vanquished. Only after the war did we come to appreciate what a tremendous technical role such a seemingly simple device as the plug and socket connector was destined to play in aircraft and rocket technology! The Germans spent years developing reliable connectors, and introduced into aircraft and rocket technology the standard List *shteker*, which had from two to thirty pins. We needed three years to reproduce connectors that were as reliable. However, during our first years of mastering rocket technology they gave us a lot of trouble.

Now our industry produces connectors—both tiny and enormous, airtight, onboard and ground-based—to connect and remotely disconnect more than one hundred electric circuits. Despite all of these achievements, the problem of connector technology remains one of the most complex in the entire world. This is why there are booths at every international aerospace exhibition advertising hundreds of modifications of quick and reliable cable connectors. Dozens of powerful companies in many countries produce them by the millions.

We were interested not only in individual factories, but also in the organization and structure of the instrument and radar industry. German companies worked on a lot of technical problems on their own initiative, without waiting for instructions "from the top." They did not need the decisions of the Gosplan or People's Commissariats, without which not a single factory of ours could produce anything. Before the war, the electric measuring technology, instrument, and radio industries had developed rapidly to conquer the entire European market, and their products had successfully competed with those of the United States. The companies Hartmann-Braun, Telefunken, Anschütz, Siemens, Lorentz, AEG, Rohde & Schwarz, Askania, and Karl Zeiss enjoyed worldwide fame long before World War II. This created a solid technological base, which we simply did not have in these industries on the required scale at the beginning of the war.

Our general-purpose electrical instrument industry, our aircraft industry, and also our nautical instrumentation industry were all housed in just a few buildings in Moscow and Leningrad (Elektropribor, Teplopribor, and Svetlana in Leningrad; Aviapribor, the Lepse Factory, Elektrozavod, and Manometr in Moscow).

It is revealing that when we began to reproduce technology for the V-2 rocket after the war and develop our own new rockets, we found out that in our country there was only one factory, Krasnaya Zarya in Leningrad, that was able to manufacture such a mundane device as the multi-contact electrical relay. In Germany, Telefunken had three such factories and Siemens had at least two. This is one of the reasons that German weapons production did not drop, but continuously increased until mid-1944, despite the continuous bombing that Allied aviation inflicted on German cities.

B.3 Integrated Circuits

[Even further miniaturization of electronics required moving from individual electronic components to integrated circuit chips that could contain large numbers of components on the same semiconductor substrate.

In 1949, Werner Jacobi (German, 1904–1985) filed a West German patent application on integrated circuits on behalf of Siemens & Halske. Since there were a large number of German inventors who filed patents on their wartime work when the (West) German patent office reopened in 1949, it is quite likely that Jacobi's patent application was based on experimental work that he had conducted at Siemens & Halske during the war (pp. 2816–2817).

Kurt Lehovec (Bohemian/Austrian/Czech, 1918–2012) developed advanced semiconductor devices for Germany in Prague during the war. After the war he was extensively interrogated by the United States and then moved to the United States (as part of Operation Paperclip), where he filed patents on transistors, integrated circuits, and light emitting diodes. See pp. 2757–2763, 2818–2832, and 2895–2910. Lehovec's integrated circuit designs may well have been based on wartime work, but even if they were early postwar ideas, they preceded the claims of American engineers who later worked on integrated circuits.

Other German-speaking scientists developed transistor fabrication methods that made integrated circuits practical:

- Herbert Kroemer (German, 1928–) invented the drift transistor in 1953, the double-heterostructure laser diode in 1963, and III-V semiconductor heterostructures in 1966. (See pp. 1111, 2833–2845, and 2917–2922.) He won the Nobel Prize in Physics in 2000 (p. 1104).

- Jean Hoerni (Swiss, 1924–1997) and Eugene Kleiner (Austrian, 1923–2003) devised methods of manufacturing silicon transistors at Fairchild Semiconductor; see pp. 1101 and 2846–2861. Through Fairchild and their later companies and investments, they also helped to develop Silicon Valley.

- Karl Heinz Zaininger (German, 1929–) developed modern methods for fabricating field effect transistors (pp. 1102 and 2862–2876).

As shown on pp. 2877–2887, Helmut Gröttrup (German, 1916–1981) and Jürgen Dethloff (German, 1924–2002) invented the smart card, or chip card, in 1966. Earlier, Gröttrup developed avionics systems in Germany during the war and led the German-speaking contributions to the postwar Soviet ballistic missile program (pp. 1874–1881).

As with transistors and printed circuits, much more research should be conducted to determine how much work on integrated circuits was conducted in the German-speaking world during the war, and how much impact German-speaking scientists and knowledge had on the postwar development of integrated circuits in other countries.]

Werner Jacobi (1904–1985) filed a patent application on integrated circuits in 1949 (based on wartime work?)

833 366

Wenn der Halbleiter in der zur Zeit bekannten Form vielleicht auch nicht geeignet ist, in allen Fällen von Verstärkeranordnungen an die Stelle einer Elektronenröhre zu treten, so scheint seine Anwendung jedoch für bestimmte Zwecke vorteilhaft zu sein. So dürfte er sich u. a. besonders für Schwerhörigengeräte eignen. Aus dieser Zweckbestimmung heraus entsteht die Aufgabe, deren Lösung selbstverständlich auch für jegliche andere Anwendung des Halbleiterverstärkers grundsätzliche Bedeutung z. B. aus preislichen Gründen hat, einen solchen Halbleiterverstärker nicht nur billig, sondern auch raum-, gegebenenfalls auch gewichtssparend aufzubauen. Zur Lösung dieser Aufgabe wird erfindungsgemäß vorgeschlagen, auf den Halbleiter mehrere in verschiedenen Schalt- bzw. Verstärkerstufen wirkende Elektrodensysteme aufzusetzen.

Nimmt man z. B. an, daß der in der Figur als geschnittene Halbkugel gezeigte Halbleiter *K* einen Durchmesser von 2 mm hat, so können je nach der konstruktiven Gestaltung und Anordnung der einzelnen Elektroden mehrere Elektrodensysteme in je einem Abstand von 0,2 mm bei bekanntem Elektrodenabstand von 0,05 mm aufgesetzt werden, ohne daß eine gegenseitige Beeinflussung der einzelnen Systeme eintritt. Diese Elektrodensysteme können dann in bekannter Weise durch Kopplungsglieder zu einem mehrstufigen Halbleiterverstärker zusammengeschaltet werden.

Hierbei können die Kopplungsglieder gegebenenfalls aus einer Halbleiteranordnung bestehen, welche zusätzlich aufgewendet oder durch Einsatz von auf den Halbleiter schon aufgesetzten Elektrodensystemen gebildet werden. Zu diesem Zweck wird die sonst als Eingang dienende Elektrode als Ausgang des Kopplungsgliedes benutzt und umgekehrt, da der Halbleiterverstärker einen niederohmigen Eingang und einen hochohmigen Ausgang benötigt. Man erspart also auf Grund der vorliegenden Erkenntnis, den Halbleiter mit vertauschtem Eingang und Ausgang als Transformator zu benutzen, mit Rücksicht auf diese Eingangs- und Ausgangsverhältnisse besonders auszubildende Kopplungsglieder. In der Figur sind fünf solcher Systeme mit den beispielsweise einzuhaltenden Maßen schematisch angedeutet.

PATENTANSPRÜCHE:

1. Halbleiterverstärker, dadurch gekennzeichnet, daß auf den Halbleiter mehrere in verschiedenen Schalt- bzw. Verstärkerstufen wirkende Elektrodensysteme aufgesetzt werden.

2. Halbleiterverstärker, insbesondere nach Anspruch 1, dadurch gekennzeichnet, daß bestimmte Elektrodensysteme nach Vertauschung von Eingangs- in Ausgangselektrode und umgekehrt als Kopplungsglieder zwischen anderen Elektrodensystemen dienen.

Figure B.138: Werner Jacobi filed a patent application on integrated circuits in 1949, which was quite likely based on experimental work that he had conducted during the war.

TRANSISTOR COMBINATIONS
Kurt Lehovec, Williamstown, Mass., assignor to Sprague Electric Company, North Adams, Mass., a corporation of Massachusetts
Filed June 9, 1955, Ser. No. 514,220
5 Claims. (Cl. 250—211)

This invention relates to transistor combinations, more particularly to combinations by which signals can be amplified.

Among the objects of the present invention is the provision of novel transistor combinations which have improved amplification characteristics as compared to prior art combinations.

The above as well as additional objects of the present invention will be more clearly understood from the following description of several of its exemplifications, reference being made to the accompanying drawings wherein:

FIG. 1 is a representative showing, partly in schematic form, of one embodiment of a unipolar transistor;

FIG. 2 is a schematic showing of a modified unipolar transistor combination according to the present invention;

FIGS. 3 and 4 are diagrammatic views of prior art forms of unipolar transistors; and

FIGS. 5 and 6 are pictorial representations of modified unipolar semiconductor devices according to the invention.

A unipolar transistor was fully described by W. Shockley in an article, entitled "A Unipolar Field Effect Transistor," which appeared in the November 1952 issue of the Proceedings of the IRE, Volume 40, No. 11, pages 1365–1376. Briefly the device consists essentially of a semiconductor having a conducting channel with an adjacent equipotential layer or gate electrode and a space charged region in the semiconductor between the channel and the equipotential layer. By varying the potential between the channel and the equipotential layer, the effective channel width can be varied and the channel current which is being carried therein is similarly varied. When the current flows along the channel the potential thus varies along the channel, which in turn results in a potential variation between the channel and the equipotential layer. As a result, the width of the space charged region varies along the channel and with sufficiently high potentials imposed on opposite ends of the channel, the space charged region may extend completely over the channel rendering it insulating or may even cause breakdown if maintained. This limits the usefulness of the device. It is thus the intent of this invention to render these unipolar field effect transistors less susceptible to breakdown or alternatively, susceptible to much higher current gain, as well as reliability of operation when used with signal voltages of substantial amplitudes.

It has been found possible to improve the operating curve of the unipolar transistor so as to handle larger signal voltages as well as to produce much higher power gains, through provision of two parallel current flows in a unipolar transistor so as to maintain the width of the charged layer at a uniform dimension. This is readily accomplished as indicated by providing a potential drop along the gate electrode which is the same or similar to the voltage drop along the channel.

For better understanding of this invention refer to FIG. 1, wherein the combination here illustrated has a semiconductor body **10** with two portions **12**, **14** of opposite types of conductivity. Portion **12**, for example, is indicated as having p-conductivity and portion **14** n-conductivity. Between them there is a p–n junction **15** that is relatively elongated. Intermediate of the ends of the rectangular crystal **10** are two depressions **16** and **17**, the

2

former extending down into the p-region of conductivity and the latter extending into the n-region of conductivity. These grooved areas extend fully across the face of the crystal and are readily produced by magnetostrictive cutting followed by a jet electrochemical etch, both techniques of which are well-known to the art. The thickness of the web formed in the crystal between the points of maximum depth of depressions **16** and **17** is preferably very thin, not over 20 mils thick, and preferably much thinner, in the order of 2 mils thickness. Of course, it is to be realized that this lower limit of distance between the two depressions is dictated by the structural strength requirements which the device must exhibit. However, for optimum operational characteristics the thin region separation is desirable although the crystal can readily be supported by outside insulators, such as plastic holders, etc.

At opposite ends of each portion **12**, **14** are positioned electrodes represented at **18**, **20**, **22**, **24**. A bias supply **25** is connected between a correspondingly located pair of electrodes **18**, **22**, on the respective semiconductor portions, to bias the portions in the direction that blocks the passage of current from one body to the other. In the construction of FIG. 1 the bias supply also impresses varying signals "E" between the same electrodes **18**, **22**.

Electrodes **18**, **20** are shown as connected to an output circuit **26** including a source of potential **28** and an output load **30**. Another output circuit **32** is similarly connected between electrodes **22** and **24** and similarly polarized. For purposes of discussion the n-conductivity having electrodes **22** and **24** is designated the "channel" while the p-region with its electrodes **18** and **20** is designated the "gate."

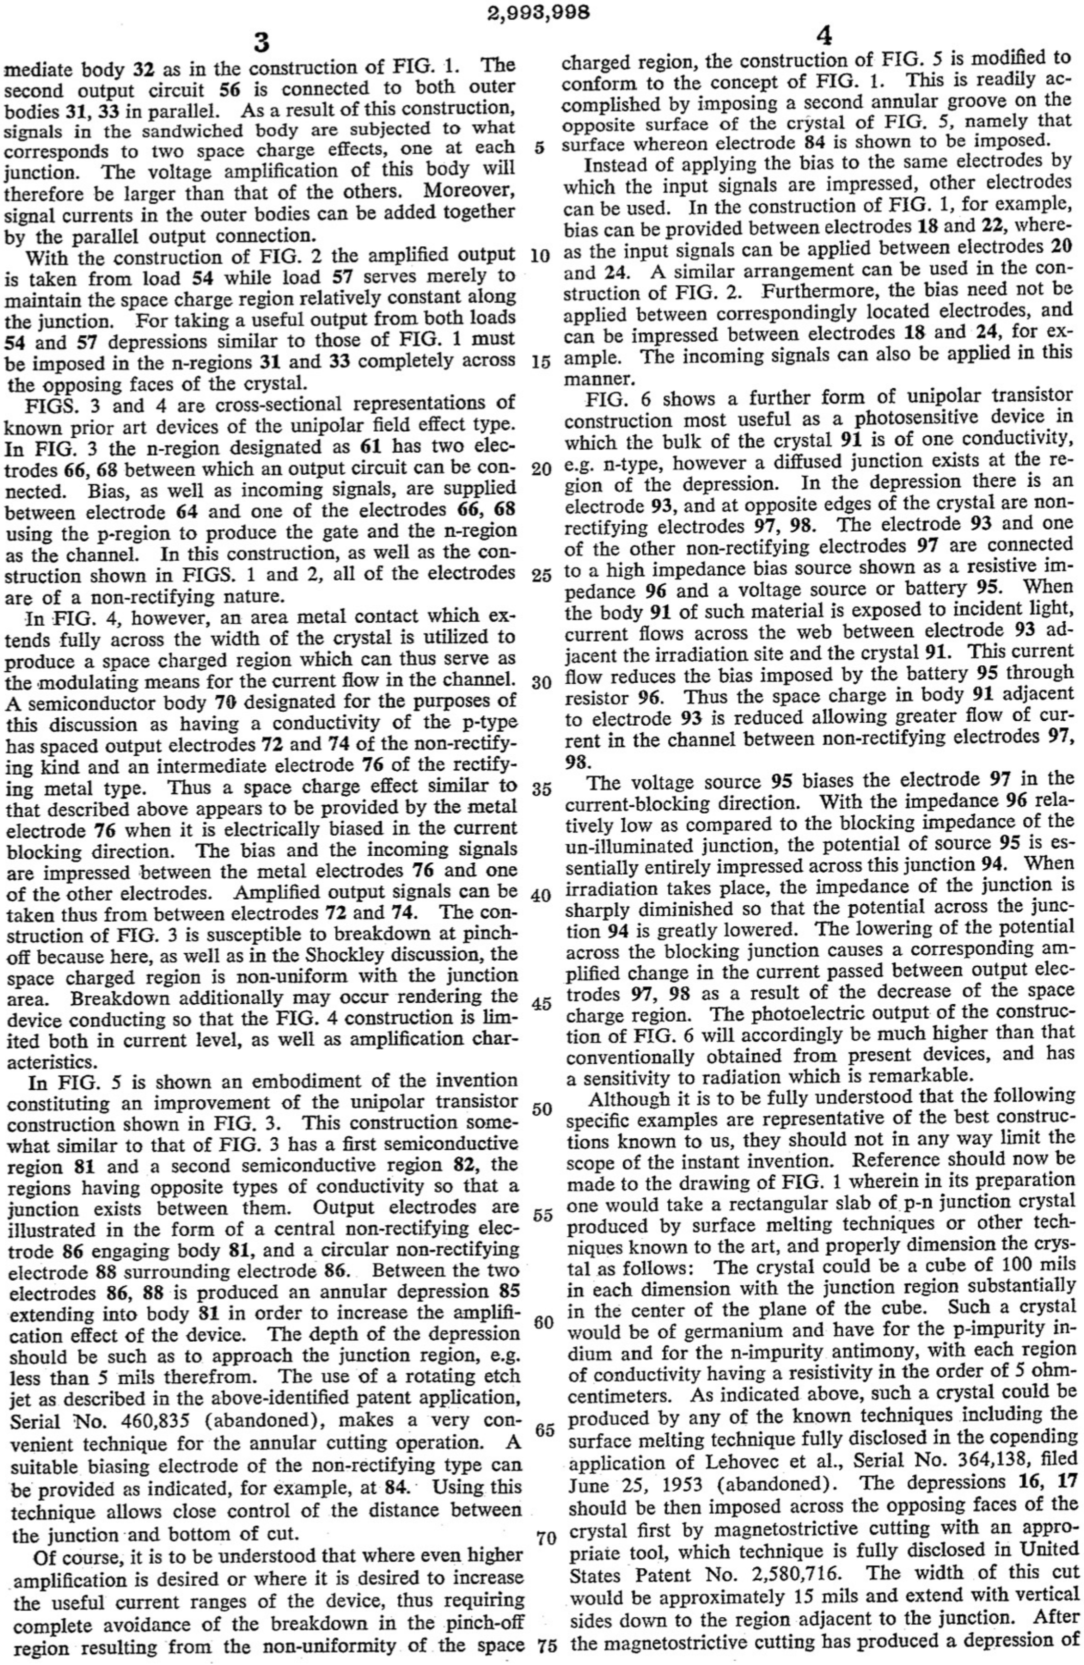
The entire combination of FIG. 1 makes a so-called unipolar transistor amplifier in which the junction **15** provides a space charge effect that is substantially uniform along its length. For the greatest uniformity the semiconductor portions **12**, **14** should have corresponding electrical resistivities, e.g. of the order of 5 ohm-centimeters, and the output circuits should be arranged to apply corresponding potentials so that there are corresponding potential gradations along the effective length of the junction in both the channel and gate portions. The resistivities are controlled by the concentration of doping ingredients added to the respective semiconductor bodies either by diffusion into the solid body, surface melting or by alloying with a liquefied mass from which the bodies are formed.

A feature of the construction of FIG. 1 is that two different amplified output signals are provided so that one can be used independently of the other as a monitor, for example. In addition, where maximum power output is desired, both output signals can be combined as by transformer coupling. This is made possible by the use of the two depressions **16** and **17** so that the dimension of the space charge region could materially effect the current flow in the channel. Herein, in FIG. 1, for one part of the circuit including load **30** the n-region is the channel and the p-region the gate, and for the other part of the circuit including load **34**, vice versa.

FIG. 2 shows a modified construction of the unipolar transistor type in which one region of conductivity is sandwiched between regions of opposite conductivity. The three regions are illustrated as **31**, **32**, **33**, being produced by techniques well-known in the art. Blocking bias, as well as incoming signals, are supplied by source **36** between the intermediate body **32** on the one hand, and the outer two which can be connected together. Electrodes **38**, **40**, **42**, **44**, **46** and **48** are provided on the individual bodies as in the construction of FIG. 1.

The junction construction of FIG. 2 also has two output circuits **52**, **56**. One of these is connected to inter-

Figure B.141: Kurt Lehovec developed semiconductor devices for Germany during the war. After the war he was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits.



2,993,998

3

mediate body **32** as in the construction of FIG. 1. The second output circuit **56** is connected to both outer bodies **31, 33** in parallel. As a result of this construction, signals in the sandwiched body are subjected to what corresponds to two space charge effects, one at each junction. The voltage amplification of this body will therefore be larger than that of the others. Moreover, signal currents in the outer bodies can be added together by the parallel output connection.

With the construction of FIG. 2 the amplified output is taken from load **54** while load **57** serves merely to maintain the space charge region relatively constant along the junction. For taking a useful output from both loads **54** and **57** depressions similar to those of FIG. 1 must be imposed in the n-regions **31** and **33** completely across the opposing faces of the crystal.

FIGS. 3 and 4 are cross-sectional representations of known prior art devices of the unipolar field effect type. In FIG. 3 the n-region designated as **61** has two electrodes **66, 68** between which an output circuit can be connected. Bias, as well as incoming signals, are supplied between electrode **64** and one of the electrodes **66, 68** using the p-region to produce the gate and the n-region as the channel. In this construction, as well as the construction shown in FIGS. 1 and 2, all of the electrodes are of a non-rectifying nature.

In FIG. 4, however, an area metal contact which extends fully across the width of the crystal is utilized to produce a space charged region which can thus serve as the modulating means for the current flow in the channel. A semiconductor body **70** designated for the purposes of this discussion as having a conductivity of the p-type has spaced output electrodes **72** and **74** of the non-rectifying kind and an intermediate electrode **76** of the rectifying metal type. Thus a space charge effect similar to that described above appears to be provided by the metal electrode **76** when it is electrically biased in the current blocking direction. The bias and the incoming signals are impressed between the metal electrodes **76** and one of the other electrodes. Amplified output signals can be taken thus from between electrodes **72** and **74**. The construction of FIG. 3 is susceptible to breakdown at pinch-off because here, as well as in the Shockley discussion, the space charged region is non-uniform with the junction area. Breakdown additionally may occur rendering the device conducting so that the FIG. 4 construction is limited both in current level, as well as amplification characteristics.

In FIG. 5 is shown an embodiment of the invention constituting an improvement of the unipolar transistor construction shown in FIG. 3. This construction somewhat similar to that of FIG. 3 has a first semiconductive region **81** and a second semiconductive region **82**, the regions having opposite types of conductivity so that a junction exists between them. Output electrodes are illustrated in the form of a central non-rectifying electrode **86** engaging body **81**, and a circular non-rectifying electrode **88** surrounding electrode **86**. Between the two electrodes **86, 88** is produced an annular depression **85** extending into body **81** in order to increase the amplification effect of the device. The depth of the depression should be such as to approach the junction region, e.g. less than 5 mils therefrom. The use of a rotating etch jet as described in the above-identified patent application, Serial No. 460,835 (abandoned), makes a very convenient technique for the annular cutting operation. A suitable biasing electrode of the non-rectifying type can be provided as indicated, for example, at **84**. Using this technique allows close control of the distance between the junction and bottom of cut.

Of course, it is to be understood that where even higher amplification is desired or where it is desired to increase the useful current ranges of the device, thus requiring complete avoidance of the breakdown in the pinch-off region resulting from the non-uniformity of the space charged region, the construction of FIG. 5 is modified to conform to the concept of FIG. 1. This is readily accomplished by imposing a second annular groove on the opposite surface of the crystal of FIG. 5, namely that surface whereon electrode **84** is shown to be imposed.

4

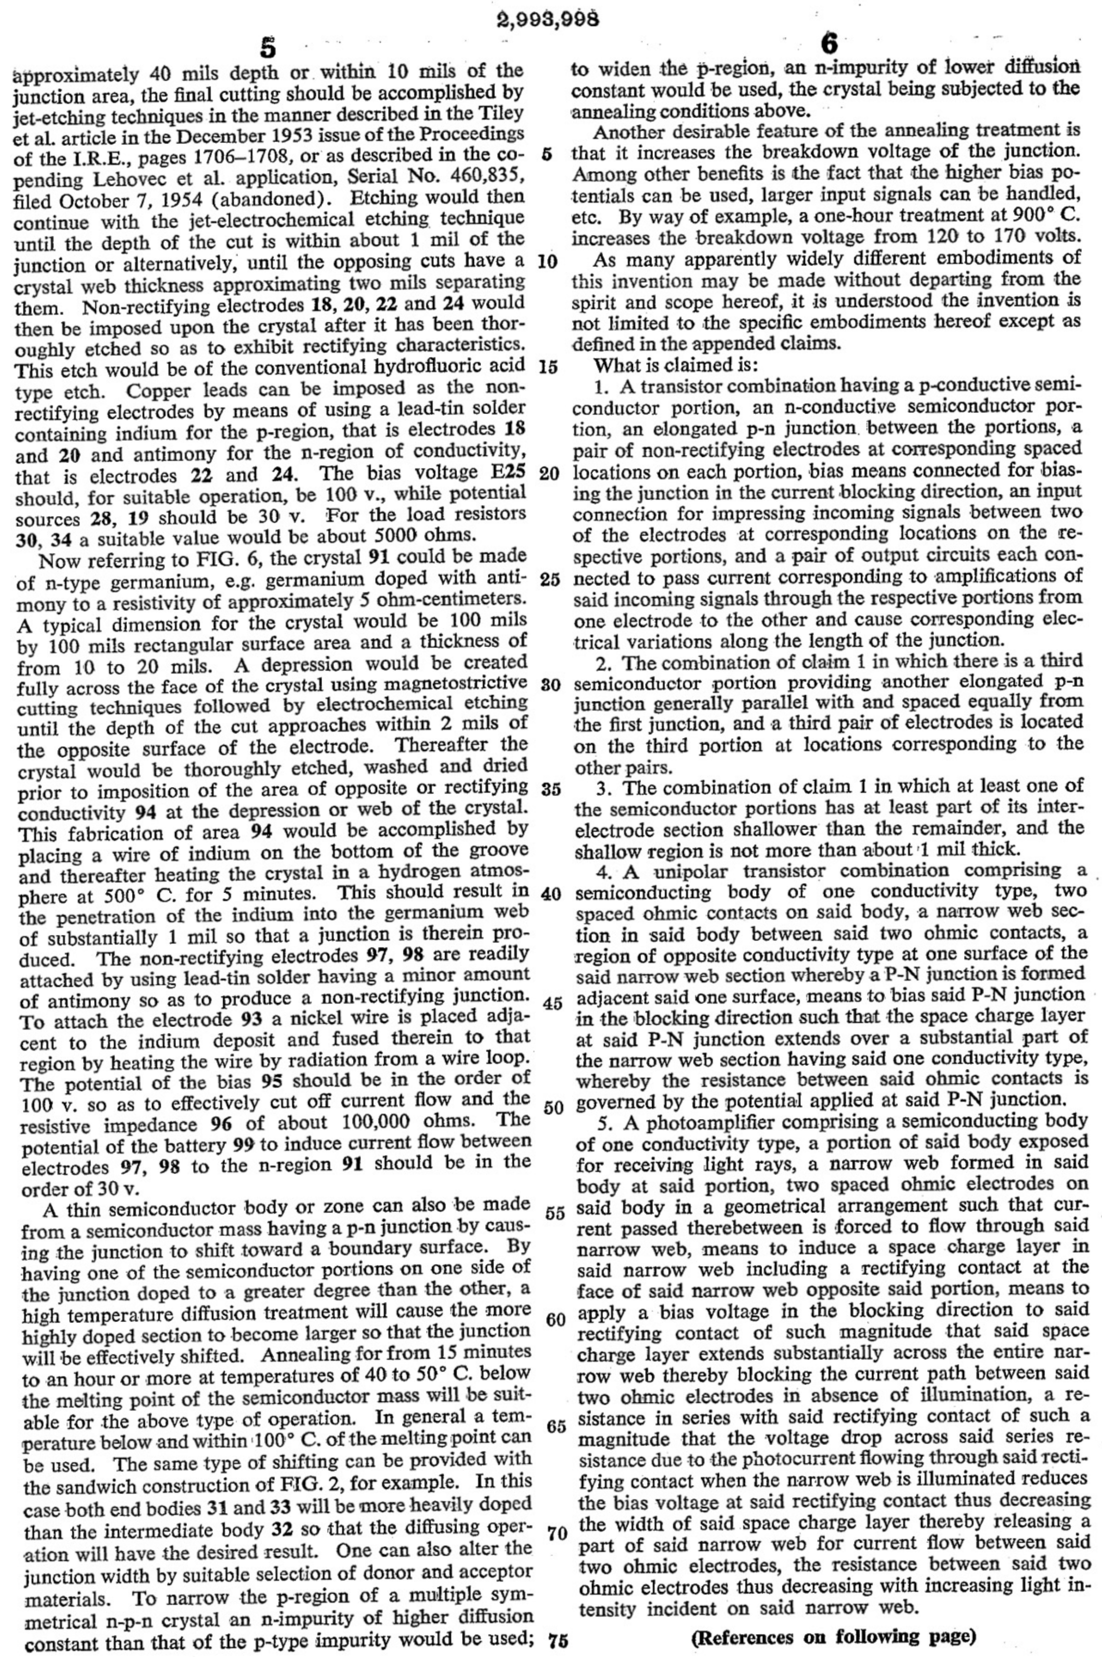
Instead of applying the bias to the same electrodes by which the input signals are impressed, other electrodes can be used. In the construction of FIG. 1, for example, bias can be provided between electrodes **18** and **22**, whereas the input signals can be applied between electrodes **20** and **24**. A similar arrangement can be used in the construction of FIG. 2. Furthermore, the bias need not be applied between correspondingly located electrodes, and can be impressed between electrodes **18** and **24**, for example. The incoming signals can also be applied in this manner.

FIG. 6 shows a further form of unipolar transistor construction most useful as a photosensitive device in which the bulk of the crystal **91** is of one conductivity, e.g. n-type, however a diffused junction exists at the region of the depression. In the depression there is an electrode **93**, and at opposite edges of the crystal are non-rectifying electrodes **97, 98**. The electrode **93** and one of the other non-rectifying electrodes **97** are connected to a high impedance bias source shown as a resistive impedance **96** and a voltage source or battery **95**. When the body **91** of such material is exposed to incident light, current flows across the web between electrode **93** adjacent the irradiation site and the crystal **91**. This current flow reduces the bias imposed by the battery **95** through resistor **96**. Thus the space charge in body **91** adjacent to electrode **93** is reduced allowing greater flow of current in the channel between non-rectifying electrodes **97, 98**.

The voltage source **95** biases the electrode **97** in the current-blocking direction. With the impedance **96** relatively low as compared to the blocking impedance of the un-illuminated junction, the potential of source **95** is essentially entirely impressed across this junction **94**. When irradiation takes place, the impedance of the junction is sharply diminished so that the potential across the junction **94** is greatly lowered. The lowering of the potential across the blocking junction causes a corresponding amplified change in the current passed between output electrodes **97, 98** as a result of the decrease of the space charge region. The photoelectric output of the construction of FIG. 6 will accordingly be much higher than that conventionally obtained from present devices, and has a sensitivity to radiation which is remarkable.

Although it is to be fully understood that the following specific examples are representative of the best constructions known to us, they should not in any way limit the scope of the instant invention. Reference should now be made to the drawing of FIG. 1 wherein in its preparation one would take a rectangular slab of p-n junction crystal produced by surface melting techniques or other techniques known to the art, and properly dimension the crystal as follows: The crystal could be a cube of 100 mils in each dimension with the junction region substantially in the center of the plane of the cube. Such a crystal would be of germanium and have for the p-impurity indium and for the n-impurity antimony, with each region of conductivity having a resistivity in the order of 5 ohm-centimeters. As indicated above, such a crystal could be produced by any of the known techniques including the surface melting technique fully disclosed in the copending application of Lehovec et al., Serial No. 364,138, filed June 25, 1953 (abandoned). The depressions **16, 17** should be then imposed across the opposing faces of the crystal first by magnetostrictive cutting with an appropriate tool, which technique is fully disclosed in United States Patent No. 2,580,716. The width of this cut would be approximately 15 mils and extend with vertical sides down to the region adjacent to the junction. After the magnetostrictive cutting has produced a depression of

Figure B.142: Kurt Lehovec developed semiconductor devices for Germany during the war. After the war he was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits.



2,993,998

5

approximately 40 mils depth or within 10 mils of the junction area, the final cutting should be accomplished by jet-etching techniques in the manner described in the Tiley et al. article in the December 1953 issue of the Proceedings of the I.R.E., pages 1706–1708, or as described in the copending Lehovec et al. application, Serial No. 460,835, filed October 7, 1954 (abandoned). Etching would then continue with the jet-electrochemical etching technique until the depth of the cut is within about 1 mil of the junction or alternatively, until the opposing cuts have a crystal web thickness approximating two mils separating them. Non-rectifying electrodes **18**, **20**, **22** and **24** would then be imposed upon the crystal after it has been thoroughly etched so as to exhibit rectifying characteristics. This etch would be of the conventional hydrofluoric acid type etch. Copper leads can be imposed as the non-rectifying electrodes by means of using a lead-tin solder containing indium for the p-region, that is electrodes **18** and **20** and antimony for the n-region of conductivity, that is electrodes **22** and **24**. The bias voltage E**25** should, for suitable operation, be 100 v., while potential sources **28**, **19** should be 30 v. For the load resistors **30**, **34** a suitable value would be about 5000 ohms.

Now referring to FIG. 6, the crystal **91** could be made of n-type germanium, e.g. germanium doped with antimony to a resistivity of approximately 5 ohm-centimeters. A typical dimension for the crystal would be 100 mils by 100 mils rectangular surface area and a thickness of from 10 to 20 mils. A depression would be created fully across the face of the crystal using magnetostrictive cutting techniques followed by electrochemical etching until the depth of the cut approaches within 2 mils of the opposite surface of the electrode. Thereafter the crystal would be thoroughly etched, washed and dried prior to imposition of the area of opposite or rectifying conductivity **94** at the depression or web of the crystal. This fabrication of area **94** would be accomplished by placing a wire of indium on the bottom of the groove and thereafter heating the crystal in a hydrogen atmosphere at 500° C. for 5 minutes. This should result in the penetration of the indium into the germanium web of substantially 1 mil so that a junction is therein produced. The non-rectifying electrodes **97**, **98** are readily attached by using lead-tin solder having a minor amount of antimony so as to produce a non-rectifying junction. To attach the electrode **93** a nickel wire is placed adjacent to the indium deposit and fused therein to that region by heating the wire by radiation from a wire loop. The potential of the bias **95** should be in the order of 100 v. so as to effectively cut off current flow and the resistive impedance **96** of about 100,000 ohms. The potential of the battery **99** to induce current flow between electrodes **97**, **98** to the n-region **91** should be in the order of 30 v.

A thin semiconductor body or zone can also be made from a semiconductor mass having a p-n junction by causing the junction to shift toward a boundary surface. By having one of the semiconductor portions on one side of the junction doped to a greater degree than the other, a high temperature diffusion treatment will cause the more highly doped section to become larger so that the junction will be effectively shifted. Annealing for from 15 minutes to an hour or more at temperatures of 40 to 50° C. below the melting point of the semiconductor mass will be suitable for the above type of operation. In general a temperature below and within 100° C. of the melting point can be used. The same type of shifting can be provided with the sandwich construction of FIG. 2, for example. In this case both end bodies **31** and **33** will be more heavily doped than the intermediate body **32** so that the diffusing operation will have the desired result. One can also alter the junction width by suitable selection of donor and acceptor materials. To narrow the p-region of a multiple symmetrical n-p-n crystal an n-impurity of higher diffusion constant than that of the p-type impurity would be used;

6

to widen the p-region, an n-impurity of lower diffusion constant would be used, the crystal being subjected to the annealing conditions above.

Another desirable feature of the annealing treatment is that it increases the breakdown voltage of the junction. Among other benefits is the fact that the higher bias potentials can be used, larger input signals can be handled, etc. By way of example, a one-hour treatment at 900° C. increases the breakdown voltage from 120 to 170 volts.

As many apparently widely different embodiments of this invention may be made without departing from the spirit and scope hereof, it is understood the invention is not limited to the specific embodiments hereof except as defined in the appended claims.

What is claimed is:

1. A transistor combination having a p-conductive semiconductor portion, an n-conductive semiconductor portion, an elongated p-n junction between the portions, a pair of non-rectifying electrodes at corresponding spaced locations on each portion, bias means connected for biasing the junction in the current blocking direction, an input connection for impressing incoming signals between two of the electrodes at corresponding locations on the respective portions, and a pair of output circuits each connected to pass current corresponding to amplifications of said incoming signals through the respective portions from one electrode to the other and cause corresponding electrical variations along the length of the junction.

2. The combination of claim 1 in which there is a third semiconductor portion providing another elongated p-n junction generally parallel with and spaced equally from the first junction, and a third pair of electrodes is located on the third portion at locations corresponding to the other pairs.

3. The combination of claim 1 in which at least one of the semiconductor portions has at least part of its inter-electrode section shallower than the remainder, and the shallow region is not more than about 1 mil thick.

4. A unipolar transistor combination comprising a semiconducting body of one conductivity type, two spaced ohmic contacts on said body, a narrow web section in said body between said two ohmic contacts, a region of opposite conductivity type at one surface of the said narrow web section whereby a P-N junction is formed adjacent said one surface, means to bias said P-N junction in the blocking direction such that the space charge layer at said P-N junction extends over a substantial part of the narrow web section having said one conductivity type, whereby the resistance between said ohmic contacts is governed by the potential applied at said P-N junction.

5. A photoamplifier comprising a semiconducting body of one conductivity type, a portion of said body exposed for receiving light rays, a narrow web formed in said body at said portion, two spaced ohmic electrodes on said body in a geometrical arrangement such that current passed therebetween is forced to flow through said narrow web, means to induce a space charge layer in said narrow web including a rectifying contact at the face of said narrow web opposite said portion, means to apply a bias voltage in the blocking direction to said rectifying contact of such magnitude that said space charge layer extends substantially across the entire narrow web thereby blocking the current path between said two ohmic electrodes in absence of illumination, a resistance in series with said rectifying contact of such a magnitude that the voltage drop across said series resistance due to the photocurrent flowing through said rectifying contact when the narrow web is illuminated reduces the bias voltage at said rectifying contact thus decreasing the width of said space charge layer thereby releasing a part of said narrow web for current flow between said two ohmic electrodes, the resistance between said two ohmic electrodes thus decreasing with increasing light intensity incident on said narrow web.

MULTIPLE JUNCTION TRANSISTOR UNIT

Kurt Lehovec, Williamstown, Mass., assignor to Sprague Electric Company, North Adams, Mass., a corporation of Massachusetts

Application June 17, 1955, Serial No. 516,180

4 Claims. (Cl. 250—211)

This invention relates to semiconductor signal translating devices and more particularly to bi-stable circuits which include a novel semiconductive device.

Bi-stable circuits that include transistors of the junction type form the subject matter of United States Patent No. 2,655,609, issued October 13, 1953. This patent is concerned with the use of a pair of symmetrical multiple junction transistors associated so as to constitute a composite circuit element having novel advantageous characteristics as a switching structure readily transferable from the open circuit to the closed state upon application of a voltage of prescribed amplitude between the input terminals. The individual transistors used have to be protected carefully against the influence of the operational enviroment by hermetic sealing. This requirement of hermetic sealing necessitates a housing requiring a substantially greater volume than that volume demanded by the physical configuration of the transistor itself. Further, to be satisfactory, the operational characteristics of the two transistors must be carefully matched for incorporation into the circuit.

One general object of this invention is therefore to produce multiple junction semiconductor crystals suitable for bi-stable circuits. A more specific object of this invention is production of a fused junction by a novel process. Other objects will be apparent from the following paragraphs and appended drawings.

Briefly, the objects of this invention have been achieved by the production of a semiconductive crystal of the symmetrical multiple grown junction type which further has at least two fused junction regions integrated into one conductivity region of the multiple junction.

In a more limited sense, the objects of this invention have been achieved by the production of a signal translating device which comprises a semiconductive crystal of the symmetrical multiple grown junction type having at least two fused junctions with electrodes secured respectively to the intermediate section of said multiple grown junction, the two said fused junctions and the end regions of said multiple grown junction.

The invention and the other features noted above will be understood more clearly and fully from the detailed description with reference to the accompanying drawings in which:

Fig. 1 is a cross-sectional view of the grown and fused junction semiconductor element of the invention;

Fig. 2 is a diagram representing a circuit embodiment of utilizing the device of the invention;

Figs. 3, 4 and 5 depict other circuitry including both Zener diodes and the device of the invention;

Fig. 6 illustrates an amplifier circuit using the single transistor of the invention;

Fig. 7 pictures a cross-sectional view of a light responsive signal translating device; and

Fig. 8 is a cross-sectional view of an apparatus for imposing the fused junction regions onto the surface of the multiple grown junction crystal.

Referring now to the drawings, Fig. 1 shows a cross-section of a semiconductive structure which replaces two of the transistors previously required for bi-stable circuits. The crystal 10 is monocrystalline and of germanium or silicon appropriately doped with impurities so as to effect symmertical multiple junctions of the n-p-n or p-n-p types. Herein is shown a grown n-p-n crystal having the n-regions designated 12 and 14 and the p intermediate region as 16. At one end of the crystal there are imposed two regions 18 and 20 of p conductivity produced as fused junctions. It is thus seen that there is in one crystal an n-p-n body which in turn finds one of the regions of n conductivity serving as the intermediate conductivity region for a p-n-p junction crystal. Appropriate non-rectifying electrodes 22, 24, 26, 28 and 30 are attached to the crystal shown in Fig. 1. For best operation the crystal 10 has surface depressions in which the fused junctions are produced so as to limit the thickness of the intermediate n region. For certain applications it is not necessary to have the non-rectifying electrode 26 present.

In Fig. 2 which shows an elementary circuit application of the device of the invention the source 32, poled as shown in the drawing, is connected between the terminals 34 and 36 of the composite crystalline body. The terminals 34 and 36 may be, for example, the cross points in telephone switching systems. The polarity of the source 32 is such that at least one reversed biased junction is included in every current path that can be traced between the terminals 34 and 36 through the composite multiple junction crystal 10. Thus, as shown, the junctions J–2 and J–4 are biased in the reverse or high resistance direction, at least one of which junctions is included in any current path through the combination. The operating state with such a polarity is thus the high impedance or low current condition. Upon increase of the voltage between the terminals 34 and 36 the currents passed by the reversely biased junctions J–2 and J–4 will increase changing the bias across J–1 and J–3 which is a function of the current flow through resistors 38 and 40. At a certain potential the circuit will change to a high current or conduction condition which state obtains when the resistances of the crystal approach those of resistors 38 and 40. Thus the circuit may be triggered from a substantially open circuit (low current) state to a closed circuit (high current) state by the application of voltage of a necessary magnitude between the terminals 34 and 36.

In certain applications it is desirable to determine the point at which the circuit will trigger at a present value. This is readily accomplished by modification of the circuit of Fig. 2 to that of Figs. 3, 4 and 5 by the utilization of a semiconductor junction diode 50, for example, germanium or silicon, which is connected in series with resistor 40 between the terminals 34 and 36. Therefore in Fig. 3, when the voltage between the terminals 34 and 36 rises to such a level as to establish the Zener voltage across the diode, the resulting large current which flows through both resistors 38 and 40 produces such biases on the respective emitters of the composite transistor element to transfer the condition from a low current to a high current level. The preparation of such Zener diodes is readily accomplished by surface melting of a crystal of given impurity, doping the melt with an impurity which produces a body of opposite conductivity and solidifying. The Zener voltage is a function of the conductivity of the crystal and can thus be fabricated for a given voltage of up to 100 volts or greater. In both Figs. 2 and 3, after the device is triggered to the high current or closed circuit conditions, it remains in that condition until the voltage between the terminals 34 and 36 is reduced to substantially 0. For ease of discussion the designation of the elements is common for Figs. 2, 3, 4 and 5. In

Figure B.146: Kurt Lehovec developed semiconductor devices for Germany during the war. After the war he was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits.

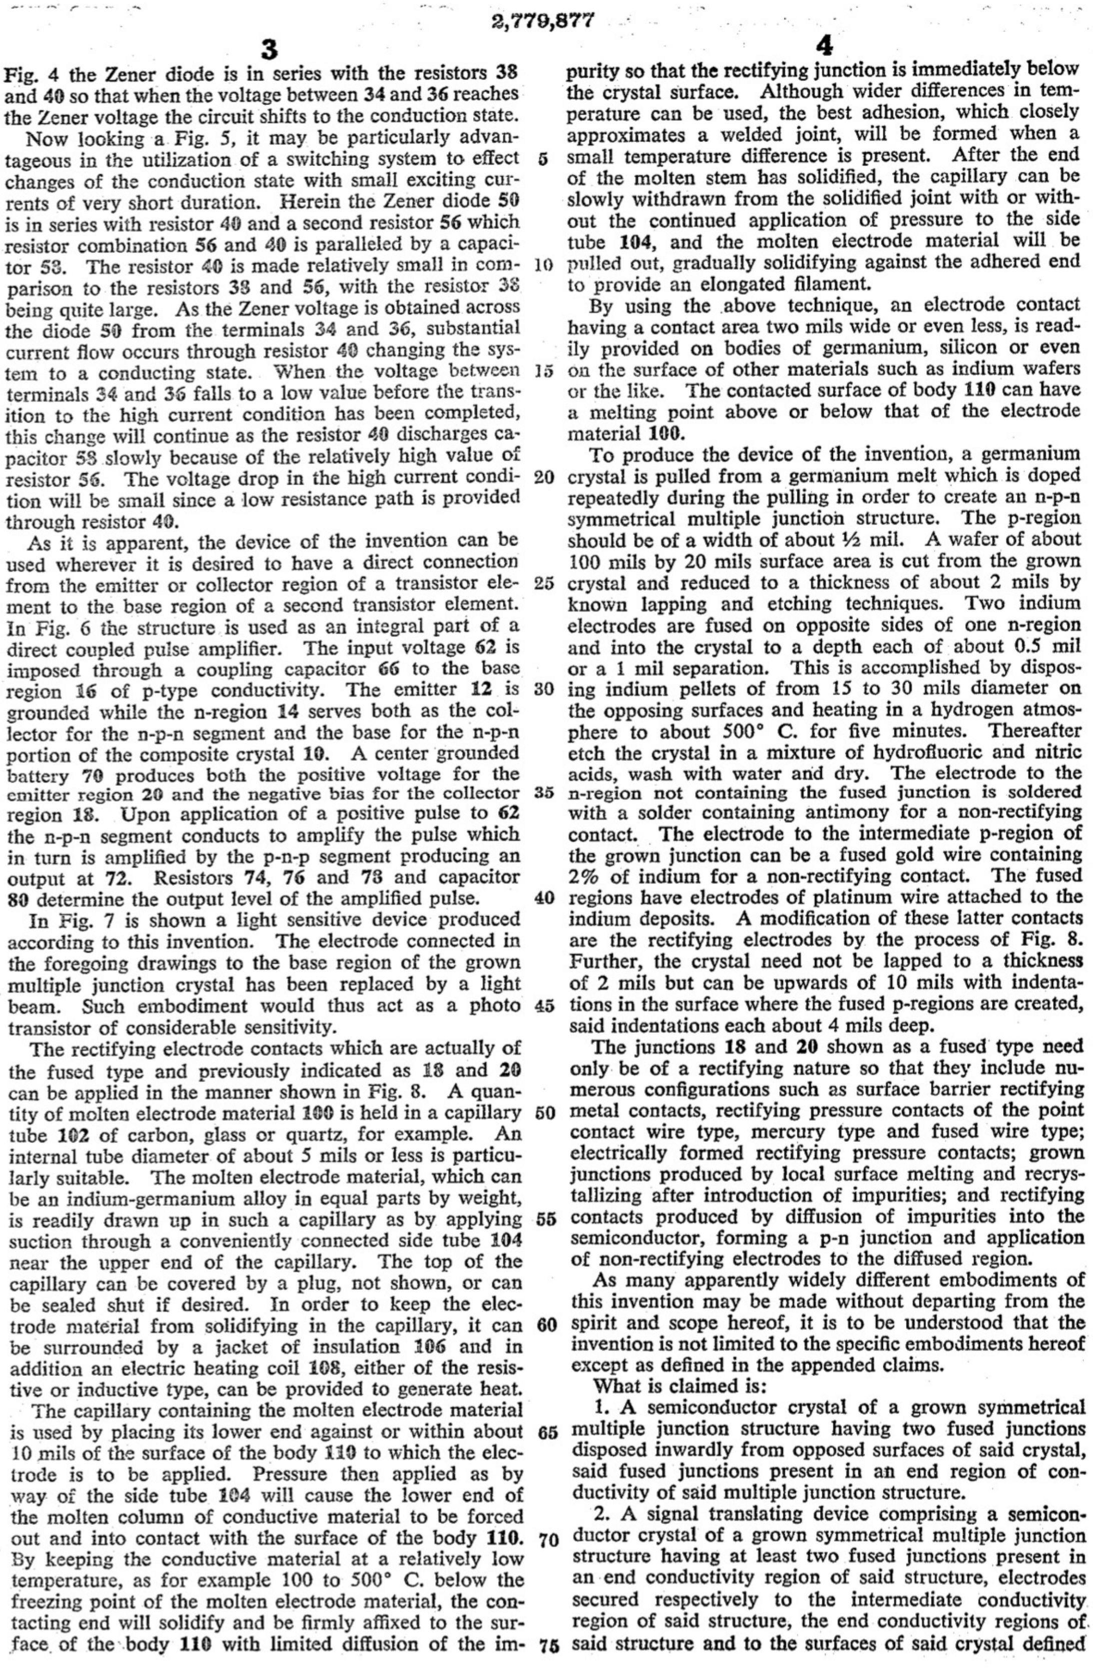

Fig. 4 the Zener diode is in series with the resistors **38** and **40** so that when the voltage between **34** and **36** reaches the Zener voltage the circuit shifts to the conduction state.

Now looking a Fig. 5, it may be particularly advantageous in the utilization of a switching system to effect changes of the conduction state with small exciting currents of very short duration. Herein the Zener diode **50** is in series with resistor **40** and a second resistor **56** which resistor combination **56** and **40** is paralleled by a capacitor **58**. The resistor **40** is made relatively small in comparison to the resistors **38** and **56**, with the resistor **38** being quite large. As the Zener voltage is obtained across the diode **50** from the terminals **34** and **36**, substantial current flow occurs through resistor **40** changing the system to a conducting state. When the voltage between terminals **34** and **36** falls to a low value before the transition to the high current condition has been completed, this change will continue as the resistor **40** discharges capacitor **58** slowly because of the relatively high value of resistor **56**. The voltage drop in the high current condition will be small since a low resistance path is provided through resistor **40**.

As it is apparent, the device of the invention can be used wherever it is desired to have a direct connection from the emitter or collector region of a transistor element to the base region of a second transistor element. In Fig. 6 the structure is used as an integral part of a direct coupled pulse amplifier. The input voltage **62** is imposed through a coupling capacitor **66** to the base region **16** of p-type conductivity. The emitter **12** is grounded while the n-region **14** serves both as the collector for the n-p-n segment and the base for the n-p-n portion of the composite crystal **10**. A center grounded battery **70** produces both the positive voltage for the emitter region **20** and the negative bias for the collector region **18**. Upon application of a positive pulse to **62** the n-p-n segment conducts to amplify the pulse which in turn is amplified by the p-n-p segment producing an output at **72**. Resistors **74**, **76** and **78** and capacitor **80** determine the output level of the amplified pulse.

In Fig. 7 is shown a light sensitive device produced according to this invention. The electrode connected in the foregoing drawings to the base region of the grown multiple junction crystal has been replaced by a light beam. Such embodiment would thus act as a photo transistor of considerable sensitivity.

The rectifying electrode contacts which are actually of the fused type and previously indicated as **18** and **20** can be applied in the manner shown in Fig. 8. A quantity of molten electrode material **100** is held in a capillary tube **102** of carbon, glass or quartz, for example. An internal tube diameter of about 5 mils or less is particularly suitable. The molten electrode material, which can be an indium-germanium alloy in equal parts by weight, is readily drawn up in such a capillary as by applying suction through a conveniently connected side tube **104** near the upper end of the capillary. The top of the capillary can be covered by a plug, not shown, or can be sealed shut if desired. In order to keep the electrode material from solidifying in the capillary, it can be surrounded by a jacket of insulation **106** and in addition an electric heating coil **108**, either of the resistive or inductive type, can be provided to generate heat.

The capillary containing the molten electrode material is used by placing its lower end against or within about 10 mils of the surface of the body **110** to which the electrode is to be applied. Pressure then applied as by way of the side tube **104** will cause the lower end of the molten column of conductive material to be forced out and into contact with the surface of the body **110**. By keeping the conductive material at a relatively low temperature, as for example 100 to 500° C. below the freezing point of the molten electrode material, the contacting end will solidify and be firmly affixed to the surface of the body **110** with limited diffusion of the impurity so that the rectifying junction is immediately below the crystal surface. Although wider differences in temperature can be used, the best adhesion, which closely approximates a welded joint, will be formed when a small temperature difference is present. After the end of the molten stem has solidified, the capillary can be slowly withdrawn from the solidified joint with or without the continued application of pressure to the side tube **104**, and the molten electrode material will be pulled out, gradually solidifying against the adhered end to provide an elongated filament.

By using the above technique, an electrode contact having a contact area two mils wide or even less, is readily provided on bodies of germanium, silicon or even on the surface of other materials such as indium wafers or the like. The contacted surface of body **110** can have a melting point above or below that of the electrode material **100**.

To produce the device of the invention, a germanium crystal is pulled from a germanium melt which is doped repeatedly during the pulling in order to create an n-p-n symmetrical multiple junction structure. The p-region should be of a width of about ½ mil. A wafer of about 100 mils by 20 mils surface area is cut from the grown crystal and reduced to a thickness of about 2 mils by known lapping and etching techniques. Two indium electrodes are fused on opposite sides of one n-region and into the crystal to a depth each of about 0.5 mil or a 1 mil separation. This is accomplished by disposing indium pellets of from 15 to 30 mils diameter on the opposing surfaces and heating in a hydrogen atmosphere to about 500° C. for five minutes. Thereafter etch the crystal in a mixture of hydrofluoric and nitric acids, wash with water and dry. The electrode to the n-region not containing the fused junction is soldered with a solder containing antimony for a non-rectifying contact. The electrode to the intermediate p-region of the grown junction can be a fused gold wire containing 2% of indium for a non-rectifying contact. The fused regions have electrodes of platinum wire attached to the indium deposits. A modification of these latter contacts are the rectifying electrodes by the process of Fig. 8. Further, the crystal need not be lapped to a thickness of 2 mils but can be upwards of 10 mils with indentations in the surface where the fused p-regions are created, said indentations each about 4 mils deep.

The junctions **18** and **20** shown as a fused type need only be of a rectifying nature so that they include numerous configurations such as surface barrier rectifying metal contacts, rectifying pressure contacts of the point contact wire type, mercury type and fused wire type; electrically formed rectifying pressure contacts; grown junctions produced by local surface melting and recrystallizing after introduction of impurities; and rectifying contacts produced by diffusion of impurities into the semiconductor, forming a p-n junction and application of non-rectifying electrodes to the diffused region.

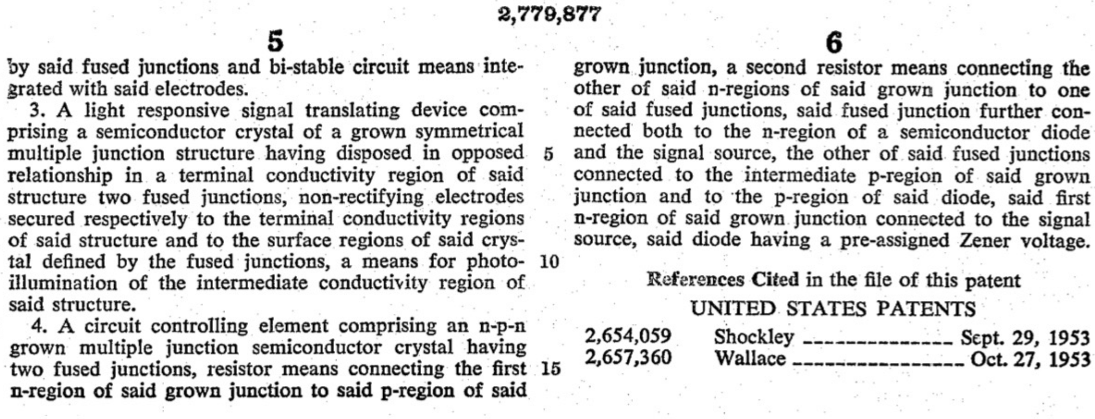
As many apparently widely different embodiments of this invention may be made without departing from the spirit and scope hereof, it is to be understood that the invention is not limited to the specific embodiments hereof except as defined in the appended claims.

What is claimed is:

1. A semiconductor crystal of a grown symmetrical multiple junction structure having two fused junctions disposed inwardly from opposed surfaces of said crystal, said fused junctions present in an end region of conductivity of said multiple junction structure.

2. A signal translating device comprising a semiconductor crystal of a grown symmetrical multiple junction structure having at least two fused junctions present in an end conductivity region of said structure, electrodes secured respectively to the intermediate conductivity region of said structure, the end conductivity regions of said structure and to the surfaces of said crystal defined

Figure B.147: Kurt Lehovec developed semiconductor devices for Germany during the war. After the war he was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits.



2,779,877

5

by said fused junctions and bi-stable circuit means integrated with said electrodes.

3. A light responsive signal translating device comprising a semiconductor crystal of a grown symmetrical multiple junction structure having disposed in opposed relationship in a terminal conductivity region of said structure two fused junctions, non-rectifying electrodes secured respectively to the terminal conductivity regions of said structure and to the surface regions of said crystal defined by the fused junctions, a means for photo-illumination of the intermediate conductivity region of said structure.

4. A circuit controlling element comprising an n-p-n grown multiple junction semiconductor crystal having two fused junctions, resistor means connecting the first n-region of said grown junction to said p-region of said grown junction, a second resistor means connecting the other of said n-regions of said grown junction to one of said fused junctions, said fused junction further connected both to the n-region of a semiconductor diode and the signal source, the other of said fused junctions connected to the intermediate p-region of said grown junction and to the p-region of said diode, said first n-region of said grown junction connected to the signal source, said diode having a pre-assigned Zener voltage.

MULTIPLE SEMICONDUCTOR ASSEMBLY

Kurt Lehovec, Williamstown, Mass., assignor to Sprague Electric Company, North Adams, Mass., a corporation of Massachusetts
Filed Apr. 22, 1959, Ser. No. 808,249
7 Claims. (Cl. 317—101)

This invention relates to a multiple semiconductor assembly, and more particularly to a plurality of semiconductive devices produced on a single semiconductor slice. Still more particularly, this invention relates to the micro-miniaturization of semiconductor assemblies by the preparation of several transistors and related devices on a single semiconductor slice, and the utilization of the resistive and capacitive properties of regions in that slice.

The present day miniaturization of electronic components has reached a state of art that may now be termed "micro-miniaturization," which may be defined as the assembly of a plurality of complementary components in an extremely small volume. Considerable activity has been expended in micro-miniaturizing circuits in which a plurality of transistors is employed. This micro-miniaturization activity has included the concept of direct coupling between stages of some particular types of transistors; e.g., surface-barrier and alloy-junction transistors have properties that permit their use in so-called common-emitter configurations in which the voltage at the collector of one transistor may be high enough to cause saturation at the base of the next transistor in the circuit. An article entitled, "Directly Coupled Transistor Circuits" by R. H. Beter, W. E. Bradley, R. B. Brown and M. Rubinoff, which was published in Electronics for June 1955, discloses the concept of employing a common-emitter transistor amplifier having more than one base connected to a single collector. Others in the art have suggested processes for producing a plurality of p-n junctions in a single semiconductor body; e.g., G. K. Teal U.S. Patent 2,727,840 and R. N. Hall U.S. Patent 2,822,308. However, great difficulty has been experienced in reaching the objective of a generally acceptable multi-transistor assembly on a single semiconductor body, because transistors so-produced have been electrically connected through the semiconductor slice. For example, in transistors of the alloy-junction type wherein the semiconductor slice of homogeneous impurity concentration represents the base of the transistor, all transistors in a multi-transistor assembly are connected to a common base, which is not a desirable configuration for many circuit applications.

A further example of the restricted nature of prior art multi-transistor assemblies is found in my U. S. Patent 2,779,877 issued January 29, 1957, which discloses and claims a signal translating device comprising a semiconductive crystal of the symmetrical grown junction type having two fused junctions disposed inwardly from opposed surfaces of the crystal.

It is an object of this invention to overcome these and other deficiencies of the prior art.

It is a further object of this invention to produce an assembly having a plurality of semiconductive components on a single semiconductor slice, and to provide a sufficient degree of electrical insulation between these semiconductive components through the semiconductor slice so as to permit a circuit designer to have substantial freedom in the interconnection of the components.

It is a still further object of this invention to produce an assembly having a plurality of transistors together with other components such as capacitors, resistors and diodes on a single semiconductor slice.

These and other objects of this invention will become more apparent upon consideration of the following detailed description when read in conjunction with the accompanying drawing, wherein:

FIGURE 1 is a diagrammatic perspective view of a multiple semiconductor assembly constructed in accordance with this invention, with electrical circuit wiring attached thereto to accomplish the circuit shown in FIGURE 3;

FIGURE 2 is a diagrammatic cross-section of the multiple semiconductor assembly taken along line 2—2 in FIGURE 1; in order to establish a clearer picture of the electrical interconnection of the various semiconductive components, FIGURE 2 is not a true cross-section of FIGURE 1, in that the contacts at the front surface of the assembly of FIGURE 1 have been shown again on the diagrammatic cross-section of FIGURE 2, although it should be understood that these contacts are not in the plane 2—2 of FIGURE 1;

FIGURE 3 is a schematic diagram of a chain of direct coupled amplifiers which may be assembled on a single semiconductor slice of the configuration shown in FIGURE 1 in accordance with this invention;

FIGURE 4 is a diagrammatic cross-sectional view through a multiple region semiconducting slice such as may be used in the construction of another embodiment of the multiple semiconductor assemblies according to this invention; and

FIGURE 5 is a diagrammatic plan view of the multiple region semiconductor slice of FIGURE 4.

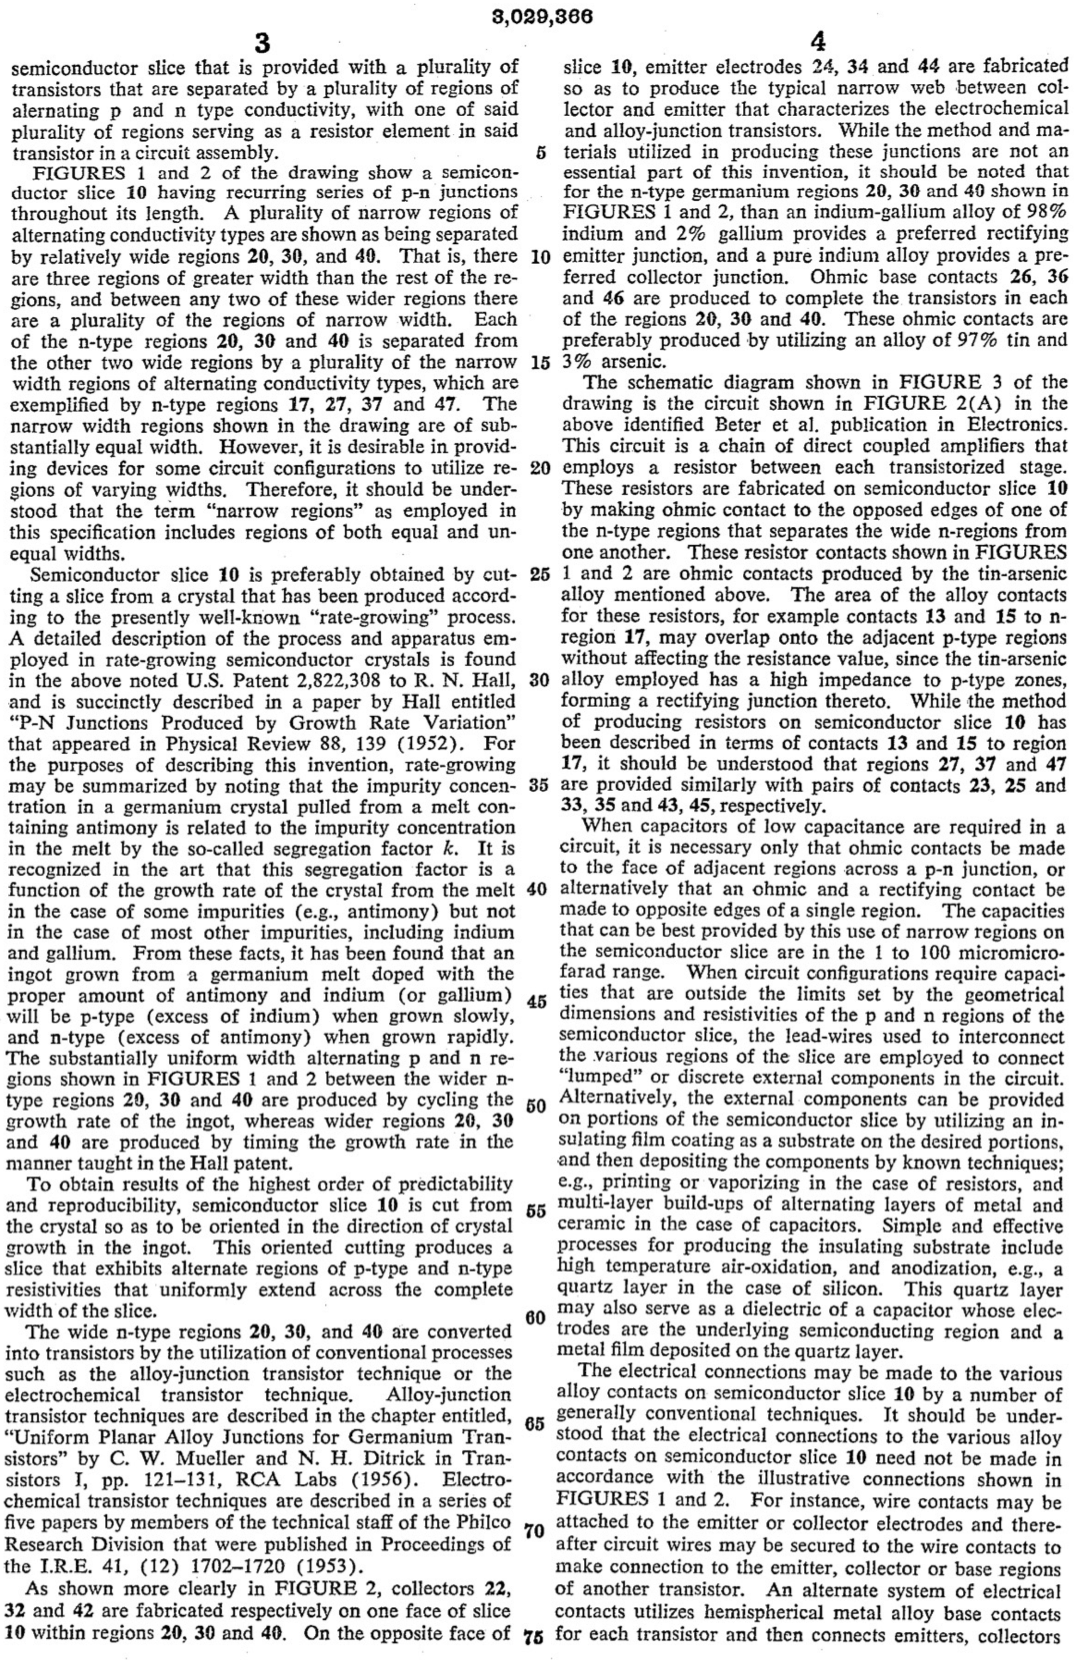
In general, the objects of this invention are attained by a multiple semiconductor assembly in which a plurality of semiconductor components are prepared on the same semiconductor slice in such a manner as to ensure electrical separation of the terminals of the individual semiconducting components. Since these semiconducting components will be transistors in many cases, the following description will be directed specifically to transistors although the concept of the invention applies also to other components, such as capacitors, resistors and diodes.

More particularly the objects of this invention are attained by utilizing a semiconductor slice having a series of p-n junctions that are so constructed and arranged that a transistor may be produced on each of a plurality of regions that are separated from one another by at least one additional p-n junction.

It is well known that a p-n junction has a high impedance to electric current, particularly if biased in the so-called "blocking direction," or with no bias applied. Therefore, any desired degree of electric insulation between two components assembled on the same slice can be achieved by having a sufficiently large number of p-n junctions in series between the two semiconducting regions on which said components are assembled. For most circuits, one to three p-n junctions will be sufficient to achieve the desired degree of insulation. These p-n junctions may be placed quite closely to each other. However, it is often required that they are placed sufficiently far apart from each other that the multiple p-n junction structure used for electric insulation should not act as an active semiconducting element such as a transistor or a four-layer npnp diode. In order to assure this condition, it is required that the region between two junctions is wider than a small multiple of the diffusion length of the minority carriers in said region. The diffusion length is the square root of the diffusion constant multiplied by the lifetime of these minority carriers. For instance, assuming a diffusion constant of 40 cm.^{2} per second and a lifetime of 1 microsecond, a diffusion length of 60×10^{-4} cm. or approximately 2 mils results, and a separation of 4 mils between the two junctions will be sufficient to avoid any appreciable interaction by carrier injection between the two junctions delineating said region.

In a restricted form of this invention, the objects are attained by a multiple transistor assembly comprising a

Figure B.150: Kurt Lehovec developed semiconductor devices for Germany during the war. After the war he was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits.



3,029,366

3

semiconductor slice that is provided with a plurality of transistors that are separated by a plurality of regions of alternating p and n type conductivity, with one of said plurality of regions serving as a resistor element in said transistor in a circuit assembly.

FIGURES 1 and 2 of the drawing show a semiconductor slice **10** having recurring series of p-n junctions throughout its length. A plurality of narrow regions of alternating conductivity types are shown as being separated by relatively wide regions **20, 30,** and **40.** That is, there are three regions of greater width than the rest of the regions, and between any two of these wider regions there are a plurality of the regions of narrow width. Each of the n-type regions **20, 30** and **40** is separated from the other two wide regions by a plurality of the narrow width regions of alternating conductivity types, which are exemplified by n-type regions **17, 27, 37** and **47.** The narrow width regions shown in the drawing are of substantially equal width. However, it is desirable in providing devices for some circuit configurations to utilize regions of varying widths. Therefore, it should be understood that the term "narrow regions" as employed in this specification includes regions of both equal and unequal widths.

Semiconductor slice **10** is preferably obtained by cutting a slice from a crystal that has been produced according to the presently well-known "rate-growing" process. A detailed description of the process and apparatus employed in rate-growing semiconductor crystals is found in the above noted U.S. Patent 2,822,308 to R. N. Hall, and is succinctly described in a paper by Hall entitled "P-N Junctions Produced by Growth Rate Variation" that appeared in Physical Review 88, 139 (1952). For the purposes of describing this invention, rate-growing may be summarized by noting that the impurity concentration in a germanium crystal pulled from a melt containing antimony is related to the impurity concentration in the melt by the so-called segregation factor *k*. It is recognized in the art that this segregation factor is a function of the growth rate of the crystal from the melt in the case of some impurities (e.g., antimony) but not in the case of most other impurities, including indium and gallium. From these facts, it has been found that an ingot grown from a germanium melt doped with the proper amount of antimony and indium (or gallium) will be p-type (excess of indium) when grown slowly, and n-type (excess of antimony) when grown rapidly. The substantially uniform width alternating p and n regions shown in FIGURES 1 and 2 between the wider n-type regions **20, 30** and **40** are produced by cycling the growth rate of the ingot, whereas wider regions **20, 30** and **40** are produced by timing the growth rate in the manner taught in the Hall patent.

To obtain results of the highest order of predictability and reproducibility, semiconductor slice **10** is cut from the crystal so as to be oriented in the direction of crystal growth in the ingot. This oriented cutting produces a slice that exhibits alternate regions of p-type and n-type resistivities that uniformly extend across the complete width of the slice.

The wide n-type regions **20, 30,** and **40** are converted into transistors by the utilization of conventional processes such as the alloy-junction transistor technique or the electrochemical transistor technique. Alloy-junction transistor techniques are described in the chapter entitled, "Uniform Planar Alloy Junctions for Germanium Transistors" by C. W. Mueller and N. H. Ditrick in Transistors I, pp. 121–131, RCA Labs (1956). Electrochemical transistor techniques are described in a series of five papers by members of the technical staff of the Philco Research Division that were published in Proceedings of the I.R.E. 41, (12) 1702–1720 (1953).

As shown more clearly in FIGURE 2, collectors **22, 32** and **42** are fabricated respectively on one face of slice **10** within regions **20, 30** and **40.** On the opposite face of

4

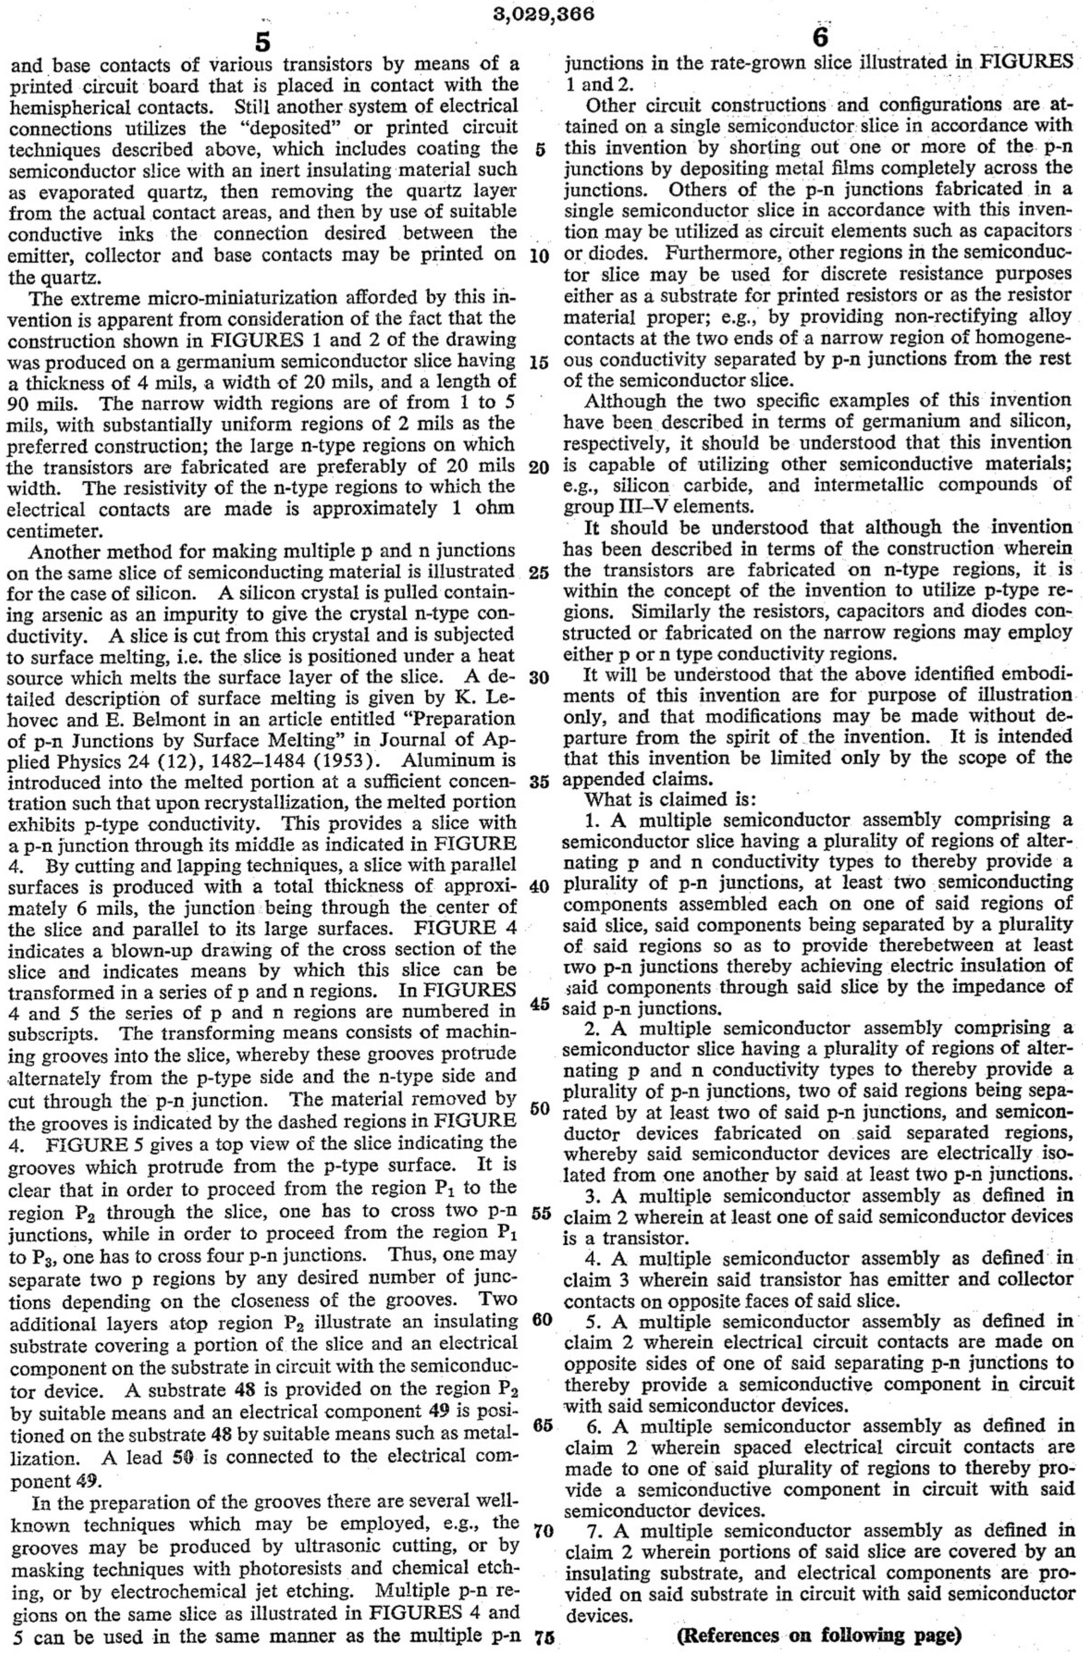
slice **10,** emitter electrodes **24, 34** and **44** are fabricated so as to produce the typical narrow web between collector and emitter that characterizes the electrochemical and alloy-junction transistors. While the method and materials utilized in producing these junctions are not an essential part of this invention, it should be noted that for the n-type germanium regions **20, 30** and **40** shown in FIGURES 1 and 2, than an indium-gallium alloy of 98% indium and 2% gallium provides a preferred rectifying emitter junction, and a pure indium alloy provides a preferred collector junction. Ohmic base contacts **26, 36** and **46** are produced to complete the transistors in each of the regions **20, 30** and **40.** These ohmic contacts are preferably produced by utilizing an alloy of 97% tin and 3% arsenic.

The schematic diagram shown in FIGURE 3 of the drawing is the circuit shown in FIGURE 2(A) in the above identified Beter et al. publication in Electronics. This circuit is a chain of direct coupled amplifiers that employs a resistor between each transistorized stage. These resistors are fabricated on semiconductor slice **10** by making ohmic contact to the opposed edges of one of the n-type regions that separates the wide n-regions from one another. These resistor contacts shown in FIGURES 1 and 2 are ohmic contacts produced by the tin-arsenic alloy mentioned above. The area of the alloy contacts for these resistors, for example contacts **13** and **15** to n-region **17,** may overlap onto the adjacent p-type regions without affecting the resistance value, since the tin-arsenic alloy employed has a high impedance to p-type zones, forming a rectifying junction thereto. While the method of producing resistors on semiconductor slice **10** has been described in terms of contacts **13** and **15** to region **17,** it should be understood that regions **27, 37** and **47** are provided similarly with pairs of contacts **23, 25** and **33, 35** and **43, 45,** respectively.

When capacitors of low capacitance are required in a circuit, it is necessary only that ohmic contacts be made to the face of adjacent regions across a p-n junction, or alternatively that an ohmic and a rectifying contact be made to opposite edges of a single region. The capacities that can be best provided by this use of narrow regions on the semiconductor slice are in the 1 to 100 micromicrofarad range. When circuit configurations require capacities that are outside the limits set by the geometrical dimensions and resistivities of the p and n regions of the semiconductor slice, the lead-wires used to interconnect the various regions of the slice are employed to connect "lumped" or discrete external components in the circuit. Alternatively, the external components can be provided on portions of the semiconductor slice by utilizing an insulating film coating as a substrate on the desired portions, and then depositing the components by known techniques; e.g., printing or vaporizing in the case of resistors, and multi-layer build-ups of alternating layers of metal and ceramic in the case of capacitors. Simple and effective processes for producing the insulating substrate include high temperature air-oxidation, and anodization, e.g., a quartz layer in the case of silicon. This quartz layer may also serve as a dielectric of a capacitor whose electrodes are the underlying semiconducting region and a metal film deposited on the quartz layer.

The electrical connections may be made to the various alloy contacts on semiconductor slice **10** by a number of generally conventional techniques. It should be understood that the electrical connections to the various alloy contacts on semiconductor slice **10** need not be made in accordance with the illustrative connections shown in FIGURES 1 and 2. For instance, wire contacts may be attached to the emitter or collector electrodes and thereafter circuit wires may be secured to the wire contacts to make connection to the emitter, collector or base regions of another transistor. An alternate system of electrical contacts utilizes hemispherical metal alloy base contacts for each transistor and then connects emitters, collectors

Figure B.151: Kurt Lehovec developed semiconductor devices for Germany during the war. After the war he was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits.



and base contacts of various transistors by means of a printed circuit board that is placed in contact with the hemispherical contacts. Still another system of electrical connections utilizes the "deposited" or printed circuit techniques described above, which includes coating the semiconductor slice with an inert insulating material such as evaporated quartz, then removing the quartz layer from the actual contact areas, and then by use of suitable conductive inks the connection desired between the emitter, collector and base contacts may be printed on the quartz.

The extreme micro-miniaturization afforded by this invention is apparent from consideration of the fact that the construction shown in FIGURES 1 and 2 of the drawing was produced on a germanium semiconductor slice having a thickness of 4 mils, a width of 20 mils, and a length of 90 mils. The narrow width regions are of from 1 to 5 mils, with substantially uniform regions of 2 mils as the preferred construction; the large n-type regions on which the transistors are fabricated are preferably of 20 mils width. The resistivity of the n-type regions to which the electrical contacts are made is approximately 1 ohm centimeter.

Another method for making multiple p and n junctions on the same slice of semiconducting material is illustrated for the case of silicon. A silicon crystal is pulled containing arsenic as an impurity to give the crystal n-type conductivity. A slice is cut from this crystal and is subjected to surface melting, i.e. the slice is positioned under a heat source which melts the surface layer of the slice. A detailed description of surface melting is given by K. Lehovec and E. Belmont in an article entitled "Preparation of p-n Junctions by Surface Melting" in Journal of Applied Physics 24 (12), 1482–1484 (1953). Aluminum is introduced into the melted portion at a sufficient concentration such that upon recrystallization, the melted portion exhibits p-type conductivity. This provides a slice with a p-n junction through its middle as indicated in FIGURE 4. By cutting and lapping techniques, a slice with parallel surfaces is produced with a total thickness of approximately 6 mils, the junction being through the center of the slice and parallel to its large surfaces. FIGURE 4 indicates a blown-up drawing of the cross section of the slice and indicates means by which this slice can be transformed in a series of p and n regions. In FIGURES 4 and 5 the series of p and n regions are numbered in subscripts. The transforming means consists of machining grooves into the slice, whereby these grooves protrude alternately from the p-type side and the n-type side and cut through the p-n junction. The material removed by the grooves is indicated by the dashed regions in FIGURE 4. FIGURE 5 gives a top view of the slice indicating the grooves which protrude from the p-type surface. It is clear that in order to proceed from the region P_1 to the region P_2 through the slice, one has to cross two p-n junctions, while in order to proceed from the region P_1 to P_3, one has to cross four p-n junctions. Thus, one may separate two p regions by any desired number of junctions depending on the closeness of the grooves. Two additional layers atop region P_2 illustrate an insulating substrate covering a portion of the slice and an electrical component on the substrate in circuit with the semiconductor device. A substrate **48** is provided on the region P_2 by suitable means and an electrical component **49** is positioned on the substrate **48** by suitable means such as metallization. A lead **50** is connected to the electrical component **49**.

In the preparation of the grooves there are several well-known techniques which may be employed, e.g., the grooves may be produced by ultrasonic cutting, or by masking techniques with photoresists and chemical etching, or by electrochemical jet etching. Multiple p-n regions on the same slice as illustrated in FIGURES 4 and 5 can be used in the same manner as the multiple p-n junctions in the rate-grown slice illustrated in FIGURES 1 and 2.

Other circuit constructions and configurations are attained on a single semiconductor slice in accordance with this invention by shorting out one or more of the p-n junctions by depositing metal films completely across the junctions. Others of the p-n junctions fabricated in a single semiconductor slice in accordance with this invention may be utilized as circuit elements such as capacitors or diodes. Furthermore, other regions in the semiconductor slice may be used for discrete resistance purposes either as a substrate for printed resistors or as the resistor material proper; e.g., by providing non-rectifying alloy contacts at the two ends of a narrow region of homogeneous conductivity separated by p-n junctions from the rest of the semiconductor slice.

Although the two specific examples of this invention have been described in terms of germanium and silicon, respectively, it should be understood that this invention is capable of utilizing other semiconductive materials; e.g., silicon carbide, and intermetallic compounds of group III–V elements.

It should be understood that although the invention has been described in terms of the construction wherein the transistors are fabricated on n-type regions, it is within the concept of the invention to utilize p-type regions. Similarly the resistors, capacitors and diodes constructed or fabricated on the narrow regions may employ either p or n type conductivity regions.

It will be understood that the above identified embodiments of this invention are for purpose of illustration only, and that modifications may be made without departure from the spirit of the invention. It is intended that this invention be limited only by the scope of the appended claims.

What is claimed is:

1. A multiple semiconductor assembly comprising a semiconductor slice having a plurality of regions of alternating p and n conductivity types to thereby provide a plurality of p-n junctions, at least two semiconducting components assembled each on one of said regions of said slice, said components being separated by a plurality of said regions so as to provide therebetween at least two p-n junctions thereby achieving electric insulation of said components through said slice by the impedance of said p-n junctions.

2. A multiple semiconductor assembly comprising a semiconductor slice having a plurality of regions of alternating p and n conductivity types to thereby provide a plurality of p-n junctions, two of said regions being separated by at least two of said p-n junctions, and semiconductor devices fabricated on said separated regions, whereby said semiconductor devices are electrically isolated from one another by said at least two p-n junctions.

3. A multiple semiconductor assembly as defined in claim 2 wherein at least one of said semiconductor devices is a transistor.

4. A multiple semiconductor assembly as defined in claim 3 wherein said transistor has emitter and collector contacts on opposite faces of said slice.

5. A multiple semiconductor assembly as defined in claim 2 wherein electrical circuit contacts are made on opposite sides of one of said separating p-n junctions to thereby provide a semiconductive component in circuit with said semiconductor devices.

6. A multiple semiconductor assembly as defined in claim 2 wherein spaced electrical circuit contacts are made to one of said plurality of regions to thereby provide a semiconductive component in circuit with said semiconductor devices.

7. A multiple semiconductor assembly as defined in claim 2 wherein portions of said slice are covered by an insulating substrate, and electrical components are provided on said substrate in circuit with said semiconductor devices.

Die Störstellenkonzentration ist in der Basiszone eines üblichen Flächentransistors praktisch konstant, so daß dort kein elektrisches Feld herrscht. Die vom Emitter herkommenden Minoritätsladungsträger können also nur durch reine Diffusion zum Kollektor gelangen. Dieser Flächentransistor ist also ein »Diffusions-Transistor«. Die Anwendung desselben ist gegenüber derjenigen des Spitzentransistors durch die wesentlich niedriger liegende Frequenzgrenze beschränkt.

In der Patentanmeldung P 13 01 862.7-33 (deutsche Auslegeschrift 1 301 862) ist bereits ein Verfahren zum Herstellen eines Drifttransistors angegeben, das darin besteht, daß eine oder mehrere Störstellenarten in die Basiszone von der Emitterseite so eindiffundiert werden, daß die Störstellenkonzentration an der Emitterseite der Basiszone mindestens zehnmal größer als an der Kollektorseite der Basiszone ist. Es ist dort auch bereits hervorgehoben, daß es bei einem solchen Drifttransistor besonders vorteilhaft ist, die Störstellenkonzentration vom Emitter zum Kollektor monoton abklingend verlaufen zu lassen, wobei die Abnahme an der Emitterseite stärker ist als an der Kollektorseite, so daß der 2. Differentialquotient der Kurve der Störstellenkonzentration überwiegend positiv ist. Beispielsweise kann die Störstellenkonzentration etwa rein exponentiell abfallen. In der Baziszone herrscht dann wegen der räumlichen Konstanz der Fermischen Grenzenergie ein ungefähr konstantes elektrisches Feld, welches die Minderheitsträger zwangläufig zum Kollektor hintreibt. Dies hat zur Folge, daß die oberste Grenzfrequenz des Transistors ansteigt.

Die Erfindung betrifft einen Drifttransistor, bei dem das elektrische Feld in der Basiszone des Transistors erfindungsgemäß dadurch erzeugt wird, daß die Halbleitergrundsubstanz selbst ein nichtstöchiometrischer Mischkristall verschiedener Halbleitermaterialien mit verschiedenen Bandabständen ist, wobei sich die Zusammensetzung des Mischkristalls innerhalb der Basis derart ändert, daß die Bandbreite von der Emitter- zur Kollektorseite monoton abnimmt, während der Leitfähigkeitstyp unveränderlich bleibt. Auf diese Weise läßt sich ein noch höheres Driftgefälle und damit eine noch stärkere Verbesserung der Frequenzgrenze erzielen.

Gegebenenfalls kann zusätzlich zu der Bandbreitenvariation die Störstellenkonzentration des Halbleitermaterials vom Emitter zum Kollektor monoton abnehmen. Dabei ist zweckmäßig die Feldstärke, die durch das Zusammenwirken von Störstellen- und Bandbreitenvariation entsteht, möglichst homogen zu machen. Diese Maßnahmen können zu einer weiteren Steigerung des Driftgefälles und damit zu einer weiteren Verbesserung der Frequenzgrenze führen. Vorzugsweise verläuft die Variation der Bandbreite linear, während der Störstellengehalt konstant ist oder exponentiell verläuft.

Als miteinander zu kombinierende Halbleitersubstanzen kommen für die Erfindung alle die Halbleitermaterialien in Frage, die auch sonst für die Transistorherstellung geeignet sind, vorausgesetzt, daß die Symmetrie ihrer Kristallgitter dieselbe ist. Dies sind insbesondere die Halbleitersubstanzen der IV. Gruppe des periodischen Systems der Elemente, wie Germanium und Silizium, sowie die gemischten Halbleiter vom Typ $A_{III}B_{V}$. Und zwar kann man sowohl Halbleitermaterialien der IV. Gruppe untereinander, als auch einen oder mehrere Halbleitermaterialien der IV. Gruppe mit einem oder mehreren $A_{III}B_{V}$-Halbleitern, als auch mehrere $A_{III}B_{V}$-Halbleiter untereinander kombinieren.

Die Herstellung der erforderlichen dünnen Basisschichten mit inhomogener Zusammensetzung geschieht zweckmäßigerweise so, daß man eine geeignete Menge einer geeigneten flüssigen Mischung der Komponenten langsam von einer Seite her erstarren läßt. Dabei ändert sich die Zusammensetzung des erstarrten Kristalls stetig, beginnend mit der Halbleitersubstanz des höchsten Schmelzpunktes, die im ersten und im dritten Falle der obigen Kombinationsmöglichkeiten gleichzeitig die Halbleitersubstanz mit dem höchsten Bandabstand ist.

Vorzugsweise kann man diesen Schmelzprozeß so durchführen, daß man die niedrigschmelzende(n) Komponente(n) auf ein festes Kristallstück der höchstschmelzenden Komponente aufbringt und das Ganze so hoch erhitzt, daß erstere schmilzt bzw. schmelzen und eine geeignete Menge der letzteren auflöst bzw. auflösen, woraufhin man die Erstarrung wie oben beschrieben durchführt.

Der hochschmelzende Kristall und die niedrigschmelzende(n) Komponente(n) werden dabei zweckmäßigerweise in einander entgegengesetzter Richtung so vordotiert, so daß sich beim Erstarren sogleich der eine der beiden die Basiszone begrenzenden pn-Übergänge bildet.

Wir betrachten jetzt einmal näher den Fall eines nur zweikomponentigen Mischkristalls, wo die höchstschmelzende Komponente auch den höheren Bandabstand hat. Dann bildet der nach dem beschriebenen Verfahren zuerst entstehende pn-Übergang später den Emitter. Es ist dann zweckmäßig, zur Vordotierung des festen Kristalls einen Stoff mit sehr kleinem Verteilungskoeffizienten zu wählen, d. h. einen Stoff, der beim Erstarren bevorzugt in die flüssige Phase geht, während man die niedrigschmelzende Komponente zweckmäßigerweise mit einem Stoff mit einem möglichst großen Verteilungskoeffizienten, vorzugsweise einem Verteilungskoeffizienten > 1, vordotiert. Man erhält dann nämlich gleichzeitig beim Erstarren der Schmelze den gewünschten monotonen Abfall der (Netto-)Störstellenkonzentration. Wenn die Verteilungskoeffizienten der beiden Dotierungsstoffe sich hinreichend stark unterscheiden, überwiegt schließlich gegen Ende des Erstarrungsprozesses wieder die Störstellenart des Emitterkristalls, so daß auch der zweite die Basiszone begrenzende pn-Übergang, der Kollektorübergang, in demselben Vorgang entsteht. Durch Variation der Menge der zweiten Halbleiterkomponente und Variation der Fremdstoffgehalte lassen sich die physikalischen Parameter der so entstehenden Transistoren in weitem Bereich beeinflussen.

Im Falle einer Silizium-Germanium-Kombination eignen sich zur Dotierung des Emitterkristalls vorwiegend die Elemente der III. Gruppe des Periodensystems der Elemente wie Arsen oder Antimon, zur Dotierung des Germanium vorwiegend Bor und Aluminium. Dabei entstehen npn-Transistoren.

Ganz analoge Überlegungen gelten für mehrkomponentige Systeme für andere Halbleiterarten sowie für den Fall, daß die höherschmelzenden Komponenten den niedrigeren Bandabstand haben.

ABSTRACT OF THE DISCLOSURE

A means for controlling the oscillation mode in bulk negative conductivity semiconductor oscillators. By doping the semiconductor so that a resistivity gradient exists between the positive and negative electrodes with a higher resistivity at the positive electrode, the oscillator can be made to reliably function in the pure accumulation mode. If the resistivity gradient is in the opposite direction, operation will be in the dipole space charge mode. Alternatively the operating mode can be controlled by utilizing a negative electrode formed of a semiconductor material having a higher resistivity than the semiconductor material of the main body and having a positive mobility over the operating range of the oscillator device.

This invention relates in general to microwave oscillators utilizing semiconductors which exhibit bulk negative conductivity and more particularly to the use of resistivity gradients and heterojunction electrodes in bulk negative conductivity semiconductors for the purpose of mode control.

The phenomena of bulk negative conductivity (BNC) in semiconductors having a particular type of band structure which results in the semiconductor having a drift velocity v vs. electric field E dependence which contains a region of negative differential mobility $\mu=dv/dE<0$ or a bulk negative conductivity has finally been achieved. The utilization of BNC semiconductors as oscillators, frequency generators at microwave frequencies up to 100 and perhaps 1000 gc., which is an ultimate limit, is clearly forseeable. The present invention is concerned with basic improvements in such BNC semiconductors with a resultant improvement in efficiency and spectral purity of the microwave oscillations generated by a BNC semiconductor.

The following background information should help in clarifying the terminology involved in the phenomena of a BNC semiconductor and lead to a better understanding of the basic improvements taught by the present invention.

An illustrative graphical portrayal of a typical BNC semiconductor drift velocity v vs. applied electric field E dependence containing a region of bulk negative differential conductivity is shown in FIG. 1. The region between T and V where $\mu=dv/dE<0$ where μ=electron mobility typifies a BNC semiconductor. The negative differential mobility region occurs at applied electric fields above E_T and extends to E_V. The exact values of E_T and E_V will of course depend on the particular BNC semiconductor under consideration.

The rationale for the negative differential mobility region of the FIG. 1 plot can be seen from an examination of the generic energy band diagram of FIG. 2. This K-space diagram is particularly directed to n-type GaAs but is representative of the generic class of semiconductors falling within the teachings of the present invention. In brief, the conduction band structure of a BNC semiconductor will be a many valley type characterized in the following manner:

2

The semiconductor will be an n-type semiconductor body having a conduction band structure characterized by having satellite valleys which lie energetically higher than a central main valley, with the satellite valleys further characterized by a lower mobility (higher effective mass) than the mobility (lower effective mass) associated with the central main valley, and wherein the energy differential between the bottom of the satellite valleys and the bottom of the central main valley portions of the conduction band is smaller than the energy differential between the top of the valence band and the bottom of the central main valley of the conduction band and wherein the energy differential between the bottom of the satellite valleys and the bottom of the central main valley portion of the conduction band is greater than $2kT$ at the operating temperature where k=Boltzmann's constant and T=absolute temperature in degrees Kelvin of the semiconductor body or crystal temperature at the operating temperature.

It is to be noted that the generic band structure is obviously not to be restricted to any particular crystallographic axis such as the (100) axis which was chosen only to illustrate a particular example of the general case.

This type of semiconductor will, upon application of a D.C. bias voltage such that $V/w>E_T$ for any portion of the body where

V=bias voltage
w=semiconductor body width between source and drain electrodes and
E_T=threshold field;

generate traveling space charge domains which originate at the negative or source electrode and exit at the drain electrode. The exact natural frequency of any given BNC semiconductor will of course vary with the bias, load, material, etc., parameters. The generation of traveling space charge domains can be shown to occur for BNC semiconductor diodes characterized by the following relationship:

$$nw\gtrsim10^{12}/\text{cm.}^2$$

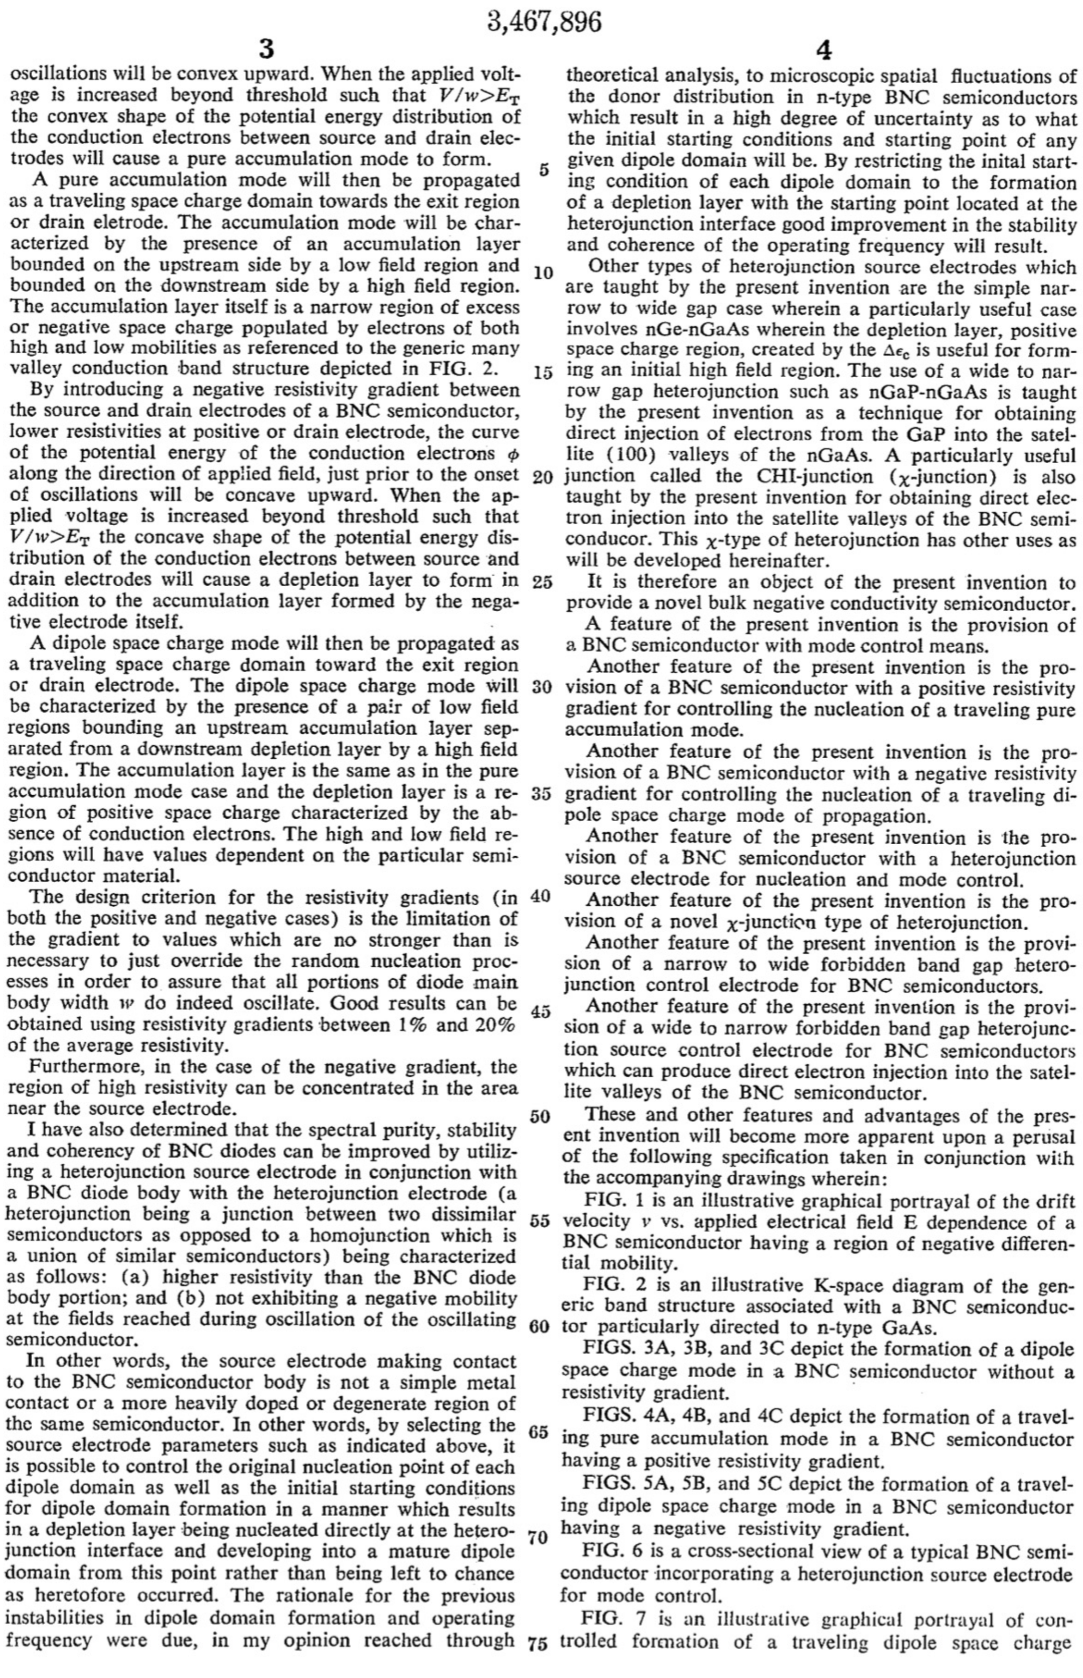
where n=conduction electron number density and
w=semiconductor body width or thickness in cm. between source and drain electrodes.

The generated frequency will in any case be approximately $f\approx10^7/w$. in Hz. or cycles/sec. with an upper limit around v_T/w and a lower limit around v_L/w at fields above E_T.

The spectral purity, coherence etc. of any given BNC semiconductor oscillator is dependent upon the particular type of traveling space charge domain being generated and the initial starting conditions. The observed rather erratic performance of BNC semiconductors with regard to poor coherence and spectral purity is fundamentally due to microscopic spatial fluctuations in the impurity distribution of the donor ions which results in instabilities in the nature of the initial starting conditions of the traveling space charge domains. By the utilization of resistivity gradients in the main body of the semiconductor between the source and drain electrodes it is possible not only to better control the point of origin of a given space charge domain but also to predetermine the particular type of domain which will be propagated. The resistivity gradients can be positive or negative between the source and drain electrodes and the particular shapes are preferably linear although stepped, non-linear and curved gradients would suffice.

By introducing a positive resistivity gradient between the source and drain electrodes of a BNC semiconductor, higher resistivities at positive or drain electrode, the curve of potential energy of the conduction electrons ϕ along the direction of applied field, just prior to the onset of

Figure B.160: Herbert Kroemer invented III-V semiconductor heterostructures in 1966.



oscillations will be convex upward. When the applied voltage is increased beyond threshold such that $V/w>E_T$ the convex shape of the potential energy distribution of the conduction electrons between source and drain electrodes will cause a pure accumulation mode to form.

A pure accumulation mode will then be propagated as a traveling space charge domain towards the exit region or drain eletrode. The accumulation mode will be characterized by the presence of an accumulation layer bounded on the upstream side by a low field region and bounded on the downstream side by a high field region. The accumulation layer itself is a narrow region of excess or negative space charge populated by electrons of both high and low mobilities as referenced to the generic many valley conduction band structure depicted in FIG. 2.

By introducing a negative resistivity gradient between the source and drain electrodes of a BNC semiconductor, lower resistivities at positive or drain electrode, the curve of the potential energy of the conduction electrons ϕ along the direction of applied field, just prior to the onset of oscillations will be concave upward. When the applied voltage is increased beyond threshold such that $V/w>E_T$ the concave shape of the potential energy distribution of the conduction electrons between source and drain electrodes will cause a depletion layer to form in addition to the accumulation layer formed by the negative electrode itself.

A dipole space charge mode will then be propagated as a traveling space charge domain toward the exit region or drain electrode. The dipole space charge mode will be characterized by the presence of a pair of low field regions bounding an upstream accumulation layer separated from a downstream depletion layer by a high field region. The accumulation layer is the same as in the pure accumulation mode case and the depletion layer is a region of positive space charge characterized by the absence of conduction electrons. The high and low field regions will have values dependent on the particular semiconductor material.

The design criterion for the resistivity gradients (in both the positive and negative cases) is the limitation of the gradient to values which are no stronger than is necessary to just override the random nucleation processes in order to assure that all portions of diode main body width w do indeed oscillate. Good results can be obtained using resistivity gradients between 1% and 20% of the average resistivity.

Furthermore, in the case of the negative gradient, the region of high resistivity can be concentrated in the area near the source electrode.

I have also determined that the spectral purity, stability and coherency of BNC diodes can be improved by utilizing a heterojunction source electrode in conjunction with a BNC diode body with the heterojunction electrode (a heterojunction being a junction between two dissimilar semiconductors as opposed to a homojunction which is a union of similar semiconductors) being characterized as follows: (a) higher resistivity than the BNC diode body portion; and (b) not exhibiting a negative mobility at the fields reached during oscillation of the oscillating semiconductor.

In other words, the source electrode making contact to the BNC semiconductor body is not a simple metal contact or a more heavily doped or degenerate region of the same semiconductor. In other words, by selecting the source electrode parameters such as indicated above, it is possible to control the original nucleation point of each dipole domain as well as the initial starting conditions for dipole domain formation in a manner which results in a depletion layer being nucleated directly at the heterojunction interface and developing into a mature dipole domain from this point rather than being left to chance as heretofore occurred. The rationale for the previous instabilities in dipole domain formation and operating frequency were due, in my opinion reached through theoretical analysis, to microscopic spatial fluctuations of the donor distribution in n-type BNC semiconductors which result in a high degree of uncertainty as to what the initial starting conditions and starting point of any given dipole domain will be. By restricting the inital starting condition of each dipole domain to the formation of a depletion layer with the starting point located at the heterojunction interface good improvement in the stability and coherence of the operating frequency will result.

Other types of heterojunction source electrodes which are taught by the present invention are the simple narrow to wide gap case wherein a particularly useful case involves nGe-nGaAs wherein the depletion layer, positive space charge region, created by the $\Delta\epsilon_c$ is useful for forming an initial high field region. The use of a wide to narrow gap heterojunction such as nGaP-nGaAs is taught by the present invention as a technique for obtaining direct injection of electrons from the GaP into the satellite (100) valleys of the nGaAs. A particularly useful junction called the CHI-junction (χ-junction) is also taught by the present invention for obtaining direct electron injection into the satellite valleys of the BNC semiconducor. This χ-type of heterojunction has other uses as will be developed hereinafter.

It is therefore an object of the present invention to provide a novel bulk negative conductivity semiconductor.

A feature of the present invention is the provision of a BNC semiconductor with mode control means.

Another feature of the present invention is the provision of a BNC semiconductor with a positive resistivity gradient for controlling the nucleation of a traveling pure accumulation mode.

Another feature of the present invention is the provision of a BNC semiconductor with a negative resistivity gradient for controlling the nucleation of a traveling dipole space charge mode of propagation.

Another feature of the present invention is the provision of a BNC semiconductor with a heterojunction source electrode for nucleation and mode control.

Another feature of the present invention is the provision of a novel χ-junction type of heterojunction.

Another feature of the present invention is the provision of a narrow to wide forbidden band gap heterojunction control electrode for BNC semiconductors.

Another feature of the present invention is the provision of a wide to narrow forbidden band gap heterojunction source control electrode for BNC semiconductors which can produce direct electron injection into the satellite valleys of the BNC semiconductor.

These and other features and advantages of the present invention will become more apparent upon a perusal of the following specification taken in conjunction with the accompanying drawings wherein:

FIG. 1 is an illustrative graphical portrayal of the drift velocity v vs. applied electrical field E dependence of a BNC semiconductor having a region of negative differential mobility.

FIG. 2 is an illustrative K-space diagram of the generic band structure associated with a BNC semiconductor particularly directed to n-type GaAs.

FIGS. 3A, 3B, and 3C depict the formation of a dipole space charge mode in a BNC semiconductor without a resistivity gradient.

FIGS. 4A, 4B, and 4C depict the formation of a traveling pure accumulation mode in a BNC semiconductor having a positive resistivity gradient.

FIGS. 5A, 5B, and 5C depict the formation of a traveling dipole space charge mode in a BNC semiconductor having a negative resistivity gradient.

FIG. 6 is a cross-sectional view of a typical BNC semiconductor incorporating a heterojunction source electrode for mode control.

FIG. 7 is an illustrative graphical portrayal of controlled formation of a traveling dipole space charge

domain type of mode in a BNC semiconductor incorporating a heterojunction control electrode.

FIGS. 8A, 8B, and 8C depict BNC diodes with heterojunction source control electrodes and additional auxiliary electrodes.

FIG. 9 illustrates a typical schematic circuit for a BNC semiconductor oscillator.

FIG. 10 depicts an illustrative portrayal of a nGe-nGaAs heterojunction source control electrode and simple energy band diagram.

FIG. 11 depicts an illustrative direct injection heterojunction source control electrode and BNC semiconductor.

FIGS. 12A and 12B depict a χ-junction for the case of nSi on nGaAs.

FIG. 13 depicts an illustrative graphical portrayal of the conceptual characteristics of a Si-GaAs χ-junction.

Turning now to FIG. 1 which shows the ν vs. E dependence for a BNC semiconductor, it is important to realize that the incidence of oscillations will occur as stated previously for field values $>E_T$.

The precise frequency of oscillation and drift velocity for any given type of mode will vary somewhat. For the pure accumulation type of mode the expected natural frequency would be around ν_T/w and for the fully formed dipole mode, if allowed to fully develop into a stable state, the expected natural frequency would be around ν_v/w. Of course, intermediate values are representative of intermediate stages.

The mechanism responsible for the generation of traveling space charge modes of propagation in BNC semiconductors is found in the band structure depicted in FIG. 2. The particular conduction band structure illustrated in FIG. 2 is directed to n-type GaAs which has been shown to fall within the generic classification set forth in the introductory remarks.

A few of the many semiconductors which exhibit this type of band structure are the following: n-type GaAs; n-type InP; n-type Cdte; n-type $Ga(As_{(1-x)}P_{(x)})$; with x <0.40.

Dopants can be selected from 6th column elements and such other well known dopants as Si, Ge, Sn for III–V semiconductors and e.g. Al for n-type CdTe.

The condition for oscillation in a traveling space charge mode regardless of type in BNC semiconductors can be expressed in a more simple manner as follows:

$$n_o w > 10^{12}/\text{cm.}^2$$

for thermal reasons the upper limit will be

$$n_o w < 10^{15}/\text{cm.}^2$$

where:

n_o=conduction or carrier electron number density without bias at the operating temperature

w=main body width in cm. between source and drain electrodes.

The chosen doping level will, of course, vary depending on the w level. The following design criteria are set forth to illustrate the respective variations in n_o and w within the critical limits.

$$n_o w > 10^{12}/\text{cm.}^2$$

$$w \approx 10^7/f$$

where f=frequency in cycles/sec.

$$\therefore n_o > 10^5 \times f$$

The band structure depicted in FIG. 2 GaAs is for the (100)-direction, that is, the energy ϵ of electrons as a function of their wave vector, $\vec{K}$, for $\vec{K}$-vectors that lie in that crystallographic direction. The $\vec{K}$-vector is the propagation vector of the De Broglie-Wave for that electron. The following relationships exist between the energy, $\epsilon(\vec{K})$ of an electron, its velocity $\vec{V}$, its effective mass tensor $\|1/m\|$ and an applied field, $\vec{F}$ ($\hbar$ is Planck's constant, divided by 2π; i and j run over x, y and z):

$$V_i = \frac{1}{\hbar}\frac{\partial\epsilon}{\partial K_i}$$

$$\left\|\frac{1}{m}\right\|_{ij} = \frac{1}{\hbar^2}\frac{\partial^2\epsilon}{\partial K_i \partial K_j}$$

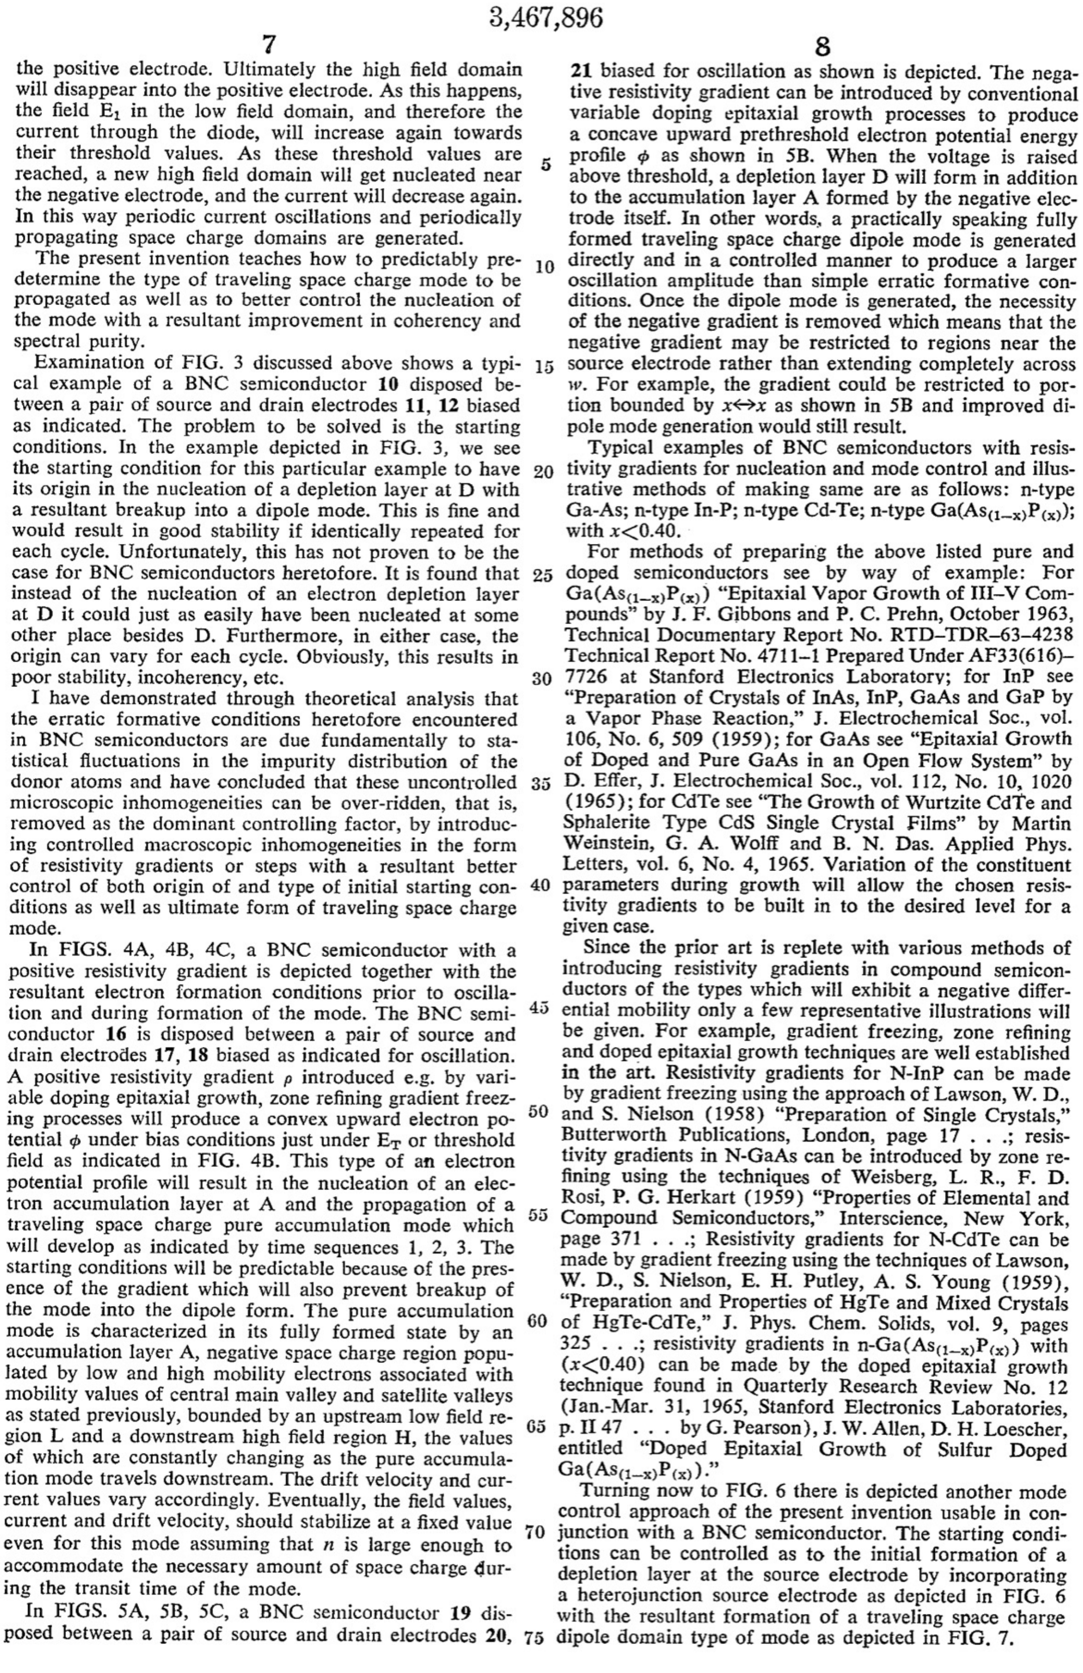
$$\frac{\partial\vec{K}}{\partial t} = -\frac{1}{\hbar}q\vec{F}$$

$$\frac{\partial\vec{V}}{\partial t} = -\left\|\frac{1}{m}\right\|\overrightarrow{qF}$$

This band structure (n-type GaAs) is characterized by a "central valley" of very low effective mass, of about 0.07 m_o accompanied by a set of "satellite valleys" along the (100)-directions, about 0.36 ev. above the central valley, and with a substantially higher effective mass the exact value of which is somewhat uncertain but which need not concern us here.

At room temperature and for low electric fields almost all the electrons are near the bottom of the central valley. Because of their low effective mass, they have the well-known high electron mobility of GaAs of over 5000 cm.^{2}/volt-sec. But this high mobility also makes it rather easy for a sufficiently strong electric field to accelerate the electrons, that is, to heat them up, to rather high energies of the order of the satellite valley energy. As this happens, the electrons can scatter into the satellite valleys where they have a much higher effective mass and thus a much lower mobility, and where they can contribute much less to the current. If this inter-valley transfer would take place only very gradually with increasing field it would merely lead to a slow decrease of the conductivity, but the overall current would keep rising with increasing field, albeit non-linearly. But as it happens, the transfer sets in rather abruptly with increasing field, and the current decrease due to electron transfer into the low-mobility satellite valleys is stronger than the current increase due to the velocity increase of those electrons that remain in the high-mobility central valley. As a result, the overall current drops and the crystal exhibits a bulk negative differential conductivity. When most of the electrons have been transferred into the satellite valleys, the current will rise again, as shown at the top of FIG. 3. But the crystal will now have a much higher resistivity, due to the much lower electron mobility in the satellite valleys. This negative differential conductivity leads to current oscillations as shown in FIG. 3. Assume that a semiconductor exhibiting a negative differential conductivity is biased with a field that lies inside the negative mobility range, say at N, and assume that this internal field is initially homogeneous. This situation is unstable. Any spatial charge or field fluctuation whatsoever, such as at D in FIG. 3, will not decay as in a medium of positive conductivity but will build up further. In the case shown in FIG. 3 this happens as follows. The field upstream of D is higher than the field downstream. Because of the negative mobility this leads to a lower electron drift velocity (and a lower current) upstream than downstream. As a result there is a net removal of electrons from around D, increasing the already existing positive space charge and the field discontinuity there. Ultimately the entire crystal will break up—electrically—into alternating "domains" of fields E_1 below and E_2 above the negative mobility range, corresponding to the same current density. The initial fluctuation at D builds up into an electron depletion layer, the accumulation layer or region of negative space charge is nucleated similarly by the opposite field discontinuity at the negative electrode itself. Since these domains consist of mobile electrons they will move along with the electrons from the negative to

Figure B.162: Herbert Kroemer invented III-V semiconductor heterostructures in 1966.



3,467,896

7

the positive electrode. Ultimately the high field domain will disappear into the positive electrode. As this happens, the field E_1 in the low field domain, and therefore the current through the diode, will increase again towards their threshold values. As these threshold values are reached, a new high field domain will get nucleated near the negative electrode, and the current will decrease again. In this way periodic current oscillations and periodically propagating space charge domains are generated.

The present invention teaches how to predictably predetermine the type of traveling space charge mode to be propagated as well as to better control the nucleation of the mode with a resultant improvement in coherency and spectral purity.

Examination of FIG. 3 discussed above shows a typical example of a BNC semiconductor **10** disposed between a pair of source and drain electrodes **11**, **12** biased as indicated. The problem to be solved is the starting conditions. In the example depicted in FIG. 3, we see the starting condition for this particular example to have its origin in the nucleation of a depletion layer at D with a resultant breakup into a dipole mode. This is fine and would result in good stability if identically repeated for each cycle. Unfortunately, this has not proven to be the case for BNC semiconductors heretofore. It is found that instead of the nucleation of an electron depletion layer at D it could just as easily have been nucleated at some other place besides D. Furthermore, in either case, the origin can vary for each cycle. Obviously, this results in poor stability, incoherency, etc.

I have demonstrated through theoretical analysis that the erratic formative conditions heretofore encountered in BNC semiconductors are due fundamentally to statistical fluctuations in the impurity distribution of the donor atoms and have concluded that these uncontrolled microscopic inhomogeneities can be over-ridden, that is, removed as the dominant controlling factor, by introducing controlled macroscopic inhomogeneities in the form of resistivity gradients or steps with a resultant better control of both origin of and type of initial starting conditions as well as ultimate form of traveling space charge mode.

In FIGS. 4A, 4B, 4C, a BNC semiconductor with a positive resistivity gradient is depicted together with the resultant electron formation conditions prior to oscillation and during formation of the mode. The BNC semiconductor **16** is disposed between a pair of source and drain electrodes **17**, **18** biased as indicated for oscillation. A positive resistivity gradient ρ introduced e.g. by variable doping epitaxial growth, zone refining gradient freezing processes will produce a convex upward electron potential ϕ under bias conditions just under E_T or threshold field as indicated in FIG. 4B. This type of an electron potential profile will result in the nucleation of an electron accumulation layer at A and the propagation of a traveling space charge pure accumulation mode which will develop as indicated by time sequences 1, 2, 3. The starting conditions will be predictable because of the presence of the gradient which will also prevent breakup of the mode into the dipole form. The pure accumulation mode is characterized in its fully formed state by an accumulation layer A, negative space charge region populated by low and high mobility electrons associated with mobility values of central main valley and satellite valleys as stated previously, bounded by an upstream low field region L and a downstream high field region H, the values of which are constantly changing as the pure accumulation mode travels downstream. The drift velocity and current values vary accordingly. Eventually, the field values, current and drift velocity, should stabilize at a fixed value even for this mode assuming that n is large enough to accommodate the necessary amount of space charge during the transit time of the mode.

In FIGS. 5A, 5B, 5C, a BNC semiconductor **19** disposed between a pair of source and drain electrodes **20**,

8

21 biased for oscillation as shown is depicted. The negative resistivity gradient can be introduced by conventional variable doping epitaxial growth processes to produce a concave upward prethreshold electron potential energy profile ϕ as shown in 5B. When the voltage is raised above threshold, a depletion layer D will form in addition to the accumulation layer A formed by the negative electrode itself. In other words, a practically speaking fully formed traveling space charge dipole mode is generated directly and in a controlled manner to produce a larger oscillation amplitude than simple erratic formative conditions. Once the dipole mode is generated, the necessity of the negative gradient is removed which means that the negative gradient may be restricted to regions near the source electrode rather than extending completely across w. For example, the gradient could be restricted to portion bounded by $x \leftrightarrow x$ as shown in 5B and improved dipole mode generation would still result.

Typical examples of BNC semiconductors with resistivity gradients for nucleation and mode control and illustrative methods of making same are as follows: n-type Ga-As; n-type In-P; n-type Cd-Te; n-type $Ga(As_{(1-x)}P_{(x)})$; with $x<0.40$.

For methods of preparing the above listed pure and doped semiconductors see by way of example: For $Ga(As_{(1-x)}P_{(x)})$ "Epitaxial Vapor Growth of III–V Compounds" by J. F. Gibbons and P. C. Prehn, October 1963, Technical Documentary Report No. RTD–TDR–63–4238 Technical Report No. 4711–1 Prepared Under AF33(616)–7726 at Stanford Electronics Laboratory; for InP see "Preparation of Crystals of InAs, InP, GaAs and GaP by a Vapor Phase Reaction," J. Electrochemical Soc., vol. 106, No. 6, 509 (1959); for GaAs see "Epitaxial Growth of Doped and Pure GaAs in an Open Flow System" by D. Effer, J. Electrochemical Soc., vol. 112, No. 10, 1020 (1965); for CdTe see "The Growth of Wurtzite CdTe and Sphalerite Type CdS Single Crystal Films" by Martin Weinstein, G. A. Wolff and B. N. Das. Applied Phys. Letters, vol. 6, No. 4, 1965. Variation of the constituent parameters during growth will allow the chosen resistivity gradients to be built in to the desired level for a given case.

Since the prior art is replete with various methods of introducing resistivity gradients in compound semiconductors of the types which will exhibit a negative differential mobility only a few representative illustrations will be given. For example, gradient freezing, zone refining and doped epitaxial growth techniques are well established in the art. Resistivity gradients for N-InP can be made by gradient freezing using the approach of Lawson, W. D., and S. Nielson (1958) "Preparation of Single Crystals," Butterworth Publications, London, page 17 . . .; resistivity gradients in N-GaAs can be introduced by zone refining using the techniques of Weisberg, L. R., F. D. Rosi, P. G. Herkart (1959) "Properties of Elemental and Compound Semiconductors," Interscience, New York, page 371 . . .; Resistivity gradients for N-CdTe can be made by gradient freezing using the techniques of Lawson, W. D., S. Nielson, E. H. Putley, A. S. Young (1959), "Preparation and Properties of HgTe and Mixed Crystals of HgTe-CdTe," J. Phys. Chem. Solids, vol. 9, pages 325 . . .; resistivity gradients in n-$Ga(As_{(1-x)}P_{(x)})$ with ($x<0.40$) can be made by the doped epitaxial growth technique found in Quarterly Research Review No. 12 (Jan.-Mar. 31, 1965, Stanford Electronics Laboratories, p. II 47 . . . by G. Pearson), J. W. Allen, D. H. Loescher, entitled "Doped Epitaxial Growth of Sulfur Doped $Ga(As_{(1-x)}P_{(x)})$."

Turning now to FIG. 6 there is depicted another mode control approach of the present invention usable in conjunction with a BNC semiconductor. The starting conditions can be controlled as to the initial formation of a depletion layer at the source electrode by incorporating a heterojunction source electrode as depicted in FIG. 6 with the resultant formation of a traveling space charge dipole domain type of mode as depicted in FIG. 7.

Figure B.163: Herbert Kroemer invented III-V semiconductor heterostructures in 1966.

The BNC semiconductor main body **30** depicted in FIG. 6 has a width w disposed between a pair of source and drain electrodes with a pair of leads **33, 34** if desired.

The source electrode in the case of n-type BNC diodes is the origin of the traveling space charge instability and the drain electrode is the exit for the traveling space charge instability. According to the further teachings of this invention by making the source electrode **31** include a heterojunction electrode **35** with the following characteristics,

(a) Higher resistivity than the oscillating body portion w
(b) Not exhibiting a negative conductivity at the electric fields reached during oscillation of the oscillating semiconductor,

improved frequency stability will result. The remaining portion, if any, of the source electrode can be a simple alloyed metal contact **36** such as tin or any other high conductivity contact electrode such as a heavily doped (degenerate) n^+ semiconductor of the same material to facilitate integration into integrated circuits. The drain electrode **32** is also preferably a high conductivity type of electrode such as for example, an ohmic metal electrode of tin. Alternatively, as mentioned above for facilitation of incorporation of the BNC semiconductors of the present invention in integrated circuit environments the metal electrode portions **36, 32** can be replaced with epitaxially grown layers of the same semiconductor as they are grown on only more heavily doped such that $n_c w > nw$ where n_c in this case is the electron conduction or carrier number density of the n-type semiconductor electrode portions **36, 32**. In other words, the important aspect of this type of mode control is the utilization of a heterojunction source electrode **35**. If desired, the heterojunction source electrode **35** can include a metal, or n^+ (degenerate) portion or metal pressure contact or other type of high conductivity electrode.

With the above indicated type of hetrojunction source electrode incorporated in a BNC semiconductor oscillator controlled dipole domain formation will result as indicated in FIG. 7. Initially, a depletion layer D will be nucleated directly at the heterojunction interface **38** bounded on the upstream side by a high field region F_{H1} and on the downstream side by a low field region F_{L1}. This space charge instability will commence propagation toward the drain electrode and will, practically speaking, immediately begin breakup of the high field region to cause nucleation of an accumulation layer A_2 upstream from the depletion layer at the next illustrative time interval represented by depletion layer D_2. From this point on the dipole domain continues development into its fully mature form such as indicated at time interval **3**, and ultimately propagates out the drain electrode at which point the cycle will repeat itself ad infinitum under stable bias and load conditions with $f \approx v_L/w$.

A suitable material for the hetrojunction control electrode **35** will obey the aforementioned criteria of:

$$\rho_h > \rho_B$$

where:

ρ_h=resistivity of the heterojunction control electrode,
ρ_B=resistivity of the BNC semiconductor body and σ_h is positive over the operating range of the device where σ_h=conductivity of the heterojunction control electrode.

Suitable relative ratios between ρ_h and ρ_B are that ρ_h exceed ρ_B by 10% or more as computed at the operating temperature and zero bias.

The techniques for measuring conductivity and resistivity are well known in the art. For example, see an article by L. J. Van der Pauw, "A Method of Measuring Specific Resistivity and Hall Effect of Discs of Arbitrary Shape," Philips Research Reports, vol. 13, p. 1 (1958).

A few specific examples of suitable heterojunction control electrode semiconductors utilizable in conjunction with a BNC body made of n-type GaAs are as follows:

n-GaP
n-GaAs-GaP mixture with more than 50% GaP

$$\mathrm{Ga}(\mathrm{As}_{(1-x)}-\mathrm{P}_{(x)})$$

with $x > .5$
n-Ge

and any other semiconductors not exhibiting a negative conductivity.

The thickness dimension t of the heterojunction control electrode will be less than w (preferably as thin as feasible) to facilitate formation of the high field region in a short time span for efficiency considerations. A typical illustrative example is 1 micron.

As mentioned previously, other types of BNC semiconductors are known beside n-type GaAs such as listed in the introduction. In each case the heterojunction control electrode material is easily selected from any known semiconductors with the restriction that $\rho_h > \rho_B$ and σ_h be positive.

Good practice would be to select III–V semiconductors as heterojunction control electrodes when the BNC main body is a III–V compound and II–VI semiconductors as heterojunction control electrodes when the BNC main body is a II–VI semiconductor. Ge can be used with both III–V main body semiconductors and II–VI main body semiconductors. The heterojunction control electrodes are preferably epitaxially deposited in manners well known in the art.

The following articles are cited to provide representative techniques for building heterojunction control electrodes having the above set forth properties.

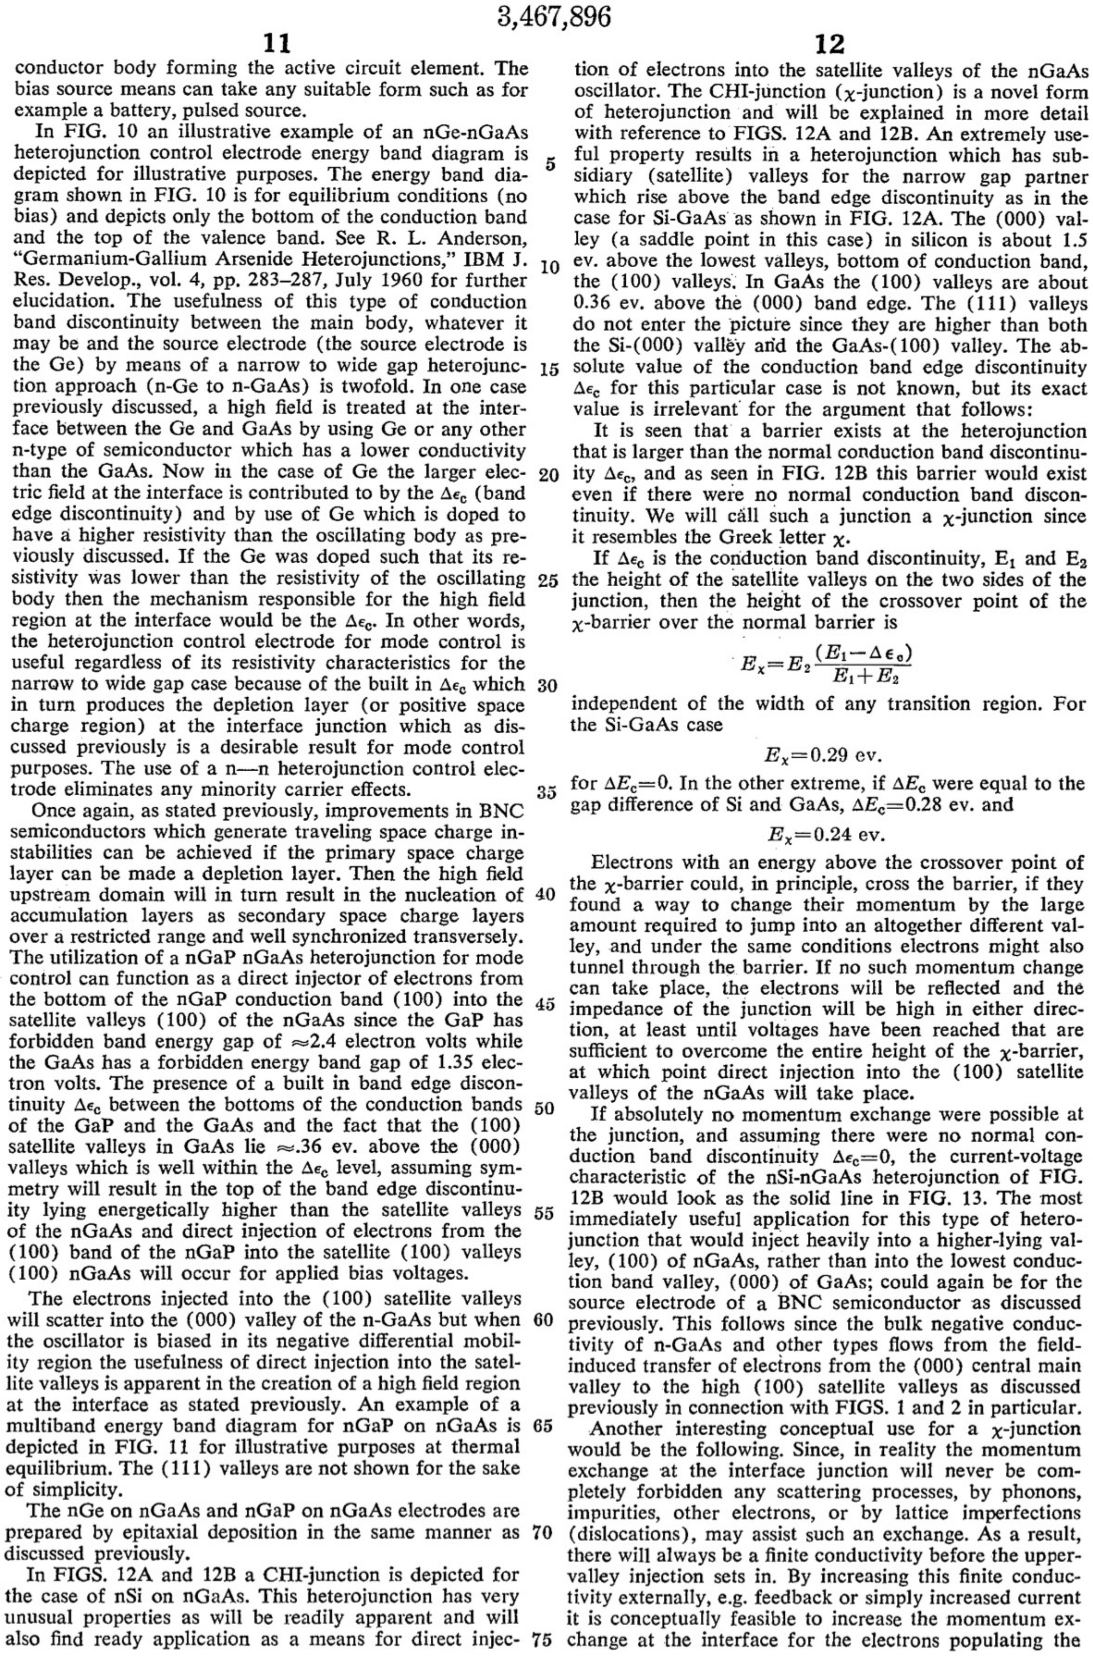
The deposition of n-Ge on -nGaAs is taught in an article by J. C. Marinace "Tunnel Diodes by Vapor Growth of Ge on Ge and on GaAs," IBM Journal of Res. and Dev., Vol. 4, No. 3, July 1960. The deposition of n-Ge on n-InP is set forth in an article entitled "Growth of Germanium Epitaxial Layers by the Pyrolysis of Germane" RCA Review, December 1963, No. 4, p. 499. This deposition technique can also be used for the deposition of n-Ge on n-CdTe and n-$\mathrm{Ga}(\mathrm{As}_{(1-x)}\mathrm{P}_{(x)})$ with $x < 0.40$. The deposition of n-GaP on n-GaAs and n-$\mathrm{Ga}(\mathrm{As}_{(1-x)}\mathrm{P}_{(x)})$ with $x > .5$ on n-GaAs is taught in NASA Research Grant No. NSG-555 Tech. Report No. 5108–1 by Yen-sun Chen, October 1965.

As discussed previously, the heterojunction control electrode will of necessity be the source electrode for mode control. The source electrode can also include a high conductivity portion such as alloyed tin portion **36** metal pressure contact or n^+ similar semiconductor as illustrated in FIGS. 8A, 8B, and 8C. The drain electrode will preferably be similar. In FIG. 8A the BNC diode with heterojunction control electrode is the same as in FIG. 6.

In FIG. 8B the tin electrode portions are replaced with metal pressure contacts **39** and in FIG. 8C the n^+ electrode scheme is used.

In FIG. 9 a typical schematic circuit of a microwave generator employing the bulk negative conductivity semiconductor with built in mode control means as the active element is depicted. The circuit includes a low pass filter section **50**, active element **51**, bias source means **52** and output terminals **53** for extracting the microwave energy. The circuit includes series and shunt capacitors **54, 55** for varying the coupling to the load and blocking the bias voltage from the load and for tuning the operating frequency of the generator. The particular oscillator depicted in FIG. 9 is merely an illustrative example of one of many possible forms which can be implemented by suitable microwave circuitry. For example, see an article by P. N. Robson and S. M. Mahrous in The Radio and Electronic Engineer, December 1965, pages 345–352, for a typical coaxial version of a microwave oscillator using the internal oscillations generated in a bulk negative conductivity semi-

Figure B.164: Herbert Kroemer invented III-V semiconductor heterostructures in 1966.



conductor body forming the active circuit element. The bias source means can take any suitable form such as for example a battery, pulsed source.

In FIG. 10 an illustrative example of an nGe-nGaAs heterojunction control electrode energy band diagram is depicted for illustrative purposes. The energy band diagram shown in FIG. 10 is for equilibrium conditions (no bias) and depicts only the bottom of the conduction band and the top of the valence band. See R. L. Anderson, "Germanium-Gallium Arsenide Heterojunctions," IBM J. Res. Develop., vol. 4, pp. 283–287, July 1960 for further elucidation. The usefulness of this type of conduction band discontinuity between the main body, whatever it may be and the source electrode (the source electrode is the Ge) by means of a narrow to wide gap heterojunction approach (n-Ge to n-GaAs) is twofold. In one case previously discussed, a high field is treated at the interface between the Ge and GaAs by using Ge or any other n-type of semiconductor which has a lower conductivity than the GaAs. Now in the case of Ge the larger electric field at the interface is contributed to by the $\Delta\epsilon_c$ (band edge discontinuity) and by use of Ge which is doped to have a higher resistivity than the oscillating body as previously discussed. If the Ge was doped such that its resistivity was lower than the resistivity of the oscillating body then the mechanism responsible for the high field region at the interface would be the $\Delta\epsilon_c$. In other words, the heterojunction control electrode for mode control is useful regardless of its resistivity characteristics for the narrow to wide gap case because of the built in $\Delta\epsilon_c$ which in turn produces the depletion layer (or positive space charge region) at the interface junction which as discussed previously is a desirable result for mode control purposes. The use of a n—n heterojunction control electrode eliminates any minority carrier effects.

Once again, as stated previously, improvements in BNC semiconductors which generate traveling space charge instabilities can be achieved if the primary space charge layer can be made a depletion layer. Then the high field upstream domain will in turn result in the nucleation of accumulation layers as secondary space charge layers over a restricted range and well synchronized transversely. The utilization of a nGaP nGaAs heterojunction for mode control can function as a direct injector of electrons from the bottom of the nGaP conduction band (100) into the satellite valleys (100) of the nGaAs since the GaP has forbidden band energy gap of ≈2.4 electron volts while the GaAs has a forbidden energy band gap of 1.35 electron volts. The presence of a built in band edge discontinuity $\Delta\epsilon_c$ between the bottoms of the conduction bands of the GaP and the GaAs and the fact that the (100) satellite valleys in GaAs lie ≈.36 ev. above the (000) valleys which is well within the $\Delta\epsilon_c$ level, assuming symmetry will result in the top of the band edge discontinuity lying energetically higher than the satellite valleys of the nGaAs and direct injection of electrons from the (100) band of the nGaP into the satellite (100) valleys (100) nGaAs will occur for applied bias voltages.

The electrons injected into the (100) satellite valleys will scatter into the (000) valley of the n-GaAs but when the oscillator is biased in its negative differential mobility region the usefulness of direct injection into the satellite valleys is apparent in the creation of a high field region at the interface as stated previously. An example of a multiband energy band diagram for nGaP on nGaAs is depicted in FIG. 11 for illustrative purposes at thermal equilibrium. The (111) valleys are not shown for the sake of simplicity.

The nGe on nGaAs and nGaP on nGaAs electrodes are prepared by epitaxial deposition in the same manner as discussed previously.

In FIGS. 12A and 12B a CHI-junction is depicted for the case of nSi on nGaAs. This heterojunction has very unusual properties as will be readily apparent and will also find ready application as a means for direct injection of electrons into the satellite valleys of the nGaAs oscillator. The CHI-junction (χ-junction) is a novel form of heterojunction and will be explained in more detail with reference to FIGS. 12A and 12B. An extremely useful property results in a heterojunction which has subsidiary (satellite) valleys for the narrow gap partner which rise above the band edge discontinuity as in the case for Si-GaAs as shown in FIG. 12A. The (000) valley (a saddle point in this case) in silicon is about 1.5 ev. above the lowest valleys, bottom of conduction band, the (100) valleys. In GaAs the (100) valleys are about 0.36 ev. above the (000) band edge. The (111) valleys do not enter the picture since they are higher than both the Si-(000) valley and the GaAs-(100) valley. The absolute value of the conduction band edge discontinuity $\Delta\epsilon_c$ for this particular case is not known, but its exact value is irrelevant for the argument that follows:

It is seen that a barrier exists at the heterojunction that is larger than the normal conduction band discontinuity $\Delta\epsilon_c$, and as seen in FIG. 12B this barrier would exist even if there were no normal conduction band discontinuity. We will call such a junction a χ-junction since it resembles the Greek letter χ.

If $\Delta\epsilon_c$ is the conduction band discontinuity, E_1 and E_2 the height of the satellite valleys on the two sides of the junction, then the height of the crossover point of the χ-barrier over the normal barrier is

$$E_x = E_2 \frac{(E_1 - \Delta\epsilon_c)}{E_1 + E_2}$$

independent of the width of any transition region. For the Si-GaAs case

$$E_x = 0.29 \text{ ev.}$$

for $\Delta E_c = 0$. In the other extreme, if ΔE_c were equal to the gap difference of Si and GaAs, $\Delta E_c = 0.28$ ev. and

$$E_x = 0.24 \text{ ev.}$$

Electrons with an energy above the crossover point of the χ-barrier could, in principle, cross the barrier, if they found a way to change their momentum by the large amount required to jump into an altogether different valley, and under the same conditions electrons might also tunnel through the barrier. If no such momentum change can take place, the electrons will be reflected and the impedance of the junction will be high in either direction, at least until voltages have been reached that are sufficient to overcome the entire height of the χ-barrier, at which point direct injection into the (100) satellite valleys of the nGaAs will take place.

If absolutely no momentum exchange were possible at the junction, and assuming there were no normal conduction band discontinuity $\Delta\epsilon_c = 0$, the current-voltage characteristic of the nSi-nGaAs heterojunction of FIG. 12B would look as the solid line in FIG. 13. The most immediately useful application for this type of heterojunction that would inject heavily into a higher-lying valley, (100) of nGaAs, rather than into the lowest conduction band valley, (000) of GaAs; could again be for the source electrode of a BNC semiconductor as discussed previously. This follows since the bulk negative conductivity of n-GaAs and other types flows from the field-induced transfer of electrons from the (000) central main valley to the high (100) satellite valleys as discussed previously in connection with FIGS. 1 and 2 in particular.

Another interesting conceptual use for a χ-junction would be the following. Since, in reality the momentum exchange at the interface junction will never be completely forbidden any scattering processes, by phonons, impurities, other electrons, or by lattice imperfections (dislocations), may assist such an exchange. As a result, there will always be a finite conductivity before the upper-valley injection sets in. By increasing this finite conductivity externally, e.g. feedback or simply increased current it is conceptually feasible to increase the momentum exchange at the interface for the electrons populating the

13

(100) conduction band bottom of the nSi (low mobility high effective mass) such that they transfer into the (000) main valley of the nGaAs (high mobility-low effective mass) prior to the onset of injection into the higher satellite valleys of the wide gap partner. The result of this process would produce a negative resistance as shown in the dashed line of FIG. 13. Both electron-electron scattering and multiple phonon processes could lead to such a negative resistance at high current values and low voltages. Standard Si technology may be used to prepare the χ-junction in conjunction with the more recently developed epitaxial GaAs techniques. See, by way of example, R. S. Wagner and W. C. Ellis, "Vapor-Liquid-Solid Mechanism of Single Crystal Growth," Appl. Phys. Lett., vol. 4, pp. 89–90, March 1964 and the previously cited article by D. Effer entitled "Epitaxial Growth of Doped and Pure GaAs in an Open Flow System," J. Electrochemical Soc., vol. 112, No. 10, 1020 (1965).

In brief summary then, the present invention teaches several novel ways of obtaining improved control over the traveling space charge instabilities associated with the BNC semiconductor. The techniques include appropriate narrow to wide gap resistivity types; wide to narrow gap for direct injection; χ-junction; and resistivity gradients in bulk material itself.

Since many changes could be made in the above construction and many apparently widely different embodiments of this invention could be made without departing from the scope thereof, it is intended that all matter contained in the above description or shown in the accompanying drawings shall be interpreted as illustrative and not in a limiting sense.

What is claimed is:

1. A semiconductor microwave oscillator device comprising: an active element including a main body of semiconductor material characterized by having a drift velocity vs. electric field dependence with a region of negative differential mobility, said semiconductor main body being disposed between source and drain electrodes, and further characterized by generating internal traveling space charge domains upon being biased in its region of negative differential mobility, said semiconductor device being provided with means for predetermining the type of traveling space charge mode, said means comprising a heterojunction source control electrode, characterized by being made from a semiconductor material having a resistivity

$$\rho_h > \rho_B$$

where ρ_h is the resistivity of said heterojunction control electrode material, and ρ_B is the resistivity of said main body semiconductor, said heterojunction control electrode being further characterized by having a positive mobility over the operating range of the device.

2. The semiconductor microwave oscillator defined in claim **1** wherein said heterojunction source electrode is GaP and said semiconductor main body is n-type GaAs.

3. The semiconductor microwave oscillator defined in claim **1** wherein said heterojunction source electrode is Si and said semiconductor main body is n-type GaAs.

14

4. A semiconductor microwave oscillator device comprising a main body of semiconductor material characterized by having a drift velocity vs. electric field dependence with a region of negative differential mobility, said semiconductor main body being disposed between source and drain electrodes, and further characterized by generating internal traveling space charge domains upon being biased in its region of negative differential mobility, said semiconductor device being provided with means for predetermining the type of traveling space charge mode which will propagate between said source and drain electrodes, said means for predetermining comprising a resistivity gradient in said main body in the direction of electron flow between said source and drain electrodes, said resistivity gradient falling within the range of 1% to 20% of the average resistivity of the main semiconductor body.

5. The device defined in claim **4** wherein said resistivity gradient is positive in the direction of propagation of said traveling space charge mode thereby causing formation of an accumulation mode.

6. The device defined in claim **4** wherein said resistivity gradient is negative in the direction of propagation of said traveling space charge mode thereby causing formation of a dipole mode.

7. A semiconductor microwave oscillator device comprising an active element including a main body of semiconductor material characterized by having a drift velocity vs. electric field dependence with a region of negative differential mobility, said semiconductor main body being disposed between source and drain electrodes, and further characterized by generating internal traveling space charge domains upon being biased in its region of negative differential mobility, said semiconductor device being provided with means for predetermining the type of traveling space charge mode which will propagate, said means for predetermining being a heterojunction source control electrode, said heterojunction source control electrode being an n-type semiconductor having a larger forbidden band gap than the forbidden gap of said body n-type semiconductor material.

METHOD OF MANUFACTURING SEMICONDUCTOR DEVICES

Jean A. Hoerni, Los Altos, Calif., assignor, by mesne assignments, to Fairchild Camera and Instrument Corporation, Syosset, N.Y., a corporation of Delaware

Filed May 1, 1959, Ser. No. 810,388
11 Claims. (Cl. 29—25.3)

The present invention relates to an improvement in the manufacture of semiconductor devices including transistors and to an improved transistor structure. More particularly, the invention relates, as to the method thereof, to the control of semiconductor diffusing and masking to the end of producing an improved diffusion transistor having fully protected junctions and maximized exposed surfaces for ohmic contact attachment.

Advancements in transistor technology have in part been directed to the production of very small sized transistor structures, inasmuch as minute semiconductor geometries are required for high frequency applications of transistors. While the well known point-contact transistor is adapted for high frequency work, yet certain limitations attach to this type of transistor and consequently junction transistors have been developed for use in the high frequency range. One type of junction transistor which is particularly well adapted for high frequency applications is the double-diffused silicon transistor, and although the present invention is adapted for use with other types of transistors it is with respect to double-diffused silicon transistors that the following description is referenced.

As regards the manufacture of double-diffused silicon transistors, and in fact any minute transistor structure, difficulty is encountered in providing a sufficient exposed area of the base material for attachment of an ohmic contact thereto. By maintaining the extremely small element dimensions required of the transistor, there results only a minute thickness of base material exposed between the base-collector junction and the emitter-base junction on a transistor surface. Conventional transistor utility requires the provision of electrical contacts to the individual transistor elements or portions, and thus it is necessary for the dimensions of the base portion to be made sufficient to attach such contacts. In certain instances this limitation upon the size of the base portion is highly undesirable, inasmuch as conventional manufacturing practices produce a base thickness in proportion to the exposed base width.

Another difficulty arising from the limited size necessary for transistors to suitably operate at very high frequencies is encountered in the difficulty of protecting the transistor junction. This is particularly noted in the attachment of electrical contacts to the transistor portions inasmuch as very minute variations in the placement of electrical conductors or ohmic contacts to the transistor may well result in electrically shorting of the transistor junction, whereby the transistor structure is unsuited for use and must be rejected. This latter problem is compounded by the necessity in high-frequency transistors of employing an ohmic contact which substantially entirely covers the exposed surface of each of the elements in order to minimize the spreading resistance thereof. Conventional plating methods are unsuited for the provision of such ohmic contacts to within fractions of a millimeter from the transistor junction, as is normally required for transistor structures capable of operating at very high frequencies. Not only is the problem of providing suitable ohmic contacts to the transistor portions a major one, but also the possible damage or other types of inadvertent electrical shorting of the transistor junctions during manufacturing processes is of major importance in limiting the number of rejects in any manufacturing process. Additionally, long range contamination of transistor junctions may be a cause of drifting and deteriorization of transistor characteristics.

There have been developed for high frequency applications transistors of the "mesa" design wherein undesirable lateral extensions of the base-collector junction are removed by etching to produce transistors of very small dimensions. Although mesa transistors have found wide acceptance in the art, the junction exposed by the etching, as well as the other junction, is particularly vulnerable to contamination or degradation during subsequent portions of the manufacturing process. In accordance with the present invention there is produced a transistor having the minute dimensions of the mesa type, but with the unit at all times completely embedded in the semiconductor. In the process hereof, the transistor junctions are at all times fully protected by an oxide layer or coating formed simultaneously with the junction during diffusion at high temperatures so that no contamination of the transistor junctions during or after manufacture is possible. In this manner one of the major causes of transistor failure is entirely precluded.

The present invention provides a method of transistor manufacture overcoming the above-noted problems as well as others prevalent in the art. In the manufacture of transistors it is not uncommon for the semiconducting material to become oxidized on the exterior surfaces thereof, and it is conventional during manufacture to remove this outside coating as by etching, although it has been proposed ot leave a certain portion of this coating upon the transistor surface as a protection for portions thereof. The present invention provides, as integral steps in the manufacture of transistors, the control of the extent and position of semiconductor coating which serves the purpose of thereby delineating the exact lateral configuration of materials diffused into the semiconducting material and furthermore to provide a subsequent protection for the transistor surface. In accordance with the present invention it is possible not only to limit the extent of impurities diffusion in a semiconductor during the formation of different types of semiconductor, but furthermore, by the addition and subtraction of a masking layer or coating upon exposed transistor surfaces, it is herein possible to provide a precisely controlled area of any particular transistor material upon a common transistor surface. In addition, and in accordance with the present invention, there is herein provided, by the retention of a protective coating upon exposed transistor surfaces, means for preventing electrical shorting of transistor junctions and/or damage thereto during fabrication and manufacture of the transistor devices.

It is an object of the present invention to provide an improved method of manufacturing semiconductor devices wherein maximum surface protection of a device is afforded.

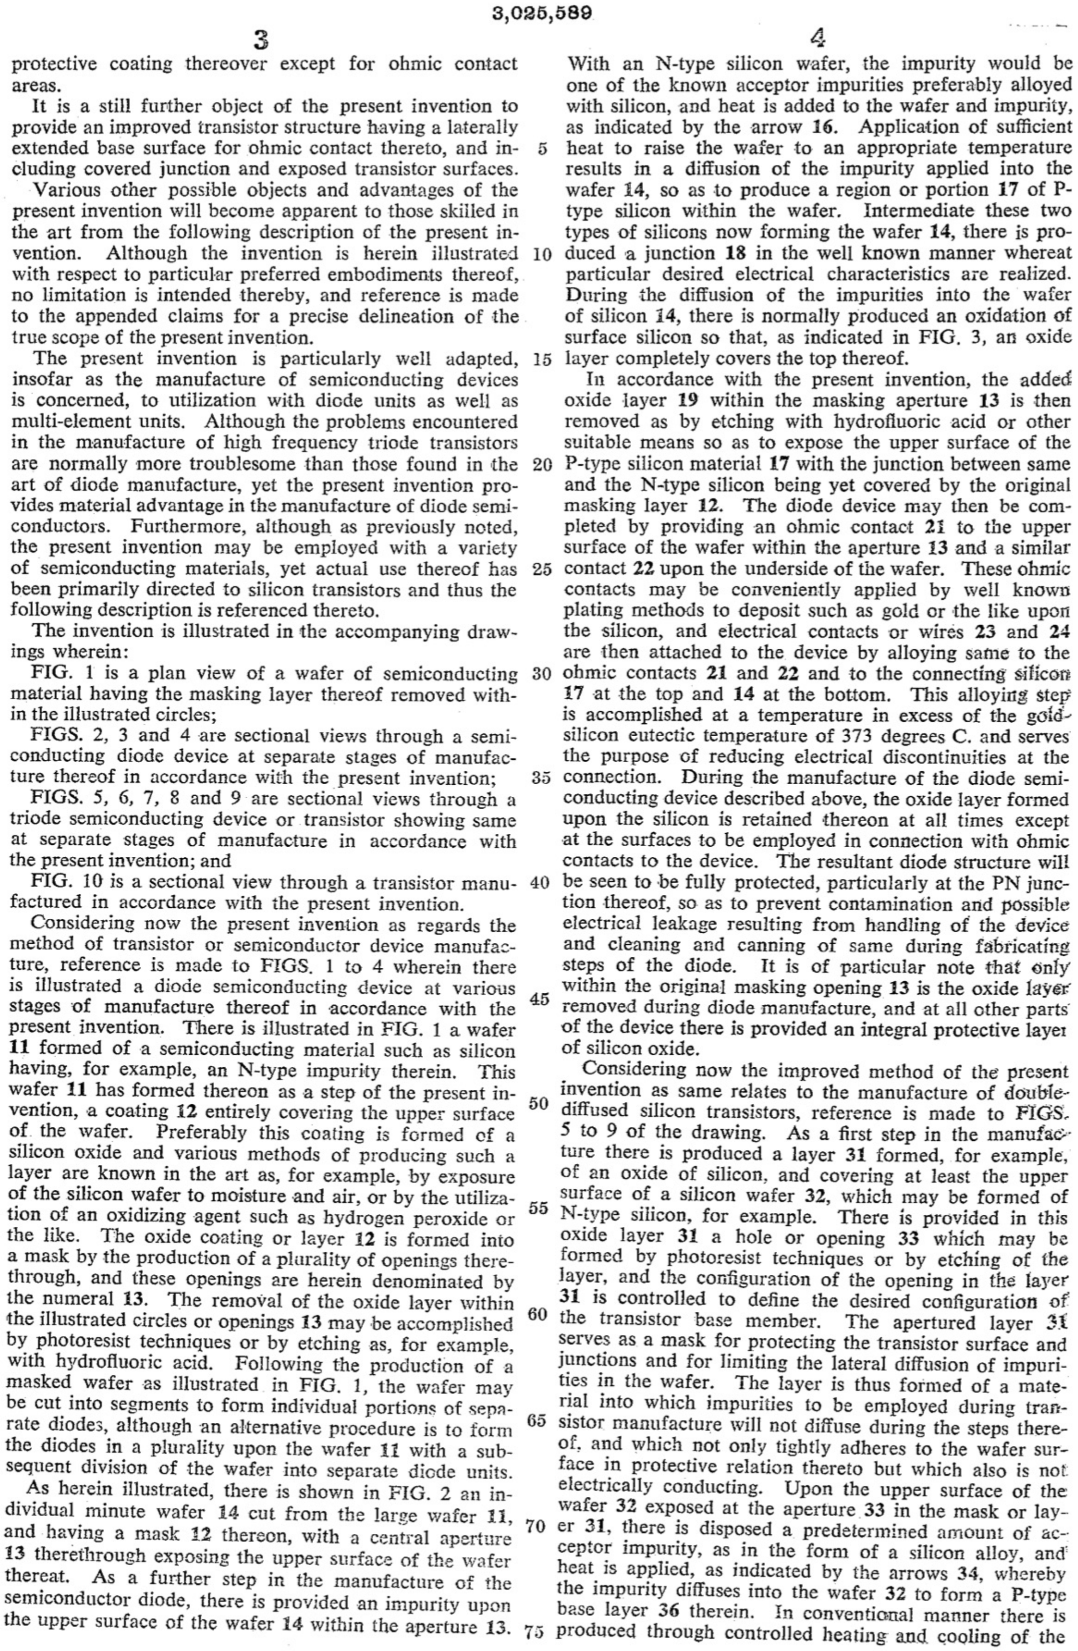
It is another object of the present invention to provide an improved method of manufacturing semiconductor devices wherein precise control is attained over lateral extent of diffused impurities therein.

It is a further object of the present invention to provide an improved method of transistor manufacture employing masking for controlling the extent of base surface area of minute double-diffused transistors.

It is yet another object of the present invention to provide a method of transistor manufacture including the addition of further masking to limit the diffusion of a second impurity in double-diffused transistors for maximizing the base surface area available for ohmic contacts, and additionally protecting transistor surfaces.

It is still another object of the present invention to provide an improved semiconducting device having a

Figure B.168: Jean Hoerni invented methods of manufacturing silicon transistors.



3,025,589

3

protective coating thereover except for ohmic contact areas.

It is a still further object of the present invention to provide an improved transistor structure having a laterally extended base surface for ohmic contact thereto, and including covered junction and exposed transistor surfaces.

Various other possible objects and advantages of the present invention will become apparent to those skilled in the art from the following description of the present invention. Although the invention is herein illustrated with respect to particular preferred embodiments thereof, no limitation is intended thereby, and reference is made to the appended claims for a precise delineation of the true scope of the present invention.

The present invention is particularly well adapted, insofar as the manufacture of semiconducting devices is concerned, to utilization with diode units as well as multi-element units. Although the problems encountered in the manufacture of high frequency triode transistors are normally more troublesome than those found in the art of diode manufacture, yet the present invention provides material advantage in the manufacture of diode semiconductors. Furthermore, although as previously noted, the present invention may be employed with a variety of semiconducting materials, yet actual use thereof has been primarily directed to silicon transistors and thus the following description is referenced thereto.

The invention is illustrated in the accompanying drawings wherein:

FIG. 1 is a plan view of a wafer of semiconducting material having the masking layer thereof removed within the illustrated circles;

FIGS. 2, 3 and 4 are sectional views through a semiconducting diode device at separate stages of manufacture thereof in accordance with the present invention;

FIGS. 5, 6, 7, 8 and 9 are sectional views through a triode semiconducting device or transistor showing same at separate stages of manufacture in accordance with the present invention; and

FIG. 10 is a sectional view through a transistor manufactured in accordance with the present invention.

Considering now the present invention as regards the method of transistor or semiconductor device manufacture, reference is made to FIGS. 1 to 4 wherein there is illustrated a diode semiconducting device at various stages of manufacture thereof in accordance with the present invention. There is illustrated in FIG. 1 a wafer **11** formed of a semiconducting material such as silicon having, for example, an N-type impurity therein. This wafer **11** has formed thereon as a step of the present invention, a coating **12** entirely covering the upper surface of the wafer. Preferably this coating is formed of a silicon oxide and various methods of producing such a layer are known in the art as, for example, by exposure of the silicon wafer to moisture and air, or by the utilization of an oxidizing agent such as hydrogen peroxide or the like. The oxide coating or layer **12** is formed into a mask by the production of a plurality of openings therethrough, and these openings are herein denominated by the numeral **13**. The removal of the oxide layer within the illustrated circles or openings **13** may be accomplished by photoresist techniques or by etching as, for example, with hydrofluoric acid. Following the production of a masked wafer as illustrated in FIG. 1, the wafer may be cut into segments to form individual portions of separate diodes, although an alternative procedure is to form the diodes in a plurality upon the wafer **11** with a subsequent division of the wafer into separate diode units.

As herein illustrated, there is shown in FIG. 2 an individual minute wafer **14** cut from the large wafer **11**, and having a mask **12** thereon, with a central aperture **13** therethrough exposing the upper surface of the wafer thereat. As a further step in the manufacture of the semiconductor diode, there is provided an impurity upon the upper surface of the wafer **14** within the aperture **13**.

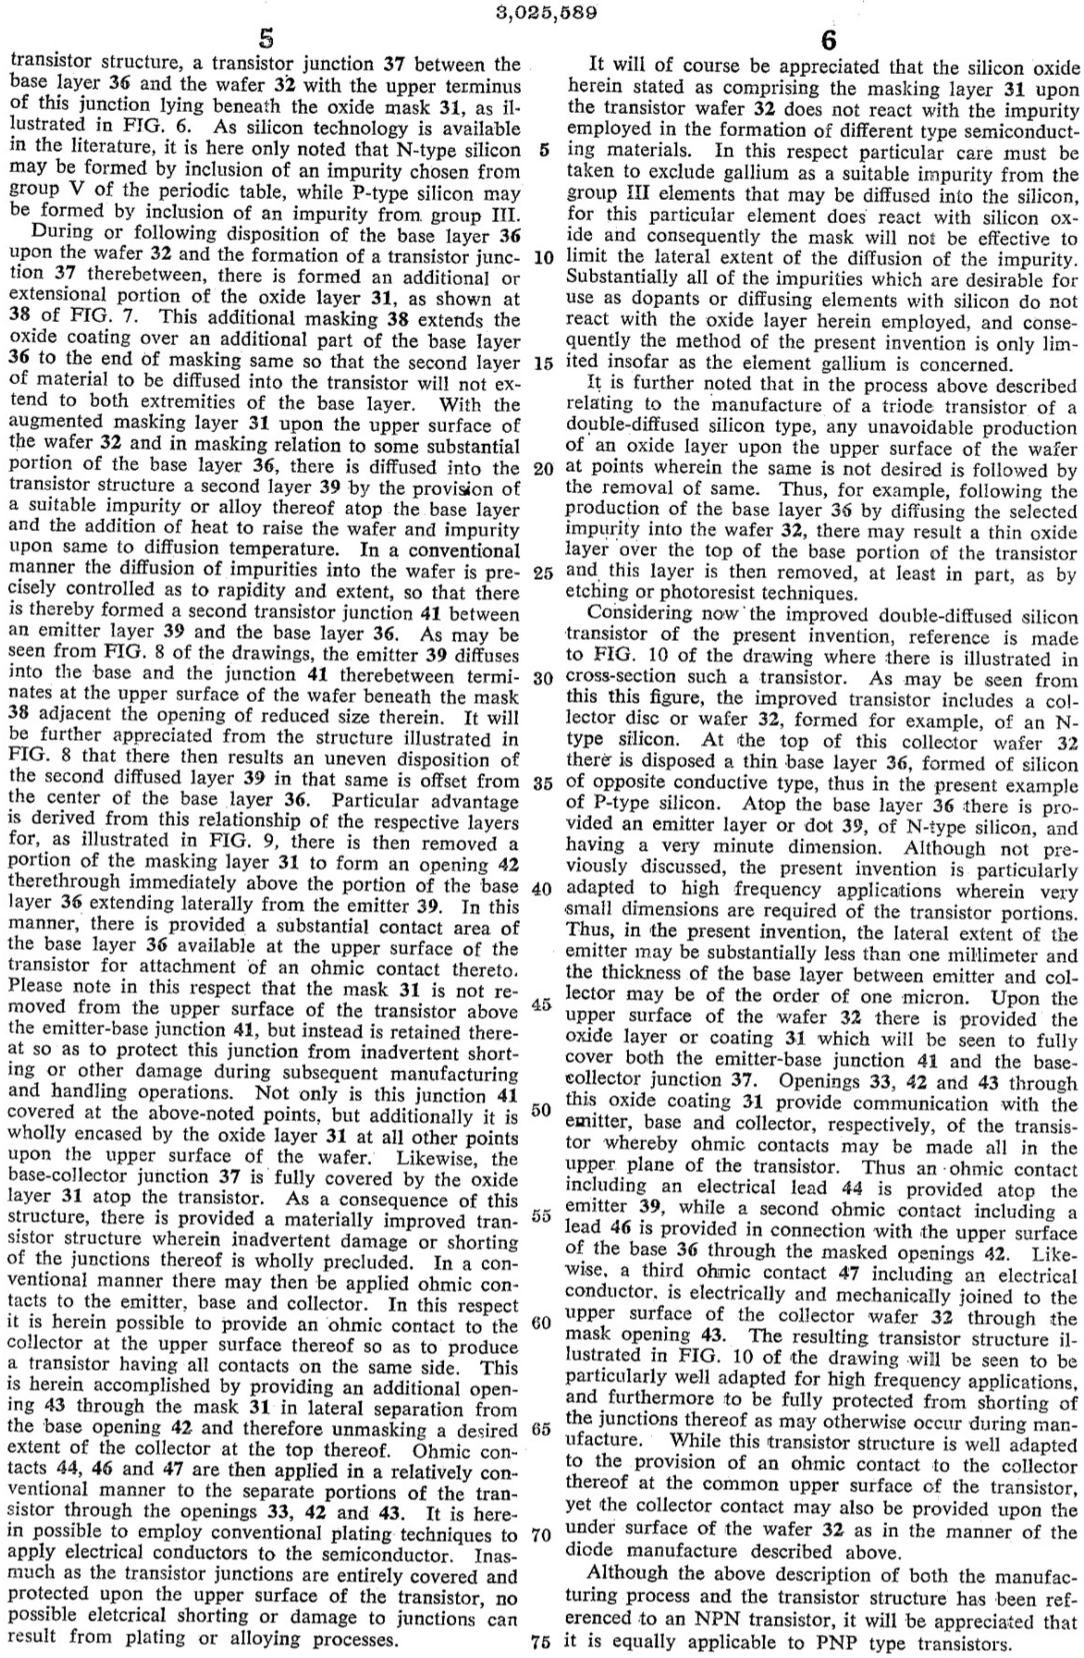
4

With an N-type silicon wafer, the impurity would be one of the known acceptor impurities preferably alloyed with silicon, and heat is added to the wafer and impurity, as indicated by the arrow **16**. Application of sufficient heat to raise the wafer to an appropriate temperature results in a diffusion of the impurity applied into the wafer **14**, so as to produce a region or portion **17** of P-type silicon within the wafer. Intermediate these two types of silicons now forming the wafer **14**, there is produced a junction **18** in the well known manner whereat particular desired electrical characteristics are realized. During the diffusion of the impurities into the wafer of silicon **14**, there is normally produced an oxidation of surface silicon so that, as indicated in FIG. 3, an oxide layer completely covers the top thereof.

In accordance with the present invention, the added oxide layer **19** within the masking aperture **13** is then removed as by etching with hydrofluoric acid or other suitable means so as to expose the upper surface of the P-type silicon material **17** with the junction between same and the N-type silicon being yet covered by the original masking layer **12**. The diode device may then be completed by providing an ohmic contact **21** to the upper surface of the wafer within the aperture **13** and a similar contact **22** upon the underside of the wafer. These ohmic contacts may be conveniently applied by well known plating methods to deposit such as gold or the like upon the silicon, and electrical contacts or wires **23** and **24** are then attached to the device by alloying same to the ohmic contacts **21** and **22** and to the connecting silicon **17** at the top and **14** at the bottom. This alloying step is accomplished at a temperature in excess of the gold-silicon eutectic temperature of 373 degrees C. and serves the purpose of reducing electrical discontinuities at the connection. During the manufacture of the diode semiconducting device described above, the oxide layer formed upon the silicon is retained thereon at all times except at the surfaces to be employed in connection with ohmic contacts to the device. The resultant diode structure will be seen to be fully protected, particularly at the PN junction thereof, so as to prevent contamination and possible electrical leakage resulting from handling of the device and cleaning and canning of same during fabricating steps of the diode. It is of particular note that only within the original masking opening **13** is the oxide layer removed during diode manufacture, and at all other parts of the device there is provided an integral protective layer of silicon oxide.

Considering now the improved method of the present invention as same relates to the manufacture of double-diffused silicon transistors, reference is made to FIGS. 5 to 9 of the drawing. As a first step in the manufacture there is produced a layer **31** formed, for example, of an oxide of silicon, and covering at least the upper surface of a silicon wafer **32**, which may be formed of N-type silicon, for example. There is provided in this oxide layer **31** a hole or opening **33** which may be formed by photoresist techniques or by etching of the layer, and the configuration of the opening in the layer **31** is controlled to define the desired configuration of the transistor base member. The apertured layer **31** serves as a mask for protecting the transistor surface and junctions and for limiting the lateral diffusion of impurities in the wafer. The layer is thus formed of a material into which impurities to be employed during transistor manufacture will not diffuse during the steps thereof, and which not only tightly adheres to the wafer surface in protective relation thereto but which also is not electrically conducting. Upon the upper surface of the wafer **32** exposed at the aperture **33** in the mask or layer **31**, there is disposed a predetermined amount of acceptor impurity, as in the form of a silicon alloy, and heat is applied, as indicated by the arrows **34**, whereby the impurity diffuses into the wafer **32** to form a P-type base layer **36** therein. In conventional manner there is produced through controlled heating and cooling of the

Figure B.169: Jean Hoerni invented methods of manufacturing silicon transistors.



3,025,589

5

transistor structure, a transistor junction **37** between the base layer **36** and the wafer **32** with the upper terminus of this junction lying beneath the oxide mask **31**, as illustrated in FIG. 6. As silicon technology is available in the literature, it is here only noted that N-type silicon may be formed by inclusion of an impurity chosen from group V of the periodic table, while P-type silicon may be formed by inclusion of an impurity from group III.

During or following disposition of the base layer **36** upon the wafer **32** and the formation of a transistor junction **37** therebetween, there is formed an additional or extensional portion of the oxide layer **31**, as shown at **38** of FIG. 7. This additional masking **38** extends the oxide coating over an additional part of the base layer **36** to the end of masking same so that the second layer of material to be diffused into the transistor will not extend to both extremities of the base layer. With the augmented masking layer **31** upon the upper surface of the wafer **32** and in masking relation to some substantial portion of the base layer **36**, there is diffused into the transistor structure a second layer **39** by the provision of a suitable impurity or alloy thereof atop the base layer and the addition of heat to raise the wafer and impurity upon same to diffusion temperature. In a conventional manner the diffusion of impurities into the wafer is precisely controlled as to rapidity and extent, so that there is thereby formed a second transistor junction **41** between an emitter layer **39** and the base layer **36**. As may be seen from FIG. 8 of the drawings, the emitter **39** diffuses into the base and the junction **41** therebetween terminates at the upper surface of the wafer beneath the mask **38** adjacent the opening of reduced size therein. It will be further appreciated from the structure illustrated in FIG. 8 that there then results an uneven disposition of the second diffused layer **39** in that same is offset from the center of the base layer **36**. Particular advantage is derived from this relationship of the respective layers for, as illustrated in FIG. 9, there is then removed a portion of the masking layer **31** to form an opening **42** therethrough immediately above the portion of the base layer **36** extending laterally from the emitter **39**. In this manner, there is provided a substantial contact area of the base layer **36** available at the upper surface of the transistor for attachment of an ohmic contact thereto. Please note in this respect that the mask **31** is not removed from the upper surface of the transistor above the emitter-base junction **41**, but instead is retained thereat so as to protect this junction from inadvertent shorting or other damage during subsequent manufacturing and handling operations. Not only is this junction **41** covered at the above-noted points, but additionally it is wholly encased by the oxide layer **31** at all other points upon the upper surface of the wafer. Likewise, the base-collector junction **37** is fully covered by the oxide layer **31** atop the transistor. As a consequence of this structure, there is provided a materially improved transistor structure wherein inadvertent damage or shorting of the junctions thereof is wholly precluded. In a conventional manner there may then be applied ohmic contacts to the emitter, base and collector. In this respect it is herein possible to provide an ohmic contact to the collector at the upper surface thereof so as to produce a transistor having all contacts on the same side. This is herein accomplished by providing an additional opening **43** through the mask **31** in lateral separation from the base opening **42** and therefore unmasking a desired extent of the collector at the top thereof. Ohmic contacts **44**, **46** and **47** are then applied in a relatively conventional manner to the separate portions of the transistor through the openings **33**, **42** and **43**. It is herein possible to employ conventional plating techniques to apply electrical conductors to the semiconductor. Inasmuch as the transistor junctions are entirely covered and protected upon the upper surface of the transistor, no possible eletcrical shorting or damage to junctions can result from plating or alloying processes.

6

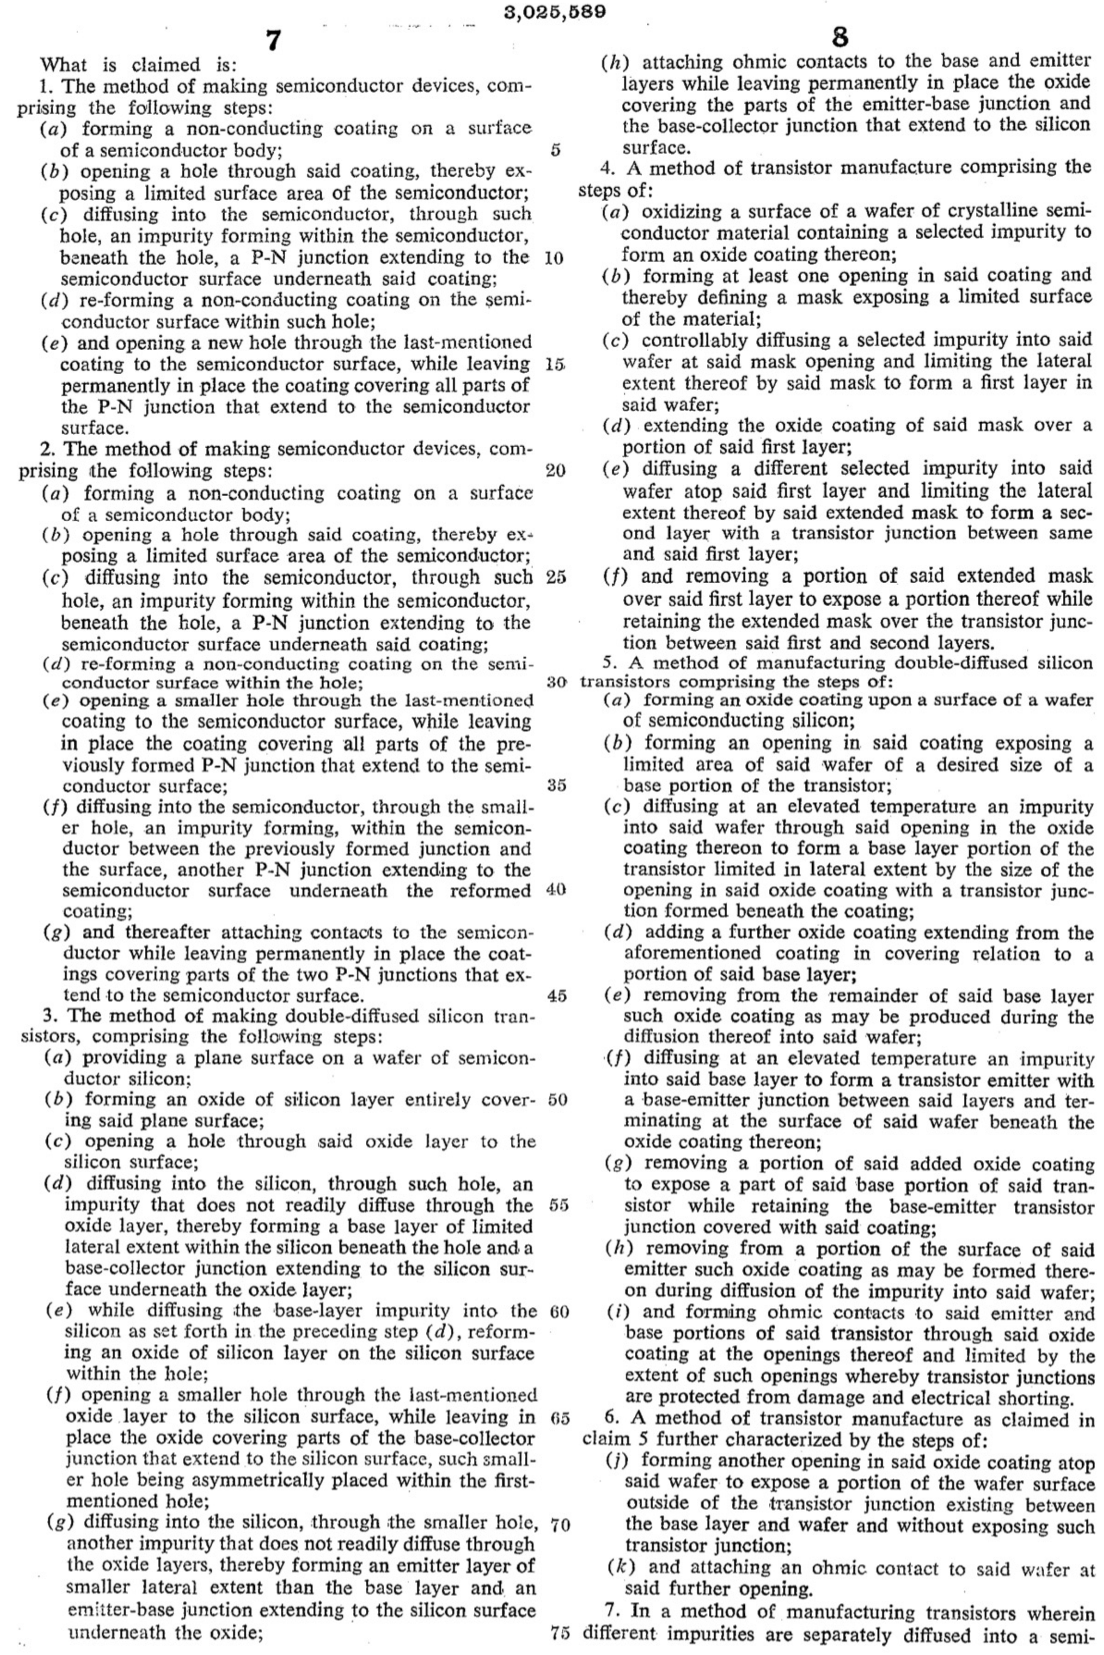
It will of course be appreciated that the silicon oxide herein stated as comprising the masking layer **31** upon the transistor wafer **32** does not react with the impurity employed in the formation of different type semiconducting materials. In this respect particular care must be taken to exclude gallium as a suitable impurity from the group III elements that may be diffused into the silicon, for this particular element does react with silicon oxide and consequently the mask will not be effective to limit the lateral extent of the diffusion of the impurity. Substantially all of the impurities which are desirable for use as dopants or diffusing elements with silicon do not react with the oxide layer herein employed, and consequently the method of the present invention is only limited insofar as the element gallium is concerned.

It is further noted that in the process above described relating to the manufacture of a triode transistor of a double-diffused silicon type, any unavoidable production of an oxide layer upon the upper surface of the wafer at points wherein the same is not desired is followed by the removal of same. Thus, for example, following the production of the base layer **36** by diffusing the selected impurity into the wafer **32**, there may result a thin oxide layer over the top of the base portion of the transistor and this layer is then removed, at least in part, as by etching or photoresist techniques.

Considering now the improved double-diffused silicon transistor of the present invention, reference is made to FIG. 10 of the drawing where there is illustrated in cross-section such a transistor. As may be seen from this this figure, the improved transistor includes a collector disc or wafer **32**, formed for example, of an N-type silicon. At the top of this collector wafer **32** there is disposed a thin base layer **36**, formed of silicon of opposite conductive type, thus in the present example of P-type silicon. Atop the base layer **36** there is provided an emitter layer or dot **39**, of N-type silicon, and having a very minute dimension. Although not previously discussed, the present invention is particularly adapted to high frequency applications wherein very small dimensions are required of the transistor portions. Thus, in the present invention, the lateral extent of the emitter may be substantially less than one millimeter and the thickness of the base layer between emitter and collector may be of the order of one micron. Upon the upper surface of the wafer **32** there is provided the oxide layer or coating **31** which will be seen to fully cover both the emitter-base junction **41** and the base-collector junction **37**. Openings **33**, **42** and **43** through this oxide coating **31** provide communication with the emitter, base and collector, respectively, of the transistor whereby ohmic contacts may be made all in the upper plane of the transistor. Thus an ohmic contact including an electrical lead **44** is provided atop the emitter **39**, while a second ohmic contact including a lead **46** is provided in connection with the upper surface of the base **36** through the masked openings **42**. Likewise, a third ohmic contact **47** including an electrical conductor, is electrically and mechanically joined to the upper surface of the collector wafer **32** through the mask opening **43**. The resulting transistor structure illustrated in FIG. 10 of the drawing will be seen to be particularly well adapted for high frequency applications, and furthermore to be fully protected from shorting of the junctions thereof as may otherwise occur during manufacture. While this transistor structure is well adapted to the provision of an ohmic contact to the collector thereof at the common upper surface of the transistor, yet the collector contact may also be provided upon the under surface of the wafer **32** as in the manner of the diode manufacture described above.

Although the above description of both the manufacturing process and the transistor structure has been referenced to an NPN transistor, it will be appreciated that it is equally applicable to PNP type transistors.

Figure B.170: Jean Hoerni invented methods of manufacturing silicon transistors.



What is claimed is:

1. The method of making semiconductor devices, comprising the following steps:
(*a*) forming a non-conducting coating on a surface of a semiconductor body;
(*b*) opening a hole through said coating, thereby exposing a limited surface area of the semiconductor;
(*c*) diffusing into the semiconductor, through such hole, an impurity forming within the semiconductor, beneath the hole, a P-N junction extending to the semiconductor surface underneath said coating;
(*d*) re-forming a non-conducting coating on the semiconductor surface within such hole;
(*e*) and opening a new hole through the last-mentioned coating to the semiconductor surface, while leaving permanently in place the coating covering all parts of the P-N junction that extend to the semiconductor surface.

2. The method of making semiconductor devices, comprising the following steps:
(*a*) forming a non-conducting coating on a surface of a semiconductor body;
(*b*) opening a hole through said coating, thereby exposing a limited surface area of the semiconductor;
(*c*) diffusing into the semiconductor, through such hole, an impurity forming within the semiconductor, beneath the hole, a P-N junction extending to the semiconductor surface underneath said coating;
(*d*) re-forming a non-conducting coating on the semiconductor surface within the hole;
(*e*) opening a smaller hole through the last-mentioned coating to the semiconductor surface, while leaving in place the coating covering all parts of the previously formed P-N junction that extend to the semiconductor surface;
(*f*) diffusing into the semiconductor, through the smaller hole, an impurity forming, within the semiconductor between the previously formed junction and the surface, another P-N junction extending to the semiconductor surface underneath the reformed coating;
(*g*) and thereafter attaching contacts to the semiconductor while leaving permanently in place the coatings covering parts of the two P-N junctions that extend to the semiconductor surface.

3. The method of making double-diffused silicon transistors, comprising the following steps:
(*a*) providing a plane surface on a wafer of semiconductor silicon;
(*b*) forming an oxide of silicon layer entirely covering said plane surface;
(*c*) opening a hole through said oxide layer to the silicon surface;
(*d*) diffusing into the silicon, through such hole, an impurity that does not readily diffuse through the oxide layer, thereby forming a base layer of limited lateral extent within the silicon beneath the hole and a base-collector junction extending to the silicon surface underneath the oxide layer;
(*e*) while diffusing the base-layer impurity into the silicon as set forth in the preceding step (*d*), reforming an oxide of silicon layer on the silicon surface within the hole;
(*f*) opening a smaller hole through the last-mentioned oxide layer to the silicon surface, while leaving in place the oxide covering parts of the base-collector junction that extend to the silicon surface, such smaller hole being asymmetrically placed within the first-mentioned hole;
(*g*) diffusing into the silicon, through the smaller hole, another impurity that does not readily diffuse through the oxide layers, thereby forming an emitter layer of smaller lateral extent than the base layer and an emitter-base junction extending to the silicon surface underneath the oxide;
(*h*) attaching ohmic contacts to the base and emitter layers while leaving permanently in place the oxide covering the parts of the emitter-base junction and the base-collector junction that extend to the silicon surface.

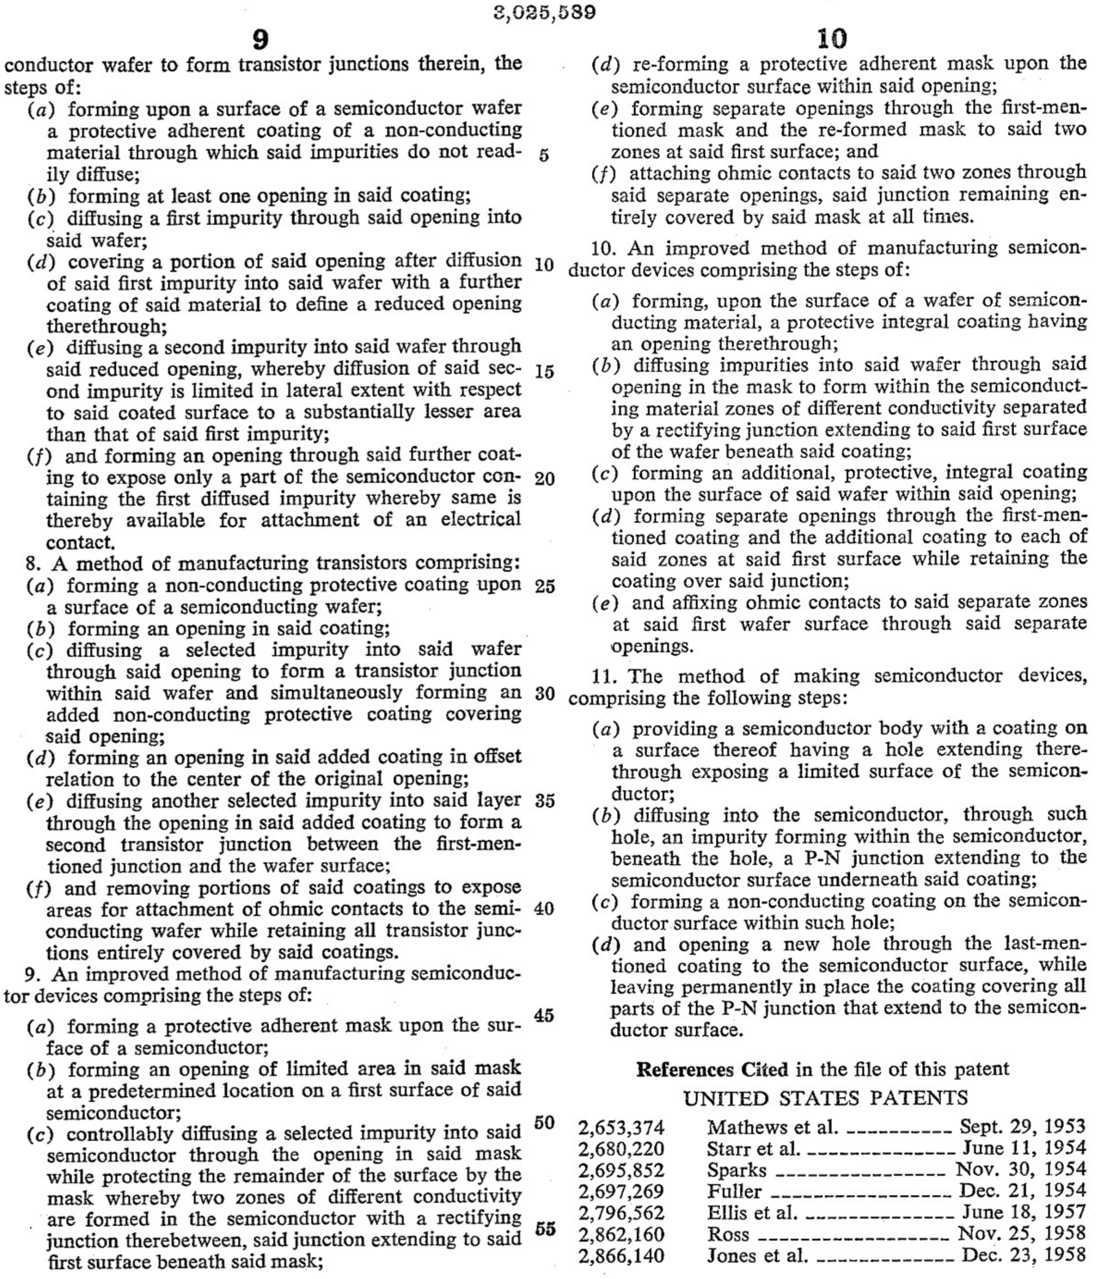
4. A method of transistor manufacture comprising the steps of:
(*a*) oxidizing a surface of a wafer of crystalline semiconductor material containing a selected impurity to form an oxide coating thereon;
(*b*) forming at least one opening in said coating and thereby defining a mask exposing a limited surface of the material;
(*c*) controllably diffusing a selected impurity into said wafer at said mask opening and limiting the lateral extent thereof by said mask to form a first layer in said wafer;
(*d*) extending the oxide coating of said mask over a portion of said first layer;
(*e*) diffusing a different selected impurity into said wafer atop said first layer and limiting the lateral extent thereof by said extended mask to form a second layer with a transistor junction between same and said first layer;
(*f*) and removing a portion of said extended mask over said first layer to expose a portion thereof while retaining the extended mask over the transistor junction between said first and second layers.

5. A method of manufacturing double-diffused silicon transistors comprising the steps of:
(*a*) forming an oxide coating upon a surface of a wafer of semiconducting silicon;
(*b*) forming an opening in said coating exposing a limited area of said wafer of a desired size of a base portion of the transistor;
(*c*) diffusing at an elevated temperature an impurity into said wafer through said opening in the oxide coating thereon to form a base layer portion of the transistor limited in lateral extent by the size of the opening in said oxide coating with a transistor junction formed beneath the coating;
(*d*) adding a further oxide coating extending from the aforementioned coating in covering relation to a portion of said base layer;
(*e*) removing from the remainder of said base layer such oxide coating as may be produced during the diffusion thereof into said wafer;
(*f*) diffusing at an elevated temperature an impurity into said base layer to form a transistor emitter with a base-emitter junction between said layers and terminating at the surface of said wafer beneath the oxide coating thereon;
(*g*) removing a portion of said added oxide coating to expose a part of said base portion of said transistor while retaining the base-emitter transistor junction covered with said coating;
(*h*) removing from a portion of the surface of said emitter such oxide coating as may be formed thereon during diffusion of the impurity into said wafer;
(*i*) and forming ohmic contacts to said emitter and base portions of said transistor through said oxide coating at the openings thereof and limited by the extent of such openings whereby transistor junctions are protected from damage and electrical shorting.

6. A method of transistor manufacture as claimed in claim 5 further characterized by the steps of:
(*j*) forming another opening in said oxide coating atop said wafer to expose a portion of the wafer surface outside of the transistor junction existing between the base layer and wafer and without exposing such transistor junction;
(*k*) and attaching an ohmic contact to said wafer at said further opening.

7. In a method of manufacturing transistors wherein different impurities are separately diffused into a semi-

Figure B.171: Jean Hoerni invented methods of manufacturing silicon transistors.



3,025,589

9

conductor wafer to form transistor junctions therein, the steps of:

(*a*) forming upon a surface of a semiconductor wafer a protective adherent coating of a non-conducting material through which said impurities do not readily diffuse;
(*b*) forming at least one opening in said coating;
(*c*) diffusing a first impurity through said opening into said wafer;
(*d*) covering a portion of said opening after diffusion of said first impurity into said wafer with a further coating of said material to define a reduced opening therethrough;
(*e*) diffusing a second impurity into said wafer through said reduced opening, whereby diffusion of said second impurity is limited in lateral extent with respect to said coated surface to a substantially lesser area than that of said first impurity;
(*f*) and forming an opening through said further coating to expose only a part of the semiconductor containing the first diffused impurity whereby same is thereby available for attachment of an electrical contact.

8. A method of manufacturing transistors comprising:

(*a*) forming a non-conducting protective coating upon a surface of a semiconducting wafer;
(*b*) forming an opening in said coating;
(*c*) diffusing a selected impurity into said wafer through said opening to form a transistor junction within said wafer and simultaneously forming an added non-conducting protective coating covering said opening;
(*d*) forming an opening in said added coating in offset relation to the center of the original opening;
(*e*) diffusing another selected impurity into said layer through the opening in said added coating to form a second transistor junction between the first-mentioned junction and the wafer surface;
(*f*) and removing portions of said coatings to expose areas for attachment of ohmic contacts to the semiconducting wafer while retaining all transistor junctions entirely covered by said coatings.

9. An improved method of manufacturing semiconductor devices comprising the steps of:

(*a*) forming a protective adherent mask upon the surface of a semiconductor;
(*b*) forming an opening of limited area in said mask at a predetermined location on a first surface of said semiconductor;
(*c*) controllably diffusing a selected impurity into said semiconductor through the opening in said mask while protecting the remainder of the surface by the mask whereby two zones of different conductivity are formed in the semiconductor with a rectifying junction therebetween, said junction extending to said first surface beneath said mask;

10

(*d*) re-forming a protective adherent mask upon the semiconductor surface within said opening;
(*e*) forming separate openings through the first-mentioned mask and the re-formed mask to said two zones at said first surface; and
(*f*) attaching ohmic contacts to said two zones through said separate openings, said junction remaining entirely covered by said mask at all times.

10. An improved method of manufacturing semiconductor devices comprising the steps of:

(*a*) forming, upon the surface of a wafer of semiconducting material, a protective integral coating having an opening therethrough;
(*b*) diffusing impurities into said wafer through said opening in the mask to form within the semiconducting material zones of different conductivity separated by a rectifying junction extending to said first surface of the wafer beneath said coating;
(*c*) forming an additional, protective, integral coating upon the surface of said wafer within said opening;
(*d*) forming separate openings through the first-mentioned coating and the additional coating to each of said zones at said first surface while retaining the coating over said junction;
(*e*) and affixing ohmic contacts to said separate zones at said first wafer surface through said separate openings.

11. The method of making semiconductor devices, comprising the following steps:

(*a*) providing a semiconductor body with a coating on a surface thereof having a hole extending therethrough exposing a limited surface of the semiconductor;
(*b*) diffusing into the semiconductor, through such hole, an impurity forming within the semiconductor, beneath the hole, a P-N junction extending to the semiconductor surface underneath said coating;
(*c*) forming a non-conducting coating on the semiconductor surface within such hole;
(*d*) and opening a new hole through the last-mentioned coating to the semiconductor surface, while leaving permanently in place the coating covering all parts of the P-N junction that extend to the semiconductor surface.

SEMICONDUCTOR DEVICE

Jean A. Hoerni, Los Altos, Calif., assignor, by mesne assignments, to Fairchild Camera and Instrument Corporation, Syosset, N.Y., a corporation of Delaware
Original application May 1, 1959, Ser. No. 810,388. Divided and this application May 19, 1960, Ser. No. 30,256
6 Claims. (Cl. 317—234)

This application is a division of my copending application Serial No. 810,388, filed May 1, 1959, and now Patent No. 3,025,589.

The present invention relates to an improvement in semiconductor devices including transistors and to an improved transistor structure. More particularly, the invention relates to an improved diffusion transistor having fully protected junctions and maximized exposed surfaces for ohmic contact attachment.

Advancements in transistor technology have in part been directed to the production of very small sized transistor structures, inasmuch as minute semiconductor geometries are required for high frequency applications of transistors. While the well known point-contact transistor is adapted for high frequency work, yet certain limitations attach to this type of transistor and consequently junction transistors have been developed for use in the high frequency range. One type of junction transistor which is particularly well adapted for high frequency applications is the double-diffused silicon transistor, and although the present invention is adapted for use with other types of transistors it is with respect to double-diffused silicon transistors that the following description is referenced.

As regards the manufacture of double-diffused silicon transistors, and in fact any minute transistor structure, difficulty is encountered in providing a sufficient exposed area of the base material for attachment of an ohmic contact thereto. By maintaining the extremely small element dimensions required of the transistor, there results only a minute thickness of base material exposed between the base-collector junction and the emitter-base junction on a transistor surface. Conventional transistor utility requires the provision of electrical contacts to the individual transistor elements or portions, and thus it is necessary for the dimensions of the base portion to be made sufficient to attach such contacts. In certain instances this limitation upon the size of the base portion is highly undesirable, inasmuch as conventional manufacturing practices produce a base thickness in proportion to the exposed base width.

Another difficulty arising from the limited size necessary for transistors to suitably operate at very high frequencies is encountered in the difficulty of protecting the transistor junction. This is particularly noted in the attachment of electrical contacts to the transistor portions inasmuch as very minute variations in the placement of electrical conductors or ohmic contacts to the transistor may well result in electrically shorting of the transistor junction, whereby the transistor structure is unsuited for use and must be rejected. This latter problem is compounded by the necessity in high-frequency transistors of employing an ohmic contact which substantially entirely covers the exposed surface of each of the elements in order to minimize the spreading resistance thereof. Conventional plating methods are unsuited for the provision of such ohmic contacts to within fractions of a millimeter from the transistor junction, as is normally required for transistor structures capable of operating at very high frequencies. Not only is the problem of providing suitable ohmic contacts to the transistor portions a major one, but also the possible damage or other types of inadvertent electrical shorting of the transistor junctions during manufacturing processes is of major importance in limiting the number of rejects in any manufacturing process. Additionally, long range contamination of transistor junctions may be a cause of drifting and deterioration of transistor characteristics.

2

There have been developed for high frequency applications transistors of the "mesa" design wherein undesirable lateral extensions of the base-collector junction are removed by etching to produce transistors of very small dimensions. Although mesa transistors have found wide acceptance in the art, the junction exposed by the etching, as well as the other junction, is particularly vulnerable to contamination or degradation during subsequent portions of the manufacturing process. In accordance with the present invention there is produced a transistor having the minute dimensions of the mesa type, but with the transistor junctions at all times fully protected by an oxide layer or coating formed simultaneously with the junction during diffusion at high temperatures so that no contamination of the transistor junctions during or after manufacture is possible. In this manner, one of the major causes of transistor failure is entirely precluded.

It is an object of the present invention to provide an improved semiconducting device having a protective coating thereover except for ohmic contact areas.

It is a still further object of the present invention to provide an improved transistor structure having a laterally extended base surface for ohmic contact thereto, and including covered junction and exposed transistor surfaces.

Various other possible objects and advantages of the present invention will become apparent to those skilled in the art from the following description of the present invention. Although the invention is herein illustrated with respect to particular preferred embodiments thereof, no limitation is intended thereby, and reference is made to the appended claims for a precise delineation of the true scope of the present invention.

The present invention is particularly well adapted to diode units as well as multi-element units. Although the problems encountered in high frequency triode transistors are normally more troublesome than those found in the diode art, yet the present invention provides material advantage diode semiconductors. Furthermore, although as previously noted, the present invention may be employed with a variety of semiconducting materials, yet actual use thereof has been primarily directed to silicon transistors and thus the following description is referenced thereto.

The invention is illustrated in the accompanying drawings wherein:

FIG. 1 is a plan view of a wafer of semiconducting material having the masking layer thereof removed within the illustrated circles;

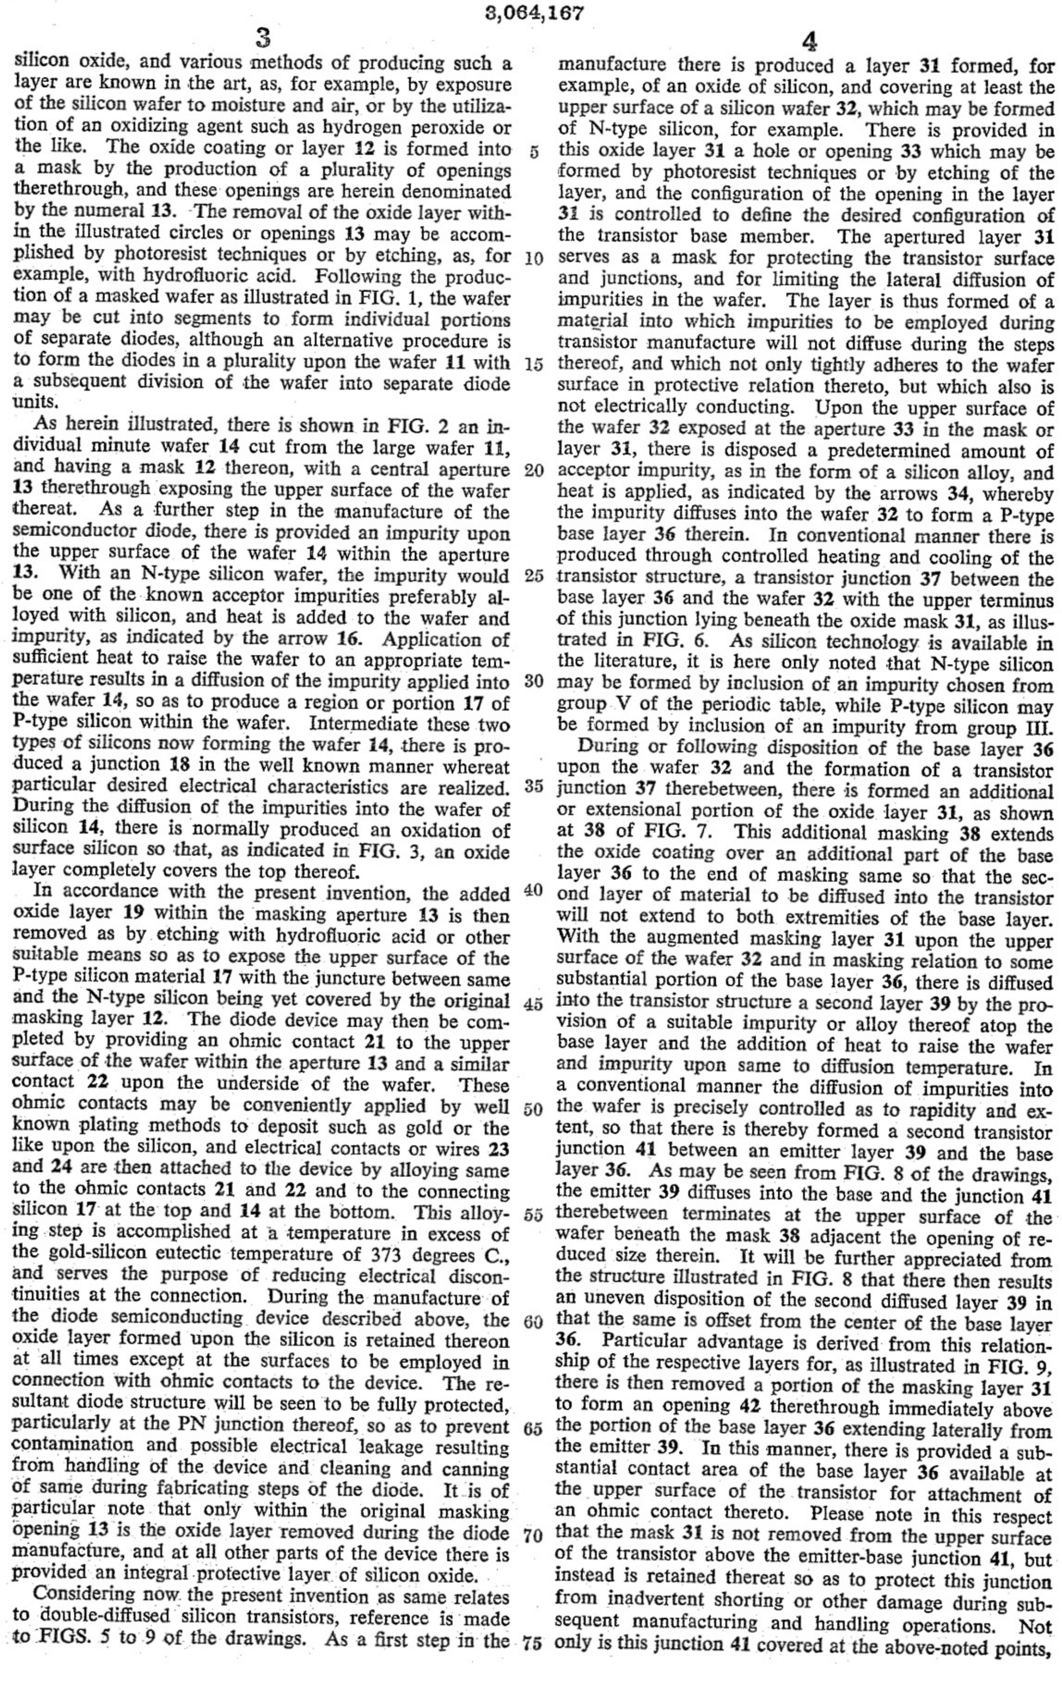
FIGS. 2, 3, and 4 are sectional views through a semiconducting diode device, at separate stages of manufacture thereof, in accordance with the present invention;

FIGS. 5, 6, 7, 8 and 9 are sectional views through a triode semiconducting device or transistor, showing same at separate stages of manufacture, in accordance with the present invention; and

FIG. 10 is a sectional view through a transistor in accordance with the present invention.

Reference is made to FIGS. 1 to 4, wherein there is illustrated a diode semiconducting device, at various stages of manufacture thereof, in accordance with the present invention. There is illustrated in FIG. 1 a wafer **11** formed of a semiconducting material such as silicon having, for example, an N-type impurity therein. This wafer **11** has formed thereon as a step of the present invention, a coating **12** entirely covering the upper surface of the wafer. Preferably, this coating is formed of a

Figure B.174: Jean Hoerni invented methods of manufacturing silicon transistors.



silicon oxide, and various methods of producing such a layer are known in the art, as, for example, by exposure of the silicon wafer to moisture and air, or by the utilization of an oxidizing agent such as hydrogen peroxide or the like. The oxide coating or layer **12** is formed into a mask by the production of a plurality of openings therethrough, and these openings are herein denominated by the numeral **13**. The removal of the oxide layer within the illustrated circles or openings **13** may be accomplished by photoresist techniques or by etching, as, for example, with hydrofluoric acid. Following the production of a masked wafer as illustrated in FIG. 1, the wafer may be cut into segments to form individual portions of separate diodes, although an alternative procedure is to form the diodes in a plurality upon the wafer **11** with a subsequent division of the wafer into separate diode units.

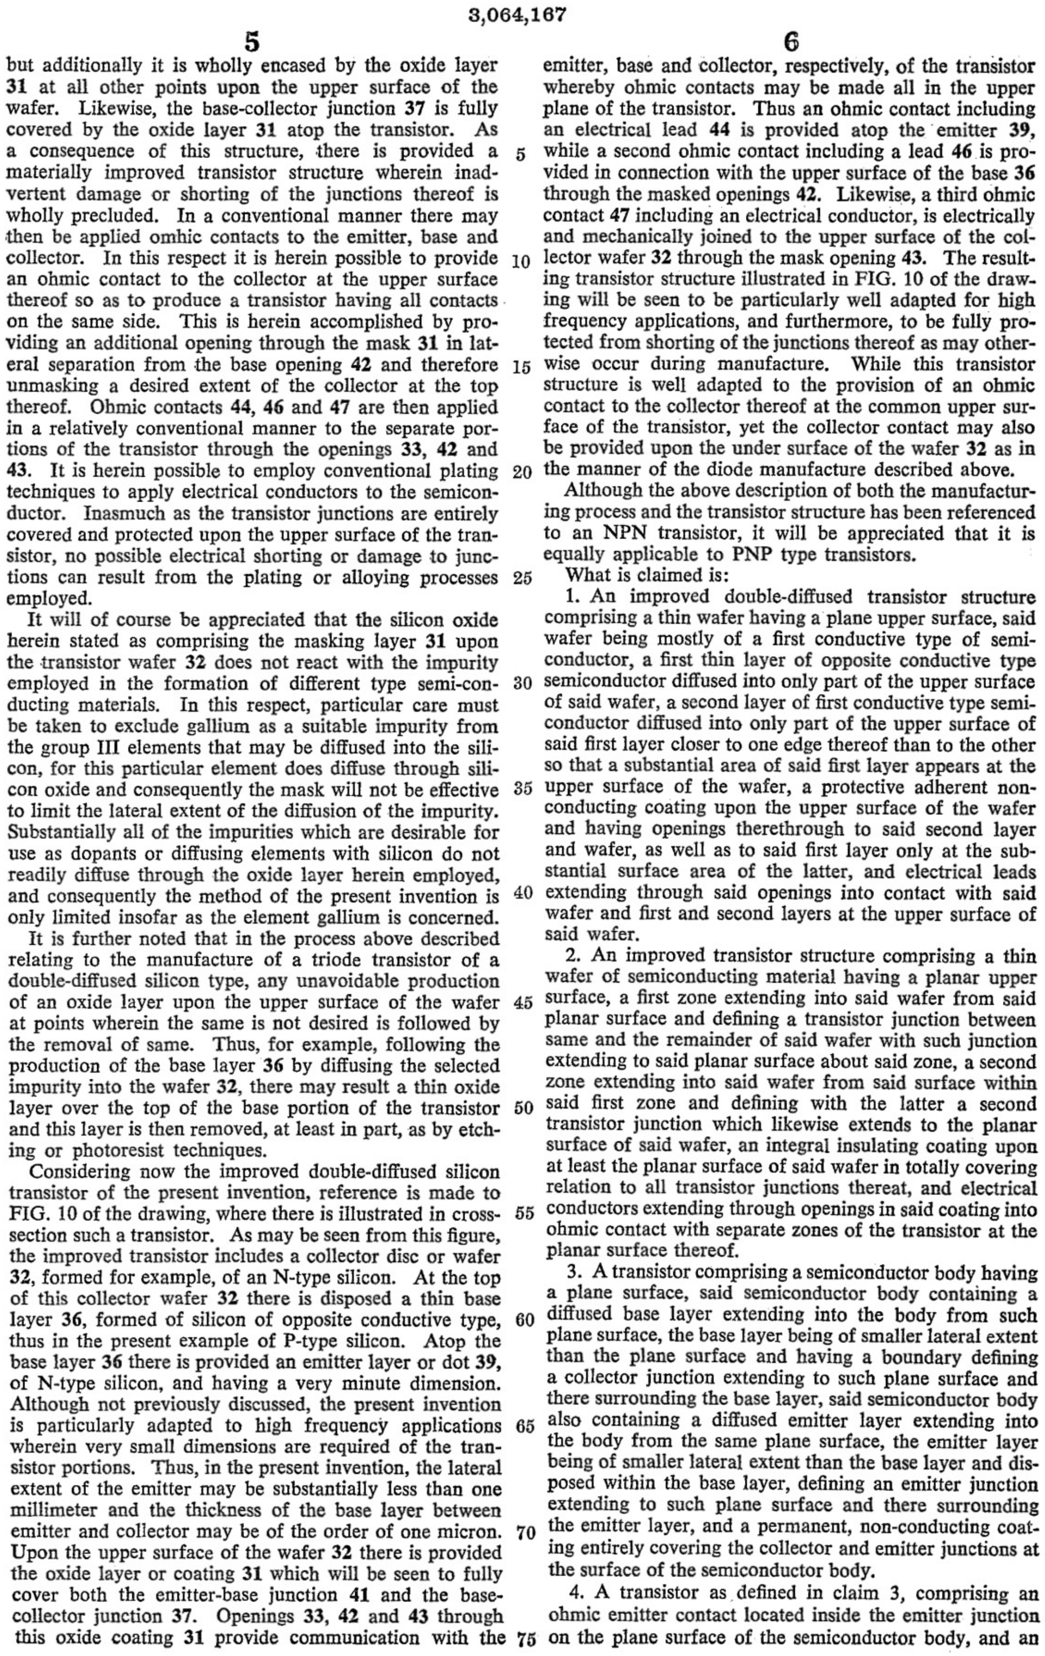
As herein illustrated, there is shown in FIG. 2 an individual minute wafer **14** cut from the large wafer **11**, and having a mask **12** thereon, with a central aperture **13** therethrough exposing the upper surface of the wafer thereat. As a further step in the manufacture of the semiconductor diode, there is provided an impurity upon the upper surface of the wafer **14** within the aperture **13**. With an N-type silicon wafer, the impurity would be one of the known acceptor impurities preferably alloyed with silicon, and heat is added to the wafer and impurity, as indicated by the arrow **16**. Application of sufficient heat to raise the wafer to an appropriate temperature results in a diffusion of the impurity applied into the wafer **14**, so as to produce a region or portion **17** of P-type silicon within the wafer. Intermediate these two types of silicons now forming the wafer **14**, there is produced a junction **18** in the well known manner whereat particular desired electrical characteristics are realized. During the diffusion of the impurities into the wafer of silicon **14**, there is normally produced an oxidation of surface silicon so that, as indicated in FIG. 3, an oxide layer completely covers the top thereof.

In accordance with the present invention, the added oxide layer **19** within the masking aperture **13** is then removed as by etching with hydrofluoric acid or other suitable means so as to expose the upper surface of the P-type silicon material **17** with the juncture between same and the N-type silicon being yet covered by the original masking layer **12**. The diode device may then be completed by providing an ohmic contact **21** to the upper surface of the wafer within the aperture **13** and a similar contact **22** upon the underside of the wafer. These ohmic contacts may be conveniently applied by well known plating methods to deposit such as gold or the like upon the silicon, and electrical contacts or wires **23** and **24** are then attached to the device by alloying same to the ohmic contacts **21** and **22** and to the connecting silicon **17** at the top and **14** at the bottom. This alloying step is accomplished at a temperature in excess of the gold-silicon eutectic temperature of 373 degrees C., and serves the purpose of reducing electrical discontinuities at the connection. During the manufacture of the diode semiconducting device described above, the oxide layer formed upon the silicon is retained thereon at all times except at the surfaces to be employed in connection with ohmic contacts to the device. The resultant diode structure will be seen to be fully protected, particularly at the PN junction thereof, so as to prevent contamination and possible electrical leakage resulting from handling of the device and cleaning and canning of same during fabricating steps of the diode. It is of particular note that only within the original masking opening **13** is the oxide layer removed during the diode manufacture, and at all other parts of the device there is provided an integral protective layer of silicon oxide.

Considering now the present invention as same relates to double-diffused silicon transistors, reference is made to FIGS. 5 to 9 of the drawings. As a first step in the manufacture there is produced a layer **31** formed, for example, of an oxide of silicon, and covering at least the upper surface of a silicon wafer **32**, which may be formed of N-type silicon, for example. There is provided in this oxide layer **31** a hole or opening **33** which may be formed by photoresist techniques or by etching of the layer, and the configuration of the opening in the layer **31** is controlled to define the desired configuration of the transistor base member. The apertured layer **31** serves as a mask for protecting the transistor surface and junctions, and for limiting the lateral diffusion of impurities in the wafer. The layer is thus formed of a material into which impurities to be employed during transistor manufacture will not diffuse during the steps thereof, and which not only tightly adheres to the wafer surface in protective relation thereto, but which also is not electrically conducting. Upon the upper surface of the wafer **32** exposed at the aperture **33** in the mask or layer **31**, there is disposed a predetermined amount of acceptor impurity, as in the form of a silicon alloy, and heat is applied, as indicated by the arrows **34**, whereby the impurity diffuses into the wafer **32** to form a P-type base layer **36** therein. In conventional manner there is produced through controlled heating and cooling of the transistor structure, a transistor junction **37** between the base layer **36** and the wafer **32** with the upper terminus of this junction lying beneath the oxide mask **31**, as illustrated in FIG. 6. As silicon technology is available in the literature, it is here only noted that N-type silicon may be formed by inclusion of an impurity chosen from group V of the periodic table, while P-type silicon may be formed by inclusion of an impurity from group III.

During or following disposition of the base layer **36** upon the wafer **32** and the formation of a transistor junction **37** therebetween, there is formed an additional or extensional portion of the oxide layer **31**, as shown at **38** of FIG. 7. This additional masking **38** extends the oxide coating over an additional part of the base layer **36** to the end of masking same so that the second layer of material to be diffused into the transistor will not extend to both extremities of the base layer. With the augmented masking layer **31** upon the upper surface of the wafer **32** and in masking relation to some substantial portion of the base layer **36**, there is diffused into the transistor structure a second layer **39** by the provision of a suitable impurity or alloy thereof atop the base layer and the addition of heat to raise the wafer and impurity upon same to diffusion temperature. In a conventional manner the diffusion of impurities into the wafer is precisely controlled as to rapidity and extent, so that there is thereby formed a second transistor junction **41** between an emitter layer **39** and the base layer **36**. As may be seen from FIG. 8 of the drawings, the emitter **39** diffuses into the base and the junction **41** therebetween terminates at the upper surface of the wafer beneath the mask **38** adjacent the opening of reduced size therein. It will be further appreciated from the structure illustrated in FIG. 8 that there then results an uneven disposition of the second diffused layer **39** in that the same is offset from the center of the base layer **36**. Particular advantage is derived from this relationship of the respective layers for, as illustrated in FIG. 9, there is then removed a portion of the masking layer **31** to form an opening **42** therethrough immediately above the portion of the base layer **36** extending laterally from the emitter **39**. In this manner, there is provided a substantial contact area of the base layer **36** available at the upper surface of the transistor for attachment of an ohmic contact thereto. Please note in this respect that the mask **31** is not removed from the upper surface of the transistor above the emitter-base junction **41**, but instead is retained thereat so as to protect this junction from inadvertent shorting or other damage during subsequent manufacturing and handling operations. Not only is this junction **41** covered at the above-noted points,

Figure B.175: Jean Hoerni invented methods of manufacturing silicon transistors.



3,064,167

5

but additionally it is wholly encased by the oxide layer **31** at all other points upon the upper surface of the wafer. Likewise, the base-collector junction **37** is fully covered by the oxide layer **31** atop the transistor. As a consequence of this structure, there is provided a materially improved transistor structure wherein inadvertent damage or shorting of the junctions thereof is wholly precluded. In a conventional manner there may then be applied omhic contacts to the emitter, base and collector. In this respect it is herein possible to provide an ohmic contact to the collector at the upper surface thereof so as to produce a transistor having all contacts on the same side. This is herein accomplished by providing an additional opening through the mask **31** in lateral separation from the base opening **42** and therefore unmasking a desired extent of the collector at the top thereof. Ohmic contacts **44**, **46** and **47** are then applied in a relatively conventional manner to the separate portions of the transistor through the openings **33**, **42** and **43**. It is herein possible to employ conventional plating techniques to apply electrical conductors to the semiconductor. Inasmuch as the transistor junctions are entirely covered and protected upon the upper surface of the transistor, no possible electrical shorting or damage to junctions can result from the plating or alloying processes employed.

It will of course be appreciated that the silicon oxide herein stated as comprising the masking layer **31** upon the transistor wafer **32** does not react with the impurity employed in the formation of different type semi-conducting materials. In this respect, particular care must be taken to exclude gallium as a suitable impurity from the group III elements that may be diffused into the silicon, for this particular element does diffuse through silicon oxide and consequently the mask will not be effective to limit the lateral extent of the diffusion of the impurity. Substantially all of the impurities which are desirable for use as dopants or diffusing elements with silicon do not readily diffuse through the oxide layer herein employed, and consequently the method of the present invention is only limited insofar as the element gallium is concerned.

It is further noted that in the process above described relating to the manufacture of a triode transistor of a double-diffused silicon type, any unavoidable production of an oxide layer upon the upper surface of the wafer at points wherein the same is not desired is followed by the removal of same. Thus, for example, following the production of the base layer **36** by diffusing the selected impurity into the wafer **32**, there may result a thin oxide layer over the top of the base portion of the transistor and this layer is then removed, at least in part, as by etching or photoresist techniques.

Considering now the improved double-diffused silicon transistor of the present invention, reference is made to FIG. 10 of the drawing, where there is illustrated in cross-section such a transistor. As may be seen from this figure, the improved transistor includes a collector disc or wafer **32**, formed for example, of an N-type silicon. At the top of this collector wafer **32** there is disposed a thin base layer **36**, formed of silicon of opposite conductive type, thus in the present example of P-type silicon. Atop the base layer **36** there is provided an emitter layer or dot **39**, of N-type silicon, and having a very minute dimension. Although not previously discussed, the present invention is particularly adapted to high frequency applications wherein very small dimensions are required of the transistor portions. Thus, in the present invention, the lateral extent of the emitter may be substantially less than one millimeter and the thickness of the base layer between emitter and collector may be of the order of one micron. Upon the upper surface of the wafer **32** there is provided the oxide layer or coating **31** which will be seen to fully cover both the emitter-base junction **41** and the base-collector junction **37**. Openings **33**, **42** and **43** through this oxide coating **31** provide communication with the

6

emitter, base and collector, respectively, of the transistor whereby ohmic contacts may be made all in the upper plane of the transistor. Thus an ohmic contact including an electrical lead **44** is provided atop the emitter **39**, while a second ohmic contact including a lead **46** is provided in connection with the upper surface of the base **36** through the masked openings **42**. Likewise, a third ohmic contact **47** including an electrical conductor, is electrically and mechanically joined to the upper surface of the collector wafer **32** through the mask opening **43**. The resulting transistor structure illustrated in FIG. 10 of the drawing will be seen to be particularly well adapted for high frequency applications, and furthermore, to be fully protected from shorting of the junctions thereof as may otherwise occur during manufacture. While this transistor structure is well adapted to the provision of an ohmic contact to the collector thereof at the common upper surface of the transistor, yet the collector contact may also be provided upon the under surface of the wafer **32** as in the manner of the diode manufacture described above.

Although the above description of both the manufacturing process and the transistor structure has been referenced to an NPN transistor, it will be appreciated that it is equally applicable to PNP type transistors.

What is claimed is:

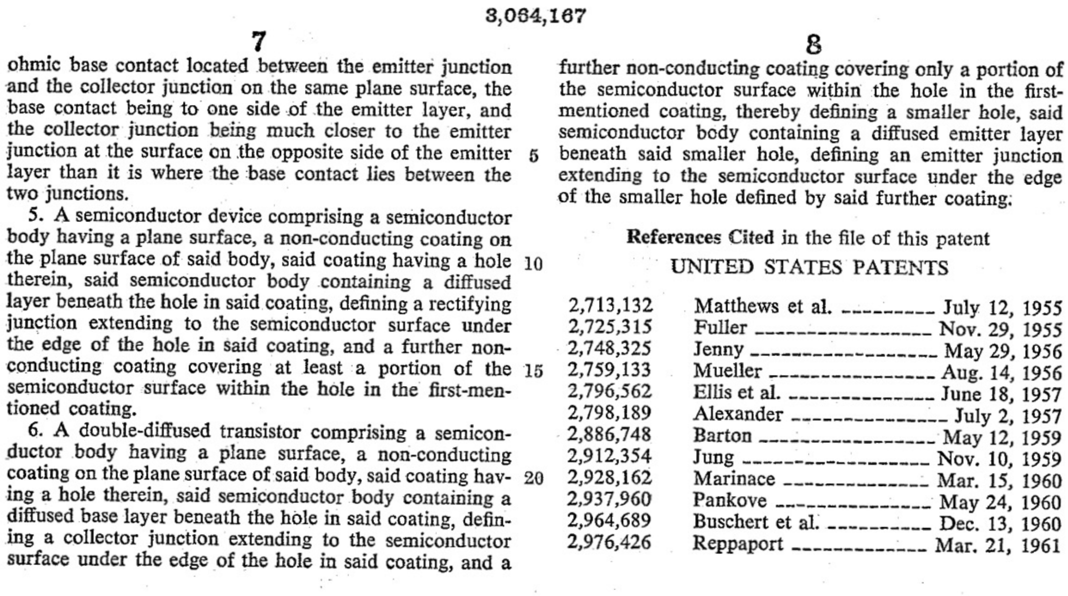
1. An improved double-diffused transistor structure comprising a thin wafer having a plane upper surface, said wafer being mostly of a first conductive type of semiconductor, a first thin layer of opposite conductive type semiconductor diffused into only part of the upper surface of said wafer, a second layer of first conductive type semiconductor diffused into only part of the upper surface of said first layer closer to one edge thereof than to the other so that a substantial area of said first layer appears at the upper surface of the wafer, a protective adherent nonconducting coating upon the upper surface of the wafer and having openings therethrough to said second layer and wafer, as well as to said first layer only at the substantial surface area of the latter, and electrical leads extending through said openings into contact with said wafer and first and second layers at the upper surface of said wafer.

2. An improved transistor structure comprising a thin wafer of semiconducting material having a planar upper surface, a first zone extending into said wafer from said planar surface and defining a transistor junction between same and the remainder of said wafer with such junction extending to said planar surface about said zone, a second zone extending into said wafer from said surface within said first zone and defining with the latter a second transistor junction which likewise extends to the planar surface of said wafer, an integral insulating coating upon at least the planar surface of said wafer in totally covering relation to all transistor junctions thereat, and electrical conductors extending through openings in said coating into ohmic contact with separate zones of the transistor at the planar surface thereof.

3. A transistor comprising a semiconductor body having a plane surface, said semiconductor body containing a diffused base layer extending into the body from such plane surface, the base layer being of smaller lateral extent than the plane surface and having a boundary defining a collector junction extending to such plane surface and there surrounding the base layer, said semiconductor body also containing a diffused emitter layer extending into the body from the same plane surface, the emitter layer being of smaller lateral extent than the base layer and disposed within the base layer, defining an emitter junction extending to such plane surface and there surrounding the emitter layer, and a permanent, non-conducting coating entirely covering the collector and emitter junctions at the surface of the semiconductor body.

4. A transistor as defined in claim 3, comprising an ohmic emitter contact located inside the emitter junction on the plane surface of the semiconductor body, and an

Figure B.176: Jean Hoerni invented methods of manufacturing silicon transistors.



ohmic base contact located between the emitter junction and the collector junction on the same plane surface, the base contact being to one side of the emitter layer, and the collector junction being much closer to the emitter junction at the surface on the opposite side of the emitter layer than it is where the base contact lies between the two junctions.

5. A semiconductor device comprising a semiconductor body having a plane surface, a non-conducting coating on the plane surface of said body, said coating having a hole therein, said semiconductor body containing a diffused layer beneath the hole in said coating, defining a rectifying junction extending to the semiconductor surface under the edge of the hole in said coating, and a further non-conducting coating covering at least a portion of the semiconductor surface within the hole in the first-mentioned coating.

6. A double-diffused transistor comprising a semiconductor body having a plane surface, a non-conducting coating on the plane surface of said body, said coating having a hole therein, said semiconductor body containing a diffused base layer beneath the hole in said coating, defining a collector junction extending to the semiconductor surface under the edge of the hole in said coating, and a further non-conducting coating covering only a portion of the semiconductor surface within the hole in the first-mentioned coating, thereby defining a smaller hole, said semiconductor body containing a diffused emitter layer beneath said smaller hole, defining an emitter junction extending to the semiconductor surface under the edge of the smaller hole defined by said further coating.

TRANSISTOR MANUFACTURING PROCESS
Jean A. Hoerni, Los Altos, Calif., assignor, by mesne assignments, to Fairchild Camera and Instrument Corporation, Syosset, N.Y., a corporation of Delaware
Filed June 30, 1959, Ser. No. 823,954
8 Claims. (Cl. 148—186)

The present invention relates in general to the provision of a manufacturing process for semiconducting devices and more particularly to a process for improving the electrical characteristics of diode semiconductors and transistors to the end of establishing therein more sharply varying current-voltage characteristics.

The process of this invention contemplates the addition of a few simple steps in the manufacture or fabrication of semiconducting devices such as diodes and transistors, and includes the controlled addition to the semiconducting material of a selected metal impurity. Although it is common practice in the transistor art to controllably add impurities to the basic material, such as germanium or silicon, these impurities are normally designed to fulfill more obvious functions. In particular, it is conventional to diffuse selected impurities into silicon, for example, in order to produce transistor junctions within the material and a great body of art has arisen covering the manners and means for accomplishing the controlled addition of such impurities. It is also known that certain impurities may be added in controlled quantities to increase the lifetime of transistor carriers. Research in this latter field has indicated that nickel is highly desirable as an additive to improve the carrier lifetime, while certain other metals such as gold are highly undesirable in this respect. While great effort has been expended in certain aspects of the problems involved in controlling semiconductor characteristics by the addition of impurities with marked advancements resulting therefrom, certain other aspects of the problem have not been so treated. Thus, while it is possible to postulate the possible and desirable current-voltage relationship of a diode semiconductor, for example, it has been found that actual diodes tend to materially deviate therefrom, at least in certain aspects.

As regards diode semiconductors, it has been found that reverse breakdown voltage-current relationships tend not to vary sharply, as is desired for switching applications of these devices. To the contrary, many diodes exhibit gradually varying reverse breakdown characteristics and such diodes have been denominated as "soft diodes." This departure of actually manufactured diode structures from the desired characteristics thereof is quite substantial and often serves to materially limit applicability of the devices. For example, the reverse current flow at a particular value of reverse voltage for a commercially available semiconducting diode has been measured at 20 milliamperes as contrasted to a desired and expected current amplitude of 0.001 microamperes. It will be seen that the actual diode falls short of the theoretically predicted diode characteristics by a very large factor. The process of the present invention is directed to the production of diode semiconductors having the desired predicted reverse current-voltage relationships.

In the manufacture of transistors of three and more elements it has been likewise found that the variation of current with the voltage often assumes a relatively "soft" characteristic, wherein a gradual current variation with increased voltage results rather than an abrupt change, as may be desired. Specifically, as regards transistors, the collector current is often found to increase in a gradual and relatively uniform relationship with increased collector voltage, rather than the sharp current

2

increase desired at a particular value of collector voltage. The present invention is directed to the production of transistors having sharply varying electrical characteristics of the type more nearly following the predictable and desired current-voltage characteristics.

Although the above-noted characteristics of "soft diodes" and the similar characteristics of transistors have been recognized by many workers in the field, the difficulties of solid state analysis have to date effectively limited desired improvements therein. Theoretical approaches to solid state physics have proven quite difficult and, furthermore, complete and satisfactory analysis of solid state devices is also sufficiently difficult to seriously hamper full and complete understanding of the true causes of observed phenomenon. It has been postuated that certain undesirable electrical characteristics of semiconducting devices may be caused by the presence of particular impurities in the semiconducting material, or that such characteristics may be in part due to certain crystal lattice structures or imperfections. Various evidence is available to support different theories in this respect, however, it is well known that conventional manufacturing techniques produce many semiconducting devices which have certain of the electrical characteristics thereof wholly unsuited to particular applications of the device, while at the same time certain other semiconducting devices produced by the same or like process may have the desired electrical characteristics.

Although it is not herein intended to postulate a new theory of solid state physics which is basically adapted to provide theoretical solutions to presently existing problems, there is herein provided a manufacturing process which provides a highly desirable improvement in transistor characteristics. The process hereof actually relates to an addition to normal and conventional transistor manufacturing processes. Only very simple and inexpensive operations are required to carry out the process of this invention, and the same are readily adapted for inclusion in conventional transistor manufacturing methods. In accordance herewith there is controllably diffused into the semiconducting material of a device such as a transistor, a limited amount of a particular metal which serves to materially vary the electrical characteristics of the material so processed. In distinction to previous impurity diffusion processes, the materials herein suited for diffusion include the so-called "deep level impurities," such being defined in the literature. Gold and nickel are embraced by the foregoing definition. While it is true that nickel has been previously employed for diffusion into semiconducting materials for reasons wholly different from the present invention, it is widely accepted that the diffusion of gold into semiconducting material is highly deleterious, inasmuch as gold impurities tend to materially reduce the carrier lifetime. Various other of the deep level impurities are likewise generally considered to be unacceptable as impurities in even minute amounts in semiconducting material because of various deleterious effects attributable thereto.

It is an object of the present invention to provide an improved process of manufacturing semiconducting devices.

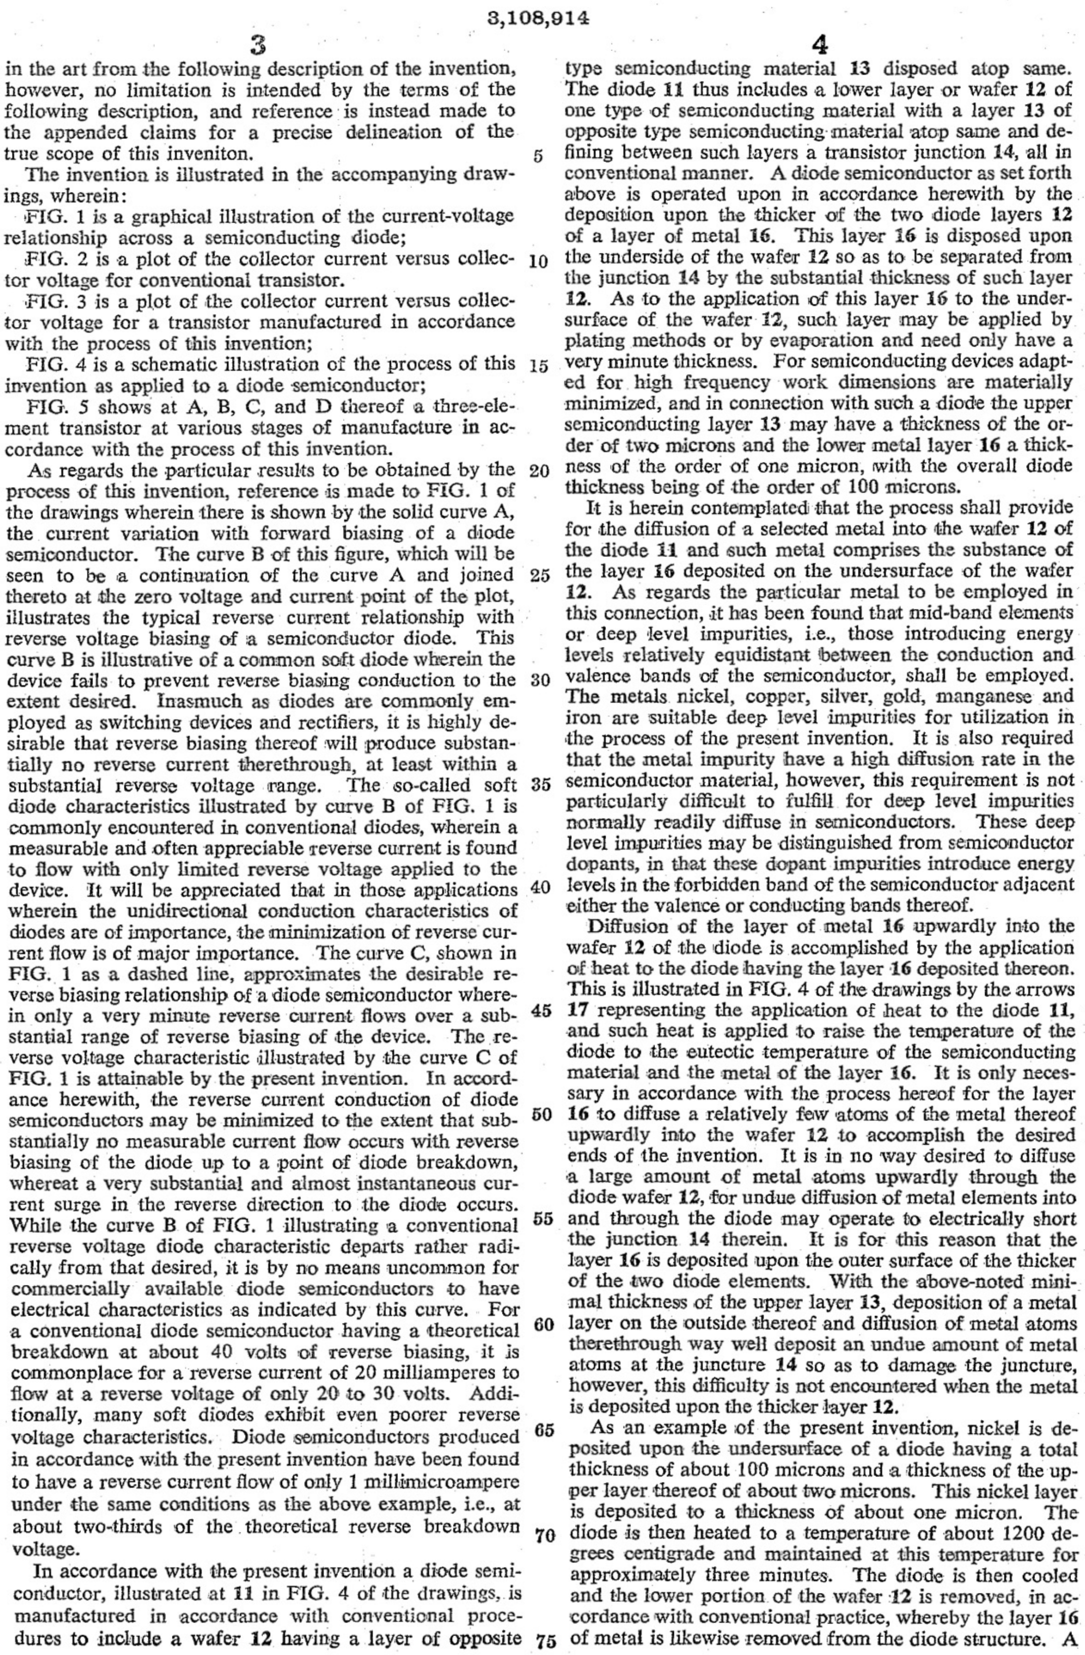
It is another object of the present invention to provide a process for improving the electrical characteristics of semiconducting devices.

It is a further object of the present invention to provide a process for improving the electrical characteristics of transistors to sharpen the current-voltage relationship.

It is yet another object of the present invention to provide an improvement process for establishing sharp characteristics of otherwise soft semiconductor diodes.

Various other objects and possible advantages of the present invention will become apparent to those skilled

Figure B.179: Jean Hoerni invented methods of manufacturing silicon transistors.



in the art from the following description of the invention, however, no limitation is intended by the terms of the following description, and reference is instead made to the appended claims for a precise delineation of the true scope of this inveniton.

The invention is illustrated in the accompanying drawings, wherein:

FIG. 1 is a graphical illustration of the current-voltage relationship across a semiconducting diode;

FIG. 2 is a plot of the collector current versus collector voltage for conventional transistor.

FIG. 3 is a plot of the collector current versus collector voltage for a transistor manufactured in accordance with the process of this invention;

FIG. 4 is a schematic illustration of the process of this invention as applied to a diode semiconductor;

FIG. 5 shows at A, B, C, and D thereof a three-element transistor at various stages of manufacture in accordance with the process of this invention.

As regards the particular results to be obtained by the process of this invention, reference is made to FIG. 1 of the drawings wherein there is shown by the solid curve A, the current variation with forward biasing of a diode semiconductor. The curve B of this figure, which will be seen to be a continuation of the curve A and joined thereto at the zero voltage and current point of the plot, illustrates the typical reverse current relationship with reverse voltage biasing of a semiconductor diode. This curve B is illustrative of a common soft diode wherein the device fails to prevent reverse biasing conduction to the extent desired. Inasmuch as diodes are commonly employed as switching devices and rectifiers, it is highly desirable that reverse biasing thereof will produce substantially no reverse current therethrough, at least within a substantial reverse voltage range. The so-called soft diode characteristics illustrated by curve B of FIG. 1 is commonly encountered in conventional diodes, wherein a measurable and often appreciable reverse current is found to flow with only limited reverse voltage applied to the device. It will be appreciated that in those applications wherein the unidirectional conduction characteristics of diodes are of importance, the minimization of reverse current flow is of major importance. The curve C, shown in FIG. 1 as a dashed line, approximates the desirable reverse biasing relationship of a diode semiconductor wherein only a very minute reverse current flows over a substantial range of reverse biasing of the device. The reverse voltage characteristic illustrated by the curve C of FIG. 1 is attainable by the present invention. In accordance herewith, the reverse current conduction of diode semiconductors may be minimized to the extent that substantially no measurable current flow occurs with reverse biasing of the diode up to a point of diode breakdown, whereat a very substantial and almost instantaneous current surge in the reverse direction to the diode occurs. While the curve B of FIG. 1 illustrating a conventional reverse voltage diode characteristic departs rather radically from that desired, it is by no means uncommon for commercially available diode semiconductors to have electrical characteristics as indicated by this curve. For a conventional diode semiconductor having a theoretical breakdown at about 40 volts of reverse biasing, it is commonplace for a reverse current of 20 milliamperes to flow at a reverse voltage of only 20 to 30 volts. Additionally, many soft diodes exhibit even poorer reverse voltage characteristics. Diode semiconductors produced in accordance with the present invention have been found to have a reverse current flow of only 1 millimicroampere under the same conditions as the above example, i.e., at about two-thirds of the theoretical reverse breakdown voltage.

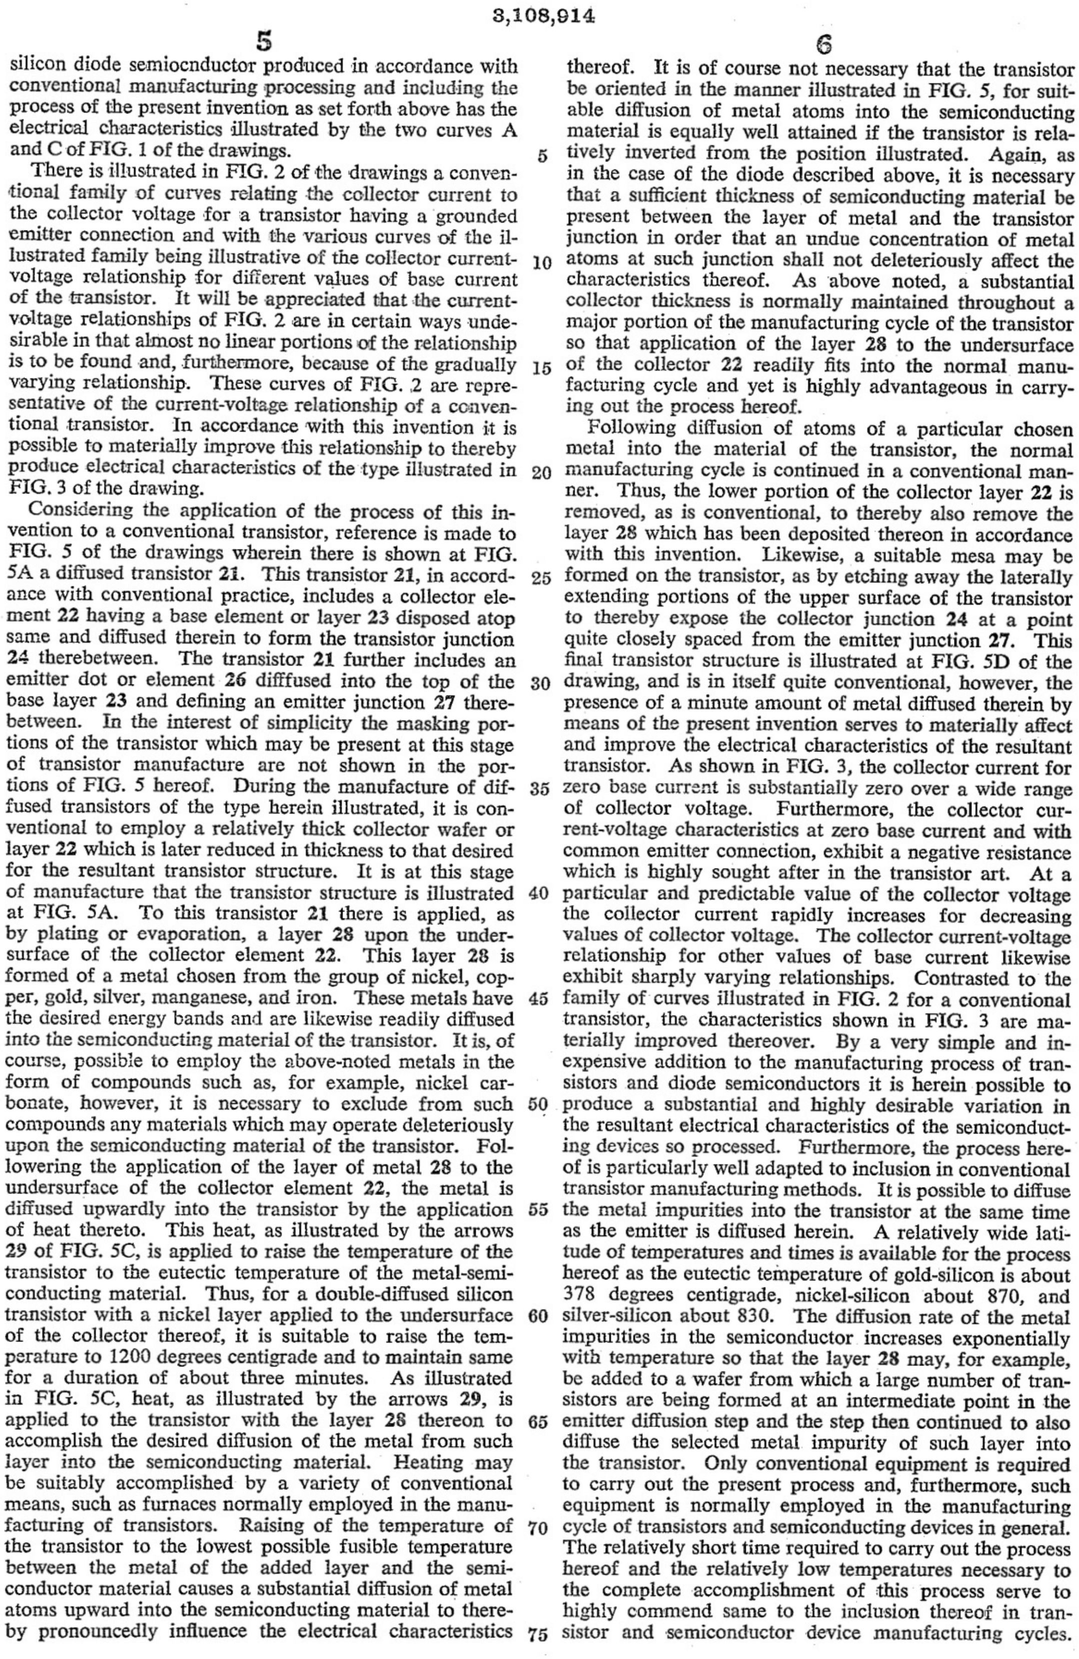
In accordance with the present invention a diode semiconductor, illustrated at **11** in FIG. 4 of the drawings, is manufactured in accordance with conventional procedures to include a wafer **12** having a layer of opposite type semiconducting material **13** disposed atop same. The diode **11** thus includes a lower layer or wafer **12** of one type of semiconducting material with a layer **13** of opposite type semiconducting material atop same and defining between such layers a transistor junction **14**, all in conventional manner. A diode semiconductor as set forth above is operated upon in accordance herewith by the deposition upon the thicker of the two diode layers **12** of a layer of metal **16**. This layer **16** is disposed upon the underside of the wafer **12** so as to be separated from the junction **14** by the substantial thickness of such layer **12**. As to the application of this layer **16** to the undersurface of the wafer **12**, such layer may be applied by plating methods or by evaporation and need only have a very minute thickness. For semiconducting devices adapted for high frequency work dimensions are materially minimized, and in connection with such a diode the upper semiconducting layer **13** may have a thickness of the order of two microns and the lower metal layer **16** a thickness of the order of one micron, with the overall diode thickness being of the order of 100 microns.

It is herein contemplated that the process shall provide for the diffusion of a selected metal into the wafer **12** of the diode **11** and such metal comprises the substance of the layer **16** deposited on the undersurface of the wafer **12**. As regards the particular metal to be employed in this connection, it has been found that mid-band elements or deep level impurities, i.e., those introducing energy levels relatively equidistant between the conduction and valence bands of the semiconductor, shall be employed. The metals nickel, copper, silver, gold, manganese and iron are suitable deep level impurities for utilization in the process of the present invention. It is also required that the metal impurity have a high diffusion rate in the semiconductor material, however, this requirement is not particularly difficult to fulfill for deep level impurities normally readily diffuse in semiconductors. These deep level impurities may be distinguished from semiconductor dopants, in that these dopant impurities introduce energy levels in the forbidden band of the semiconductor adjacent either the valence or conducting bands thereof.

Diffusion of the layer of metal **16** upwardly into the wafer **12** of the diode is accomplished by the application of heat to the diode having the layer **16** deposited thereon. This is illustrated in FIG. 4 of the drawings by the arrows **17** representing the application of heat to the diode **11**, and such heat is applied to raise the temperature of the diode to the eutectic temperature of the semiconducting material and the metal of the layer **16**. It is only necessary in accordance with the process hereof for the layer **16** to diffuse a relatively few atoms of the metal thereof upwardly into the wafer **12** to accomplish the desired ends of the invention. It is in no way desired to diffuse a large amount of metal atoms upwardly through the diode wafer **12**, for undue diffusion of metal elements into and through the diode may operate to electrically short the junction **14** therein. It is for this reason that the layer **16** is deposited upon the outer surface of the thicker of the two diode elements. With the above-noted minimal thickness of the upper layer **13**, deposition of a metal layer on the outside thereof and diffusion of metal atoms therethrough way well deposit an undue amount of metal atoms at the juncture **14** so as to damage the juncture, however, this difficulty is not encountered when the metal is deposited upon the thicker layer **12**.

As an example of the present invention, nickel is deposited upon the undersurface of a diode having a total thickness of about 100 microns and a thickness of the upper layer thereof of about two microns. This nickel layer is deposited to a thickness of about one micron. The diode is then heated to a temperature of about 1200 degrees centigrade and maintained at this temperature for approximately three minutes. The diode is then cooled and the lower portion of the wafer **12** is removed, in accordance with conventional practice, whereby the layer **16** of metal is likewise removed from the diode structure. A

Figure B.180: Jean Hoerni invented methods of manufacturing silicon transistors.



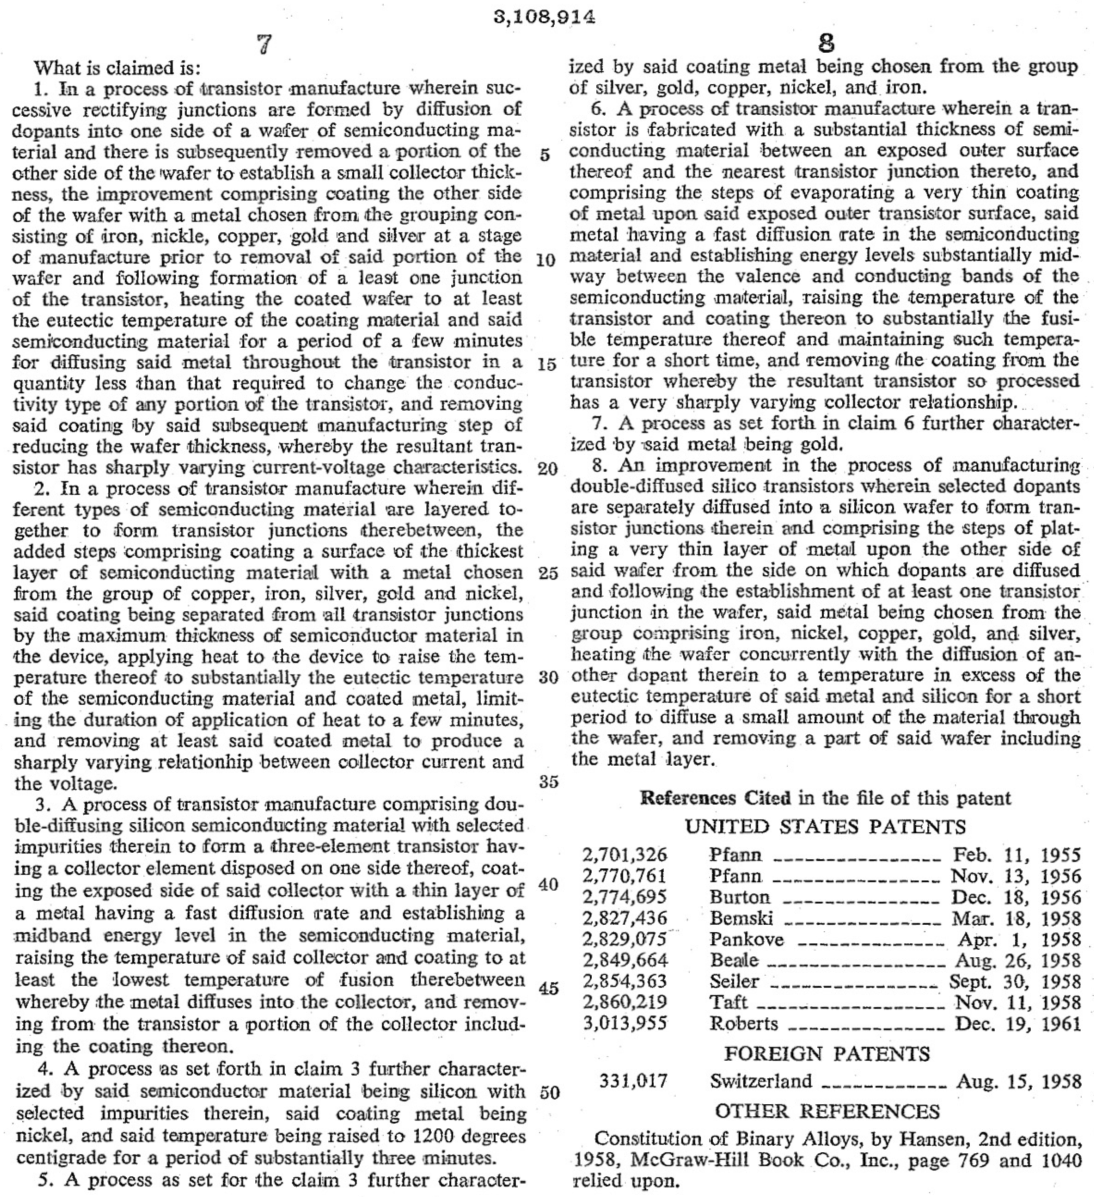
silicon diode semiocnductor produced in accordance with conventional manufacturing processing and including the process of the present invention as set forth above has the electrical characteristics illustrated by the two curves A and C of FIG. 1 of the drawings.

There is illustrated in FIG. 2 of the drawings a conventional family of curves relating the collector current to the collector voltage for a transistor having a grounded emitter connection and with the various curves of the illustrated family being illustrative of the collector current-voltage relationship for different values of base current of the transistor. It will be appreciated that the current-voltage relationships of FIG. 2 are in certain ways undesirable in that almost no linear portions of the relationship is to be found and, furthermore, because of the gradually varying relationship. These curves of FIG. 2 are representative of the current-voltage relationship of a conventional transistor. In accordance with this invention it is possible to materially improve this relationship to thereby produce electrical characteristics of the type illustrated in FIG. 3 of the drawing.

Considering the application of the process of this invention to a conventional transistor, reference is made to FIG. 5 of the drawings wherein there is shown at FIG. 5A a diffused transistor **21**. This transistor **21**, in accordance with conventional practice, includes a collector element **22** having a base element or layer **23** disposed atop same and diffused therein to form the transistor junction **24** therebetween. The transistor **21** further includes an emitter dot or element **26** difffused into the top of the base layer **23** and defining an emitter junction **27** therebetween. In the interest of simplicity the masking portions of the transistor which may be present at this stage of transistor manufacture are not shown in the portions of FIG. 5 hereof. During the manufacture of diffused transistors of the type herein illustrated, it is conventional to employ a relatively thick collector wafer or layer **22** which is later reduced in thickness to that desired for the resultant transistor structure. It is at this stage of manufacture that the transistor structure is illustrated at FIG. 5A. To this transistor **21** there is applied, as by plating or evaporation, a layer **28** upon the undersurface of the collector element **22**. This layer **28** is formed of a metal chosen from the group of nickel, copper, gold, silver, manganese, and iron. These metals have the desired energy bands and are likewise readily diffused into the semiconducting material of the transistor. It is, of course, possible to employ the above-noted metals in the form of compounds such as, for example, nickel carbonate, however, it is necessary to exclude from such compounds any materials which may operate deleteriously upon the semiconducting material of the transistor. Followering the application of the layer of metal **28** to the undersurface of the collector element **22**, the metal is diffused upwardly into the transistor by the application of heat thereto. This heat, as illustrated by the arrows **29** of FIG. 5C, is applied to raise the temperature of the transistor to the eutectic temperature of the metal-semiconducting material. Thus, for a double-diffused silicon transistor with a nickel layer applied to the undersurface of the collector thereof, it is suitable to raise the temperature to 1200 degrees centigrade and to maintain same for a duration of about three minutes. As illustrated in FIG. 5C, heat, as illustrated by the arrows **29**, is applied to the transistor with the layer **28** thereon to accomplish the desired diffusion of the metal from such layer into the semiconducting material. Heating may be suitably accomplished by a variety of conventional means, such as furnaces normally employed in the manufacturing of transistors. Raising of the temperature of the transistor to the lowest possible fusible temperature between the metal of the added layer and the semiconductor material causes a substantial diffusion of metal atoms upward into the semiconducting material to thereby pronouncedly influence the electrical characteristics thereof. It is of course not necessary that the transistor be oriented in the manner illustrated in FIG. 5, for suitable diffusion of metal atoms into the semiconducting material is equally well attained if the transistor is relatively inverted from the position illustrated. Again, as in the case of the diode described above, it is necessary that a sufficient thickness of semiconducting material be present between the layer of metal and the transistor junction in order that an undue concentration of metal atoms at such junction shall not deleteriously affect the characteristics thereof. As above noted, a substantial collector thickness is normally maintained throughout a major portion of the manufacturing cycle of the transistor so that application of the layer **28** to the undersurface of the collector **22** readily fits into the normal manufacturing cycle and yet is highly advantageous in carrying out the process hereof.

Following diffusion of atoms of a particular chosen metal into the material of the transistor, the normal manufacturing cycle is continued in a conventional manner. Thus, the lower portion of the collector layer **22** is removed, as is conventional, to thereby also remove the layer **28** which has been deposited thereon in accordance with this invention. Likewise, a suitable mesa may be formed on the transistor, as by etching away the laterally extending portions of the upper surface of the transistor to thereby expose the collector junction **24** at a point quite closely spaced from the emitter junction **27**. This final transistor structure is illustrated at FIG. 5D of the drawing, and is in itself quite conventional, however, the presence of a minute amount of metal diffused therein by means of the present invention serves to materially affect and improve the electrical characteristics of the resultant transistor. As shown in FIG. 3, the collector current for zero base current is substantially zero over a wide range of collector voltage. Furthermore, the collector current-voltage characteristics at zero base current and with common emitter connection, exhibit a negative resistance which is highly sought after in the transistor art. At a particular and predictable value of the collector voltage the collector current rapidly increases for decreasing values of collector voltage. The collector current-voltage relationship for other values of base current likewise exhibit sharply varying relationships. Contrasted to the family of curves illustrated in FIG. 2 for a conventional transistor, the characteristics shown in FIG. 3 are materially improved thereover. By a very simple and inexpensive addition to the manufacturing process of transistors and diode semiconductors it is herein possible to produce a substantial and highly desirable variation in the resultant electrical characteristics of the semiconducting devices so processed. Furthermore, the process hereof is particularly well adapted to inclusion in conventional transistor manufacturing methods. It is possible to diffuse the metal impurities into the transistor at the same time as the emitter is diffused herein. A relatively wide latitude of temperatures and times is available for the process hereof as the eutectic temperature of gold-silicon is about 378 degrees centigrade, nickel-silicon about 870, and silver-silicon about 830. The diffusion rate of the metal impurities in the semiconductor increases exponentially with temperature so that the layer **28** may, for example, be added to a wafer from which a large number of transistors are being formed at an intermediate point in the emitter diffusion step and the step then continued to also diffuse the selected metal impurity of such layer into the transistor. Only conventional equipment is required to carry out the present process and, furthermore, such equipment is normally employed in the manufacturing cycle of transistors and semiconducting devices in general. The relatively short time required to carry out the process hereof and the relatively low temperatures necessary to the complete accomplishment of this process serve to highly commend same to the inclusion thereof in transistor and semiconductor device manufacturing cycles.

Figure B.181: Jean Hoerni invented methods of manufacturing silicon transistors.



3,108,914

7

What is claimed is:

1. In a process of transistor manufacture wherein successive rectifying junctions are formed by diffusion of dopants into one side of a wafer of semiconducting material and there is subsequently removed a portion of the other side of the wafer to establish a small collector thickness, the improvement comprising coating the other side of the wafer with a metal chosen from the grouping consisting of iron, nickle, copper, gold and silver at a stage of manufacture prior to removal of said portion of the wafer and following formation of a least one junction of the transistor, heating the coated wafer to at least the eutectic temperature of the coating material and said semiconducting material for a period of a few minutes for diffusing said metal throughout the transistor in a quantity less than that required to change the conductivity type of any portion of the transistor, and removing said coating by said subsequent manufacturing step of reducing the wafer thickness, whereby the resultant transistor has sharply varying current-voltage characteristics.

2. In a process of transistor manufacture wherein different types of semiconducting material are layered together to form transistor junctions therebetween, the added steps comprising coating a surface of the thickest layer of semiconducting material with a metal chosen from the group of copper, iron, silver, gold and nickel, said coating being separated from all transistor junctions by the maximum thickness of semiconductor material in the device, applying heat to the device to raise the temperature thereof to substantially the eutectic temperature of the semiconducting material and coated metal, limiting the duration of application of heat to a few minutes, and removing at least said coated metal to produce a sharply varying relationhip between collector current and the voltage.

3. A process of transistor manufacture comprising double-diffusing silicon semiconducting material with selected impurities therein to form a three-element transistor having a collector element disposed on one side thereof, coating the exposed side of said collector with a thin layer of a metal having a fast diffusion rate and establishing a midband energy level in the semiconducting material, raising the temperature of said collector and coating to at least the lowest temperature of fusion therebetween whereby the metal diffuses into the collector, and removing from the transistor a portion of the collector including the coating thereon.

4. A process as set forth in claim 3 further characterized by said semiconductor material being silicon with selected impurities therein, said coating metal being nickel, and said temperature being raised to 1200 degrees centigrade for a period of substantially three minutes.

5. A process as set for the claim 3 further characterized by said coating metal being chosen from the group of silver, gold, copper, nickel, and iron.

8

6. A process of transistor manufacture wherein a transistor is fabricated with a substantial thickness of semiconducting material between an exposed outer surface thereof and the nearest transistor junction thereto, and comprising the steps of evaporating a very thin coating of metal upon said exposed outer transistor surface, said metal having a fast diffusion rate in the semiconducting material and establishing energy levels substantially midway between the valence and conducting bands of the semiconducting material, raising the temperature of the transistor and coating thereon to substantially the fusible temperature thereof and maintaining such temperature for a short time, and removing the coating from the transistor whereby the resultant transistor so processed has a very sharply varying collector relationship.

7. A process as set forth in claim 6 further characterized by said metal being gold.

8. An improvement in the process of manufacturing double-diffused silico transistors wherein selected dopants are separately diffused into a silicon wafer to form transistor junctions therein and comprising the steps of plating a very thin layer of metal upon the other side of said wafer from the side on which dopants are diffused and following the establishment of at least one transistor junction in the wafer, said metal being chosen from the group comprising iron, nickel, copper, gold, and silver, heating the wafer concurrently with the diffusion of another dopant therein to a temperature in excess of the eutectic temperature of said metal and silicon for a short period to diffuse a small amount of the material through the wafer, and removing a part of said wafer including the metal layer.

10 Claims. (Cl. 29—571)

ABSTRACT OF THE DISCLOSURE

The conductivity of that portion of the channel of an offset insulated gate field effect transistor which is not covered by the gate electrode is increased by heating the transistor in a hydrogen-containing ambient after the formation of the gate electrode.

This invention relates to improved methods of fabricating semiconductive devices, and more particularly to improved methods of introducing or forming a conductive channel in semiconductive devices.

In the fabrication of certain types of semiconductor devices, e.g., those known as MOS transistors, a thin conductive channel or region is formed in a crystalline semiconductive wafer. Conductive channels have been formed in semiconductive wafers by alloying a quantity of a conductivity type-determining substances or modifier (a substance which is either an acceptor or a donor in the particular semiconductor employed) to the surface of the wafer. Conductive channels have also been formed in a semiconductive wafer by diffusing a conductivity modifier through all or part of the wafer surface. Another method of forming a conductive channel is to deposit heavily doped low resistivity semiconductive material as a thin epitaxial layer on a high resistivity wafer of the same semiconductive material.

It is known that when some crystalline semiconductive bodies are heated to high temperatures, a thin surface layer of the body is often converted to opposite conductivity type. For example, when a P type silicon wafer is heated in steam or in ordinary oxidizing ambients such as air or oxygen to form a silicon oxide surface layer on the surface of the wafer, a thin surface region of the wafer immediately beneath the silicon oxide layer tends to become N type. However, the N type surface region thus produced is not presently preferred for use as a conductive channel in the kind of semiconductor device known as an insulated gate field-effect device, because the surface states of crystalline silicon wafers are very sensitive to surface preparation, oxidation processes, and the past history of the silicon crystal, so that results obtained depend on the specific treatments utilized during fabrication. It is believed that the ordinary N type inversion layer formed by oxidizing a silicon body in steam or in other conventional ambient has a great many associated surface states which act as traps, and tend to immobilize charge carriers, thus decreasing the transconductance of the device to undesirable levels.

In the fabrication of some kinds of semiconductor devices, such as insulated gate field-effect devices. it is desirable that the conductive channels in a large number of units be closely similar as to size, shape, and resistivity, in order to insure uniforimty in the electrical parameters of the completed device. For some types of these devices, it is also desirable that the conductive channel be non-uniform in its electrical resistivity from one end of the channel to the other end, although the conductive channel should nevertheless be similar from device to device.

It is an object of this invention to provide improved methods of fabricating improved semiconductor devices. It is another object of the invention to reduce the time

2

and cost of fabricating thin conductive channels in semiconductive devices.

Still another object is to provide improved methods of forming, in crystalline semiconductive wafers, conductive channels that are uniform from wafer to wafer.

But aonther object is to provide a rapid and inexpensive method of forming in a semiconductive wafer a thin conductive channel which is non-uniform in conductivity from one end of the channel to the other end.

The present method of forming a conductive channel in a crystalline semiconductive body comprises the steps of forming an insulating coating over one face of said body; depositing a metallic electrode over a portion of said coating, leaving the remaining portion of said coating uncovered by said electrode; and treating said body in an ambient capable of increasing the conductivity of that portion of said one face uncovered by said electrode.

The invention and its features will be described in greater detail with reference to the accompanying drawing, in which:

FIGURE 1 is a perspective view of a semiconductive wafer;

FIGURES 2–12 are cross-sectional views of a portion of the semiconductive wafer of FIGURE 1 during successive steps in the fabrication of a semiconductor device in accordance with one embodiment of the present method;

FIGURE 13 is a plot of the electrical characteristics of a prior art device which is comparable to the device illustrated in FIGURE 12; and

FIGURE 14 is a plot of the electrical characteristics of the device of FIGURE 12, showing the characteristic variation in the source-drain current with source-drain voltage for different values of source-gate bias.

The type of semiconductor device in which the conductivity of a portion of a semiconductive wafer may be modulated by an applied electric field is known as a field-effect device. One kind of field-effect device comprises a semiconductive wafer which has an insulating layer over a portion of one surface thereof, and has a control electrode disposed on this insulating layer and spaced thereby from the surface of the wafer. Units of this kind are known as insulated gate field-effect devices, and generally comprise a layer or wafer of crystalline semiconductive material; two spaced conductive regions adjacent one face of said semiconductive material; a film of insulating material on said one face between said two spaced regions; two conductive metallic electrodes bonded to said two spaced conductive regions respectily; and a conductive metallic electrode on said insulating film over the gap or space between said two spaced regions.

One class of insulated gate device is known as the MOS (Metal-Oxide Semiconductor) transistor, and is described by S. R. Hofstein and F. P. Heiman in "The Silicon Insulated-Gate Field-Effect Transistor," Proc. IEEE, volume 51, p. 1190, September 1963. In devices of this type, the metallic control electrode on the insulating film (the film may for example consist of silicon oxide) is also known as the gate electrode, while the two electrodes bonded directly to the semiconductive wafer are known as the source and drain electrodes.

MOS transistors may be of two general types, one type being known as the enhancement type, and the other as the depletion type. In depletion type MOS transistors, there is a thin conductive channel adjacent the wafer surface between the source and drain regions. In devices of this type, a drain current will flow even when the gate bias is zero. When a negative gate bias is applied to depletion type MOS transistors having an N type conductive channel, the conductivity of the conductive channel is decreased or "pinched off" and the source-drain

Figure B.186: Karl Heinz Zaininger invented methods of manufacturing field effect transistors.

current is decreased. When a positive gate bias is applied to these devices, the conductivity of the channel increases, and the source-drain current increases. In depletion type MOS transistors having a P type conductive channel, the applied gate bias must be reversed in polarity to produce the same effect. Thus both positive and negative gate biases are effective in modulating the drain current of depletion type MOS transistors.

In one class of MOS transistors known as offset gate units, the control or gate electrode lies over only a portion of the conductive channel between the source and drain regions of the device. For a description of this type of device, see F. P. Heiman and S. R. Hofstein, "Metal-Oxide-Semiconductor Field-Effect Transistors," Electronics, Nov. 30, 1964, pp. 50–61.

Although the present method will be described in terms of an offset gate depletion type MOS transistor as a specific example, the method may also be applied to the fabrication of other types of semiconductor devices in which it is desired to fabricate a conductive channel in a crystalline semiconductive wafer beneath an insulating layer.

Example I

A crystalline silicon wafer **10** (FIGURE 1) is prepared with two opposing major faces **11** and **12**. The precise size, shape, conductivity type and resistivity of the wafer **10** is not critical. The wafer **10** may be of P type conductivity, or intrinsic, or of N type conductivity. In this example, the wafer **10** is a disc-shaped transverse slice of a monocrystalline P type ingot, and has a resistivity of about 1 to 100 ohm-cm. Suitably, the wafer **10** is about ¾ of an inch in diameter and 6 mils thick. It will be understood that a large number of units are simultaneously fabricated from a wafer of this size. In FIGURES 2–12, only a small portion of the entire semiconductive wafer **10**, and only small portions of the two opposing major faces **11** and **12**, are shown for greater clarity.

A silicon oxide coating is deposited over the surface of the wafer **10** by any convenient method. Since this coating is subsequently removed, its exact thickness is not critical. When the wafer **10** consists of silicon, as in this example, the silicon oxide layer may be formed by heating the wafer in steam for about 30 minutes at about 1050° C. Silicon oxide coatings **14** and **15** (FIGURE 2) are thus grown on major faces **11** and **12** respectively of the wafer. A thin layer **16** of a photoresist is deposited on one oxide coating **14**. The photoresist **16** may, for example, be a bichromated protein such as bichromated gum arabic, or may be a commercially available photoresist.

The photoresist layer **16** is exposed to a suitable light pattern, and developed. Those portions of the photoresist not exposed to light are removed by means of a suitable solvent, thereby exposing portions of silicon oxide layer **14**. The hardened, polymerized portions of the photoresist which remain on silicon oxide layer **14** serve as a mask during the subsequent etching step. The exposed portions of the silicon oxide layer **14** are removed by means of an etchant such as a hydrofluoric acid solution. The polymerized portions of the photoresist are then removed by means of a suitable stripper such as methylene chloride, leaving wafer **10** as in FIGURE 3, with a pair of openings **17** and **18** formed in the silicon oxide layer **14** on the wafer **10**.

The exact size and shape of openings **17** and **18** are not critical; they may be regular shapes such as polygons or circles, or may be irregular in shape. When the source and drain regions of an MOS transistor have the same size and shape, the device is symmetrical, that is, source and drain regions may be interchanged without affecting electrical characteristics of the device. In this example, the openings **17** and **18** are rectangular, but the area of one opening **18** is made very small, for example, about 30 square mils, and is smaller than the area of the other opening **17**. It has been found that improved operation at elevated frequencies is obtained by making the drain area of an MOS transistor very small. The area of the source region does not appreciably affect the high frequency performance of the device, and hence may be made relatively large for greater ease in bonding lead wires.

Wafer **10** is next heated in an ambient containing phosphorus pentoxide vapors for about 10 to 20 minutes at about 1000° C. Phosphorus diffuses into the exposed portions of wafer face **11** to form two phosphorus diffused regions **19** and **21** (FIGURE 4) immediately beneath openings **17** and **18** respectively. Since phosphorus is a donor in silicon, and the wafer **10** is originally of P type conductivity, rectifying barriers or p-n junctions **20** and **22** are formed at the boundaries between the N type phosphorus-diffused regions **19** and **21** respectively and the P type bulk of wafer **10**. Under these conditions, the N type phosphorus-diffused regions **19** and **21** may be about 5000 to 20,000 Angstroms thick, depending on the period of heating and the concentration of the phosphorus pentoxide vapors. In this example, the exposed surface area of region **21** is less than the exposed surface area of region **19**, as the area of opening **18** was less than the area of opening **17**.

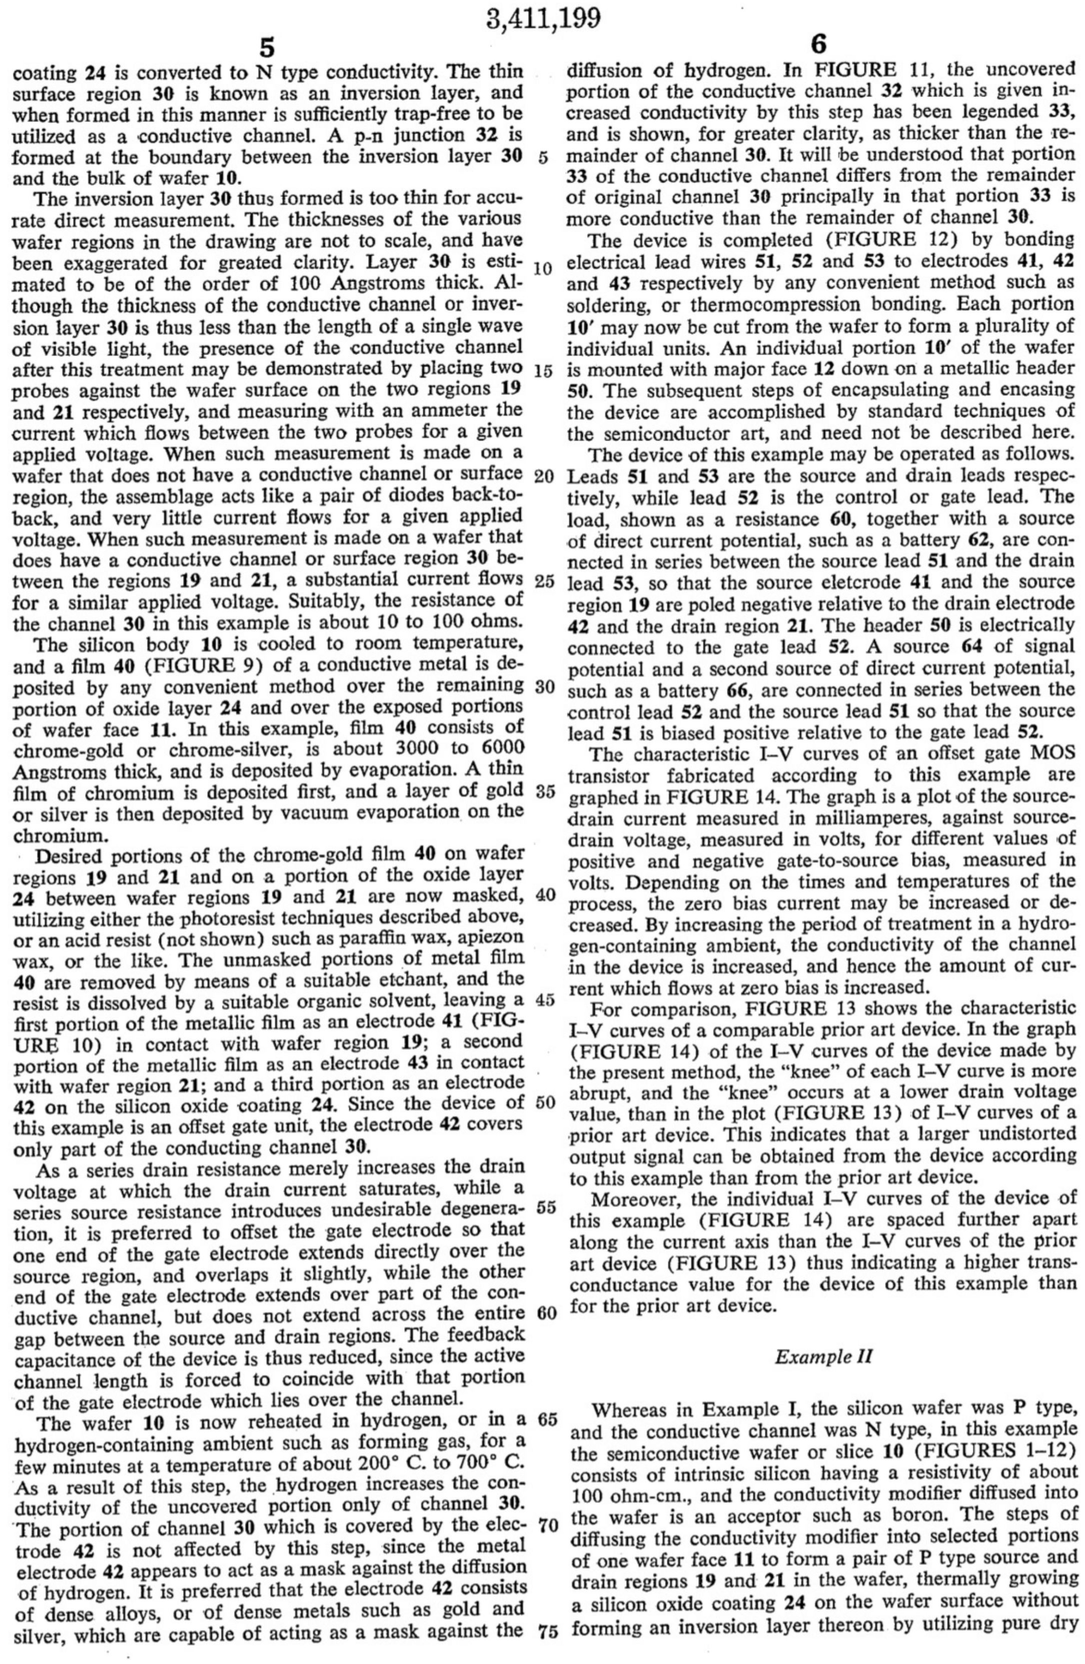
Wafer **10** is now treated in an etchant containing hydrofluoric acid so as to completely remove the oxide layer **15** and the remaining portions of the oxide layer **14**, leaving the wafer as in FIGURE 5.

Wafer **10** is reheated in an ambient of pure dry oxygen for a time and at a temperature sufficient to form a silicon oxide coating or layer thereon. The exact time and temperature of this heating step is not critical. At higher temperatures, a shorter heating time may be utilized. At low temperatures, a longer heating time is required to produce the same coating thickness. In this example, wafer **10** is heated at about 1000° C. for about 3 to 4 hours. Clean new silicon oxide coatings **24** and **25** (FIGURE 6) about 1000 to 3000 Angstroms thick are thus formed on wafer faces **11** and **12** respectively. It has been found that when oxide coatings are formed on silicon wafers in this manner, in the absence of moisture or impurities, the tendency for silicon wafers to develop surface inversion layers is minimized.

A thin layer **26** (FIGURE 6) of photoresist is deposited on silicon oxide coating **24**. The photoresist layer **26** is exposed to a suitable light pattern. Unexposed portions of the photoresist are then removed by any suitable solvent, thereby exposing portions of silicon oxide layer **24**. The exposed portions of silicon oxide layer **24**, as well as all of silicon oxide layer **25**, are then removed by means of a hydrofluoric acid solution. The remaining portions of the photoresist are then removed with a suitable stripper, leaving the wafer as in FIGURE 7, with contact openings **27** and **28** extending through the oxide coating **24** to the face **11** of wafer **10**. The exact size and shape of contact openings **27** and **28** is not critical, but openings **27** and **28** are entirely within the surface boundary of the phosphorus-diffused N type regions **19** and **21** respectively.

Wafer **10** is now heated in a reducing ambient such as hydrogen or a mixture of hydrogen and a non-oxidizing gas such as argon, nitrogen, or the like. Mixtures of nitrogen and a few volume percent hydrogen are useful for this purpose, and are known as forming gas. A suitable forming gas consists of 90 volumes of nitrogen and 10 volumes of hydrogen. The heating step is preferably conducted at temperatures of about 200° C. to 700° C. At about 700° C., heating for less than a minute is sufficient. If the heating temperature is decreased, the time of heating is increased. During this step, a thin surface region **30** (FIGURE 8) of wafer **10** beneath the silicon oxide

Figure B.187: Karl Heinz Zaininger invented methods of manufacturing field effect transistors.



coating **24** is converted to N type conductivity. The thin surface region **30** is known as an inversion layer, and when formed in this manner is sufficiently trap-free to be utilized as a conductive channel. A p-n junction **32** is formed at the boundary between the inversion layer **30** and the bulk of wafer **10**.

The inversion layer **30** thus formed is too thin for accurate direct measurement. The thicknesses of the various wafer regions in the drawing are not to scale, and have been exaggerated for greated clarity. Layer **30** is estimated to be of the order of 100 Angstroms thick. Although the thickness of the conductive channel or inversion layer **30** is thus less than the length of a single wave of visible light, the presence of the conductive channel after this treatment may be demonstrated by placing two probes against the wafer surface on the two regions **19** and **21** respectively, and measuring with an ammeter the current which flows between the two probes for a given applied voltage. When such measurement is made on a wafer that does not have a conductive channel or surface region, the assemblage acts like a pair of diodes back-to-back, and very little current flows for a given applied voltage. When such measurement is made on a wafer that does have a conductive channel or surface region **30** between the regions **19** and **21**, a substantial current flows for a similar applied voltage. Suitably, the resistance of the channel **30** in this example is about 10 to 100 ohms.

The silicon body **10** is cooled to room temperature, and a film **40** (FIGURE 9) of a conductive metal is deposited by any convenient method over the remaining portion of oxide layer **24** and over the exposed portions of wafer face **11**. In this example, film **40** consists of chrome-gold or chrome-silver, is about 3000 to 6000 Angstroms thick, and is deposited by evaporation. A thin film of chromium is deposited first, and a layer of gold or silver is then deposited by vacuum evaporation on the chromium.

Desired portions of the chrome-gold film **40** on wafer regions **19** and **21** and on a portion of the oxide layer **24** between wafer regions **19** and **21** are now masked, utilizing either the photoresist techniques described above, or an acid resist (not shown) such as paraffin wax, apiezon wax, or the like. The unmasked portions of metal film **40** are removed by means of a suitable etchant, and the resist is dissolved by a suitable organic solvent, leaving a first portion of the metallic film as an electrode **41** (FIGURE 10) in contact with wafer region **19**; a second portion of the metallic film as an electrode **43** in contact with wafer region **21**; and a third portion as an electrode **42** on the silicon oxide coating **24**. Since the device of this example is an offset gate unit, the electrode **42** covers only part of the conducting channel **30**.

As a series drain resistance merely increases the drain voltage at which the drain current saturates, while a series source resistance introduces undesirable degeneration, it is preferred to offset the gate electrode so that one end of the gate electrode extends directly over the source region, and overlaps it slightly, while the other end of the gate electrode extends over part of the conductive channel, but does not extend across the entire gap between the source and drain regions. The feedback capacitance of the device is thus reduced, since the active channel length is forced to coincide with that portion of the gate electrode which lies over the channel.

The wafer **10** is now reheated in hydrogen, or in a hydrogen-containing ambient such as forming gas, for a few minutes at a temperature of about 200° C. to 700° C. As a result of this step, the hydrogen increases the conductivity of the uncovered portion only of channel **30**. The portion of channel **30** which is covered by the electrode **42** is not affected by this step, since the metal electrode **42** appears to act as a mask against the diffusion of hydrogen. It is preferred that the electrode **42** consists of dense alloys, or of dense metals such as gold and silver, which are capable of acting as a mask against the diffusion of hydrogen. In FIGURE 11, the uncovered portion of the conductive channel **32** which is given increased conductivity by this step has been legended **33**, and is shown, for greater clarity, as thicker than the remainder of channel **30**. It will be understood that portion **33** of the conductive channel differs from the remainder of original channel **30** principally in that portion **33** is more conductive than the remainder of channel **30**.

The device is completed (FIGURE 12) by bonding electrical lead wires **51**, **52** and **53** to electrodes **41**, **42** and **43** respectively by any convenient method such as soldering, or thermocompression bonding. Each portion **10′** may now be cut from the wafer to form a plurality of individual units. An individual portion **10′** of the wafer is mounted with major face **12** down on a metallic header **50**. The subsequent steps of encapsulating and encasing the device are accomplished by standard techniques of the semiconductor art, and need not be described here.

The device of this example may be operated as follows. Leads **51** and **53** are the source and drain leads respectively, while lead **52** is the control or gate lead. The load, shown as a resistance **60**, together with a source of direct current potential, such as a battery **62**, are connected in series between the source lead **51** and the drain lead **53**, so that the source eletcrode **41** and the source region **19** are poled negative relative to the drain electrode **42** and the drain region **21**. The header **50** is electrically connected to the gate lead **52**. A source **64** of signal potential and a second source of direct current potential, such as a battery **66**, are connected in series between the control lead **52** and the source lead **51** so that the source lead **51** is biased positive relative to the gate lead **52**.

The characteristic I–V curves of an offset gate MOS transistor fabricated according to this example are graphed in FIGURE 14. The graph is a plot of the source-drain current measured in milliamperes, against source-drain voltage, measured in volts, for different values of positive and negative gate-to-source bias, measured in volts. Depending on the times and temperatures of the process, the zero bias current may be increased or decreased. By increasing the period of treatment in a hydrogen-containing ambient, the conductivity of the channel in the device is increased, and hence the amount of current which flows at zero bias is increased.

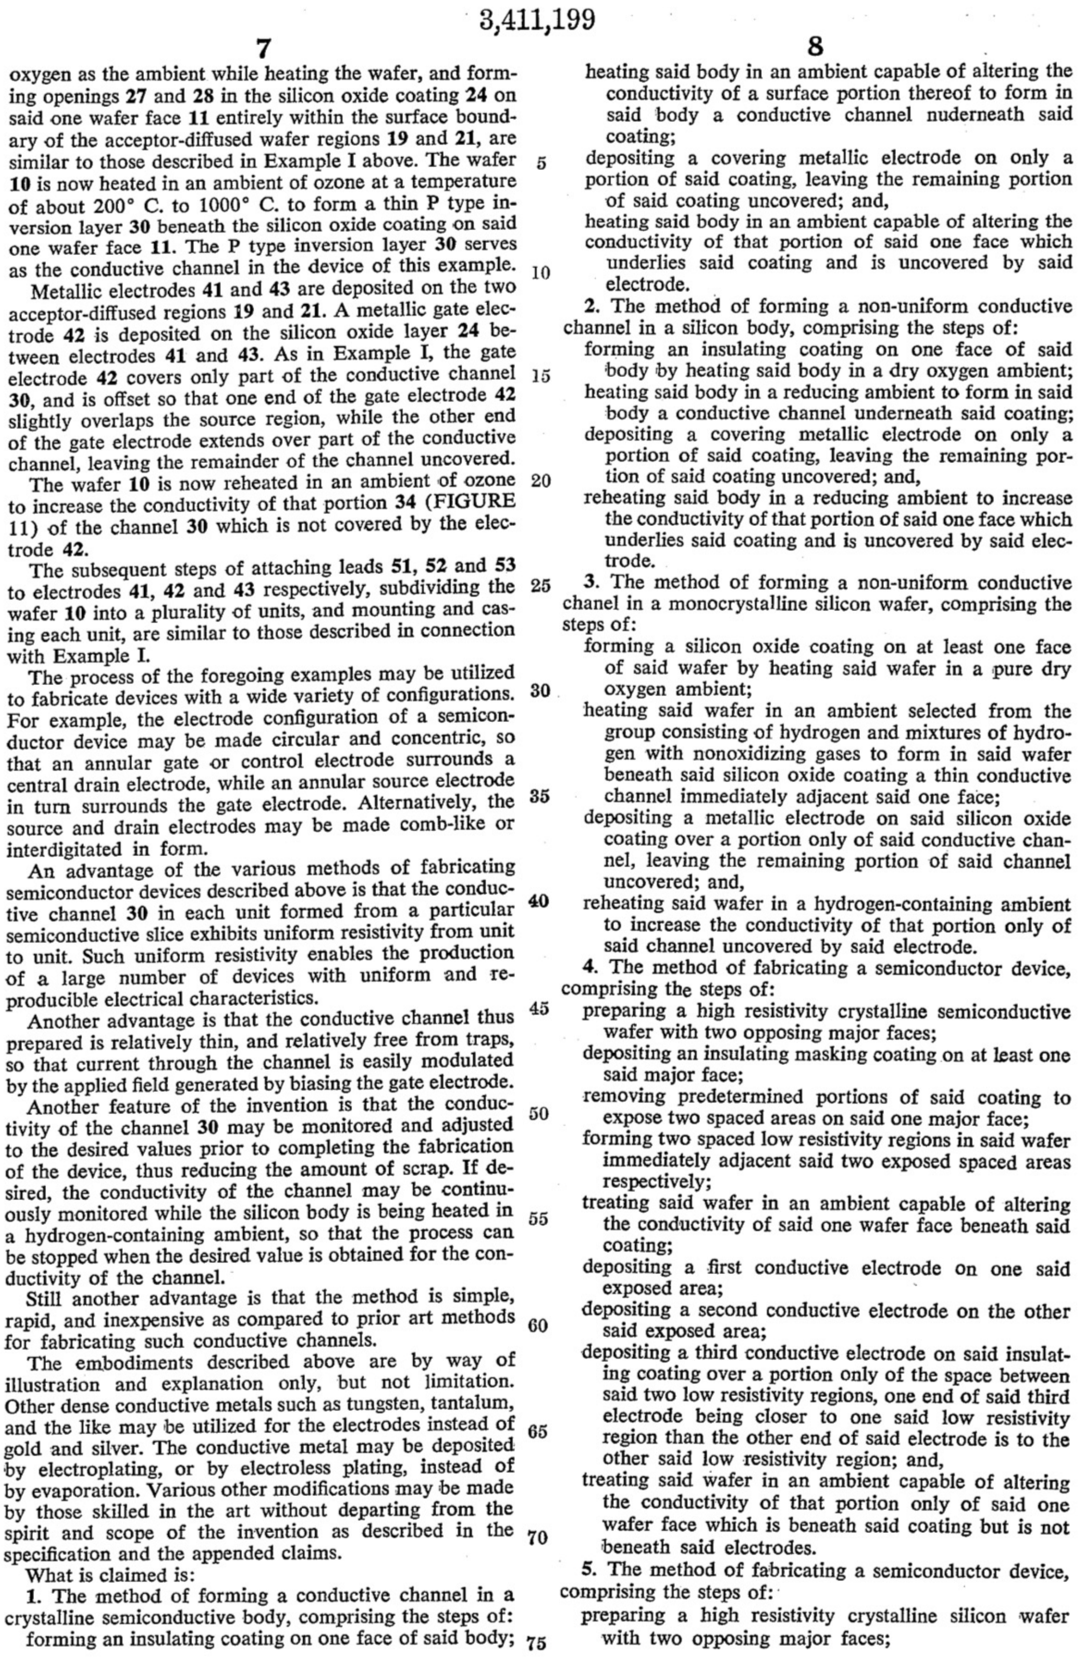
For comparison, FIGURE 13 shows the characteristic I–V curves of a comparable prior art device. In the graph (FIGURE 14) of the I–V curves of the device made by the present method, the "knee" of each I–V curve is more abrupt, and the "knee" occurs at a lower drain voltage value, than in the plot (FIGURE 13) of I–V curves of a prior art device. This indicates that a larger undistorted output signal can be obtained from the device according to this example than from the prior art device.

Moreover, the individual I–V curves of the device of this example (FIGURE 14) are spaced further apart along the current axis than the I–V curves of the prior art device (FIGURE 13) thus indicating a higher transconductance value for the device of this example than for the prior art device.

Example II

Whereas in Example I, the silicon wafer was P type, and the conductive channel was N type, in this example the semiconductive wafer or slice **10** (FIGURES 1–12) consists of intrinsic silicon having a resistivity of about 100 ohm-cm., and the conductivity modifier diffused into the wafer is an acceptor such as boron. The steps of diffusing the conductivity modifier into selected portions of one wafer face **11** to form a pair of P type source and drain regions **19** and **21** in the wafer, thermally growing a silicon oxide coating **24** on the wafer surface without forming an inversion layer thereon by utilizing pure dry

Figure B.188: Karl Heinz Zaininger invented methods of manufacturing field effect transistors.



3,411,199

7

oxygen as the ambient while heating the wafer, and forming openings **27** and **28** in the silicon oxide coating **24** on said one wafer face **11** entirely within the surface boundary of the acceptor-diffused wafer regions **19** and **21**, are similar to those described in Example I above. The wafer **10** is now heated in an ambient of ozone at a temperature of about 200° C. to 1000° C. to form a thin P type inversion layer **30** beneath the silicon oxide coating on said one wafer face **11**. The P type inversion layer **30** serves as the conductive channel in the device of this example.

Metallic electrodes **41** and **43** are deposited on the two acceptor-diffused regions **19** and **21**. A metallic gate electrode **42** is deposited on the silicon oxide layer **24** between electrodes **41** and **43**. As in Example I, the gate electrode **42** covers only part of the conductive channel **30**, and is offset so that one end of the gate electrode **42** slightly overlaps the source region, while the other end of the gate electrode extends over part of the conductive channel, leaving the remainder of the channel uncovered.

The wafer **10** is now reheated in an ambient of ozone to increase the conductivity of that portion **34** (FIGURE 11) of the channel **30** which is not covered by the electrode **42**.

The subsequent steps of attaching leads **51, 52** and **53** to electrodes **41, 42** and **43** respectively, subdividing the wafer **10** into a plurality of units, and mounting and casing each unit, are similar to those described in connection with Example I.

The process of the foregoing examples may be utilized to fabricate devices with a wide variety of configurations. For example, the electrode configuration of a semiconductor device may be made circular and concentric, so that an annular gate or control electrode surrounds a central drain electrode, while an annular source electrode in turn surrounds the gate electrode. Alternatively, the source and drain electrodes may be made comb-like or interdigitated in form.

An advantage of the various methods of fabricating semiconductor devices described above is that the conductive channel **30** in each unit formed from a particular semiconductive slice exhibits uniform resistivity from unit to unit. Such uniform resistivity enables the production of a large number of devices with uniform and reproducible electrical characteristics.

Another advantage is that the conductive channel thus prepared is relatively thin, and relatively free from traps, so that current through the channel is easily modulated by the applied field generated by biasing the gate electrode.

Another feature of the invention is that the conductivity of the channel **30** may be monitored and adjusted to the desired values prior to completing the fabrication of the device, thus reducing the amount of scrap. If desired, the conductivity of the channel may be continuously monitored while the silicon body is being heated in a hydrogen-containing ambient, so that the process can be stopped when the desired value is obtained for the conductivity of the channel.

Still another advantage is that the method is simple, rapid, and inexpensive as compared to prior art methods for fabricating such conductive channels.

The embodiments described above are by way of illustration and explanation only, but not limitation. Other dense conductive metals such as tungsten, tantalum, and the like may be utilized for the electrodes instead of gold and silver. The conductive metal may be deposited by electroplating, or by electroless plating, instead of by evaporation. Various other modifications may be made by those skilled in the art without departing from the spirit and scope of the invention as described in the specification and the appended claims.

What is claimed is:

1. The method of forming a conductive channel in a crystalline semiconductive body, comprising the steps of:

forming an insulating coating on one face of said body;

8

heating said body in an ambient capable of altering the conductivity of a surface portion thereof to form in said body a conductive channel nuderneath said coating;

depositing a covering metallic electrode on only a portion of said coating, leaving the remaining portion of said coating uncovered; and,

heating said body in an ambient capable of altering the conductivity of that portion of said one face which underlies said coating and is uncovered by said electrode.

2. The method of forming a non-uniform conductive channel in a silicon body, comprising the steps of:

forming an insulating coating on one face of said body by heating said body in a dry oxygen ambient;

heating said body in a reducing ambient to form in said body a conductive channel underneath said coating;

depositing a covering metallic electrode on only a portion of said coating, leaving the remaining portion of said coating uncovered; and,

reheating said body in a reducing ambient to increase the conductivity of that portion of said one face which underlies said coating and is uncovered by said electrode.

3. The method of forming a non-uniform conductive chanel in a monocrystalline silicon wafer, comprising the steps of:

forming a silicon oxide coating on at least one face of said wafer by heating said wafer in a pure dry oxygen ambient;

heating said wafer in an ambient selected from the group consisting of hydrogen and mixtures of hydrogen with nonoxidizing gases to form in said wafer beneath said silicon oxide coating a thin conductive channel immediately adjacent said one face;

depositing a metallic electrode on said silicon oxide coating over a portion only of said conductive channel, leaving the remaining portion of said channel uncovered; and,

reheating said wafer in a hydrogen-containing ambient to increase the conductivity of that portion only of said channel uncovered by said electrode.

4. The method of fabricating a semiconductor device, comprising the steps of:

preparing a high resistivity crystalline semiconductive wafer with two opposing major faces;

depositing an insulating masking coating on at least one said major face;

removing predetermined portions of said coating to expose two spaced areas on said one major face;

forming two spaced low resistivity regions in said wafer immediately adjacent said two exposed spaced areas respectively;

treating said wafer in an ambient capable of altering the conductivity of said one wafer face beneath said coating;

depositing a first conductive electrode on one said exposed area;

depositing a second conductive electrode on the other said exposed area;

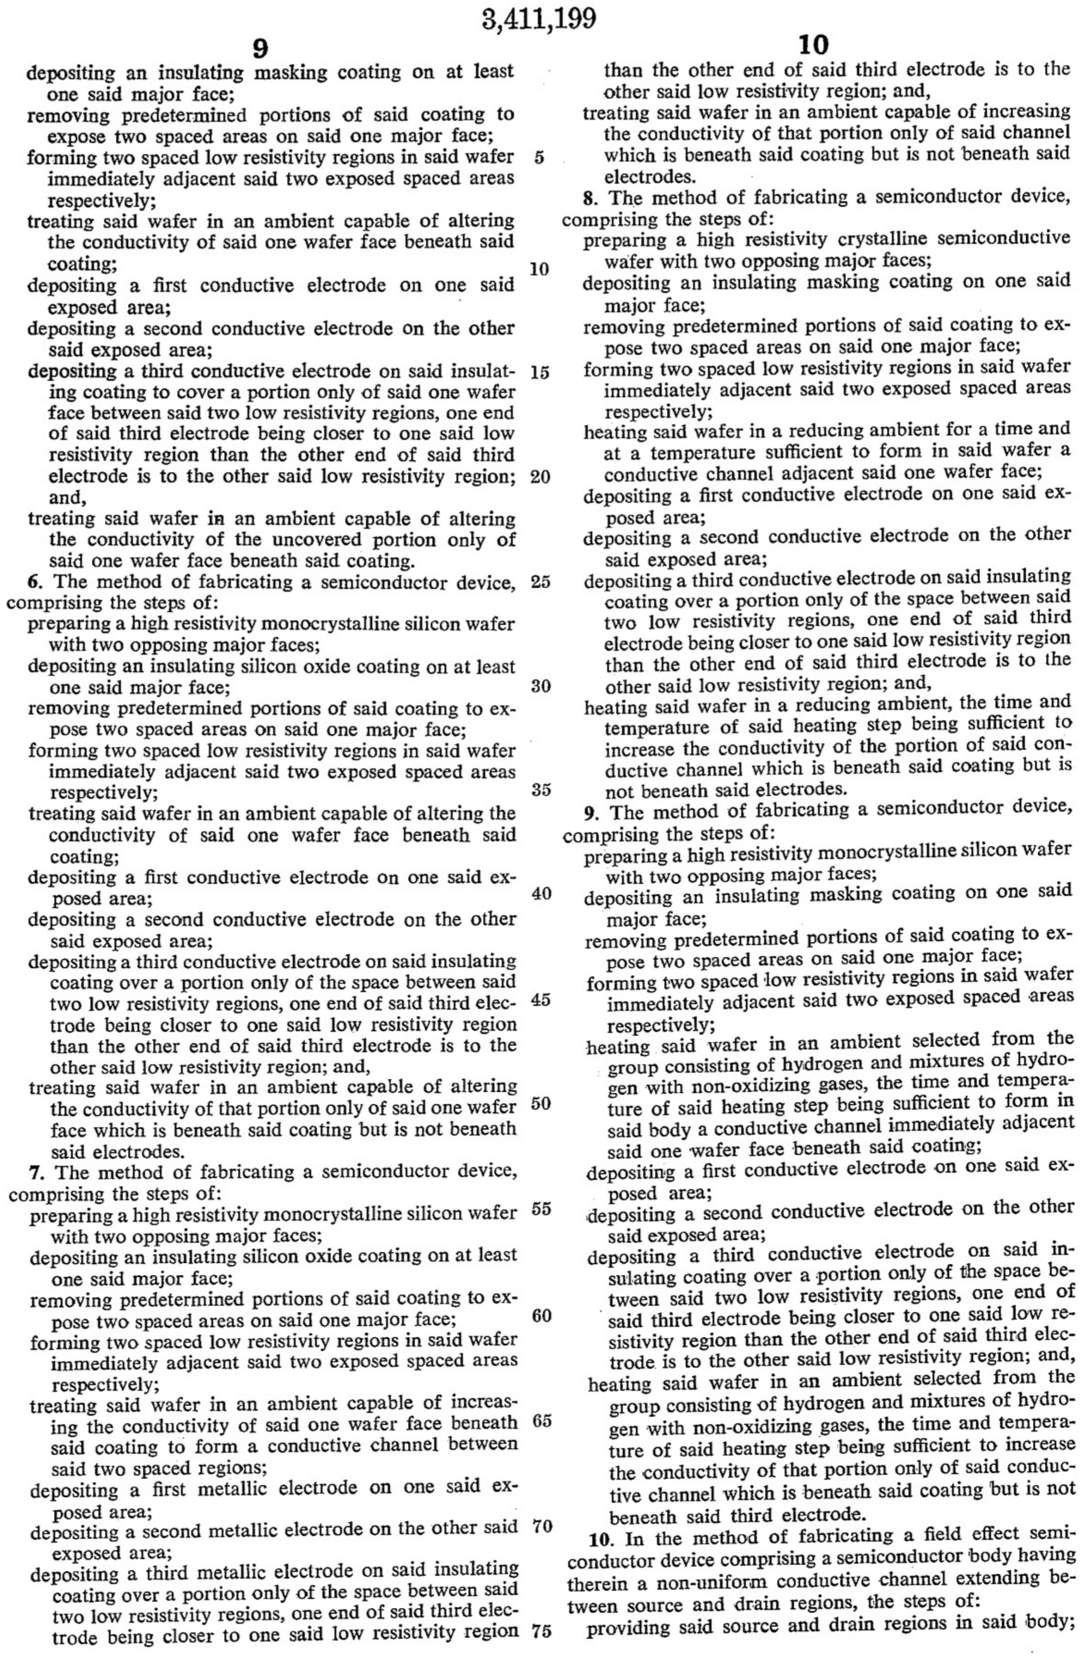
depositing a third conductive electrode on said insulating coating over a portion only of the space between said two low resistivity regions, one end of said third electrode being closer to one said low resistivity region than the other end of said electrode is to the other said low resistivity region; and,

treating said wafer in an ambient capable of altering the conductivity of that portion only of said one wafer face which is beneath said coating but is not beneath said electrodes.

5. The method of fabricating a semiconductor device, comprising the steps of:

preparing a high resistivity crystalline silicon wafer with two opposing major faces;

Figure B.189: Karl Heinz Zaininger invented methods of manufacturing field effect transistors.



3,411,199

9

depositing an insulating masking coating on at least one said major face;

removing predetermined portions of said coating to expose two spaced areas on said one major face;

forming two spaced low resistivity regions in said wafer immediately adjacent said two exposed spaced areas respectively;

treating said wafer in an ambient capable of altering the conductivity of said one wafer face beneath said coating;

depositing a first conductive electrode on one said exposed area;

depositing a second conductive electrode on the other said exposed area;

depositing a third conductive electrode on said insulating coating to cover a portion only of said one wafer face between said two low resistivity regions, one end of said third electrode being closer to one said low resistivity region than the other end of said third electrode is to the other said low resistivity region; and,

treating said wafer in an ambient capable of altering the conductivity of the uncovered portion only of said one wafer face beneath said coating.

6. The method of fabricating a semiconductor device, comprising the steps of:

preparing a high resistivity monocrystalline silicon wafer with two opposing major faces;

depositing an insulating silicon oxide coating on at least one said major face;

removing predetermined portions of said coating to expose two spaced areas on said one major face;

forming two spaced low resistivity regions in said wafer immediately adjacent said two exposed spaced areas respectively;

treating said wafer in an ambient capable of altering the conductivity of said one wafer face beneath said coating;

depositing a first conductive electrode on one said exposed area;

depositing a second conductive electrode on the other said exposed area;

depositing a third conductive electrode on said insulating coating over a portion only of the space between said two low resistivity regions, one end of said third electrode being closer to one said low resistivity region than the other end of said third electrode is to the other said low resistivity region; and,

treating said wafer in an ambient capable of altering the conductivity of that portion only of said one wafer face which is beneath said coating but is not beneath said electrodes.

7. The method of fabricating a semiconductor device, comprising the steps of:

preparing a high resistivity monocrystalline silicon wafer with two opposing major faces;

depositing an insulating silicon oxide coating on at least one said major face;

removing predetermined portions of said coating to expose two spaced areas on said one major face;

forming two spaced low resistivity regions in said wafer immediately adjacent said two exposed spaced areas respectively;

treating said wafer in an ambient capable of increasing the conductivity of said one wafer face beneath said coating to form a conductive channel between said two spaced regions;

depositing a first metallic electrode on one said exposed area;

depositing a second metallic electrode on the other said exposed area;

depositing a third metallic electrode on said insulating coating over a portion only of the space between said two low resistivity regions, one end of said third electrode being closer to one said low resistivity region

10

than the other end of said third electrode is to the other said low resistivity region; and,

treating said wafer in an ambient capable of increasing the conductivity of that portion only of said channel which is beneath said coating but is not beneath said electrodes.

8. The method of fabricating a semiconductor device, comprising the steps of:

preparing a high resistivity crystalline semiconductive wafer with two opposing major faces;

depositing an insulating masking coating on one said major face;

removing predetermined portions of said coating to expose two spaced areas on said one major face;

forming two spaced low resistivity regions in said wafer immediately adjacent said two exposed spaced areas respectively;

heating said wafer in a reducing ambient for a time and at a temperature sufficient to form in said wafer a conductive channel adjacent said one wafer face;

depositing a first conductive electrode on one said exposed area;

depositing a second conductive electrode on the other said exposed area;

depositing a third conductive electrode on said insulating coating over a portion only of the space between said two low resistivity regions, one end of said third electrode being closer to one said low resistivity region than the other end of said third electrode is to the other said low resistivity region; and,

heating said wafer in a reducing ambient, the time and temperature of said heating step being sufficient to increase the conductivity of the portion of said conductive channel which is beneath said coating but is not beneath said electrodes.

9. The method of fabricating a semiconductor device, comprising the steps of:

preparing a high resistivity monocrystalline silicon wafer with two opposing major faces;

depositing an insulating masking coating on one said major face;

removing predetermined portions of said coating to expose two spaced areas on said one major face;

forming two spaced low resistivity regions in said wafer immediately adjacent said two exposed spaced areas respectively;

heating said wafer in an ambient selected from the group consisting of hydrogen and mixtures of hydrogen with non-oxidizing gases, the time and temperature of said heating step being sufficient to form in said body a conductive channel immediately adjacent said one wafer face beneath said coating;

depositing a first conductive electrode on one said exposed area;

depositing a second conductive electrode on the other said exposed area;

depositing a third conductive electrode on said insulating coating over a portion only of the space between said two low resistivity regions, one end of said third electrode being closer to one said low resistivity region than the other end of said third electrode is to the other said low resistivity region; and,

heating said wafer in an ambient selected from the group consisting of hydrogen and mixtures of hydrogen with non-oxidizing gases, the time and temperature of said heating step being sufficient to increase the conductivity of that portion only of said conductive channel which is beneath said coating but is not beneath said third electrode.

ABSTRACT OF THE DISCLOSURE

Aluminum oxide, made by depositing a layer of metallic aluminum on the surface of a body of semiconductive material and then anodizing the aluminum with ions from an oxygen plasma, is employed as an encapsulating coating and as an insulating layer in a semiconductor device. Active devices formed in the semiconductive material adjacent to the coated surface are stable and radiation resistant.

BACKGROUND OF THE INVENTION

This invention relates to semiconductor devices and to methods for their fabrication. More particularly, the invention pertains to semiconductor devices which have insulating coatings thereon, and to methods for producing such coatings.

It is common practice in the semiconductor art to coat semiconductive materials such as silicon, germanium, or gallium arsenide with genetically-derived oxides of the semiconductive material itself, or with oxides deposited by the pyrolytic decomposition of a source material. Aluminum oxide, as a semiconductor coating material, has been formed by depositing a layer of aluminum on a surface of the semiconductor and anodizing the aluminum in a liquid electrolyte.

In integrated circuits of the monolithic type and in discrete active devices, an oxide coating is used as an encapsulating medium to prevent migration of contaminants from the surrounding ambient into the semiconductive material and as an insulating support on which interconnection metallization may be placed. In insulated gate field effect transistors, which are usually fabricated from silicon, thermally-grown silicon dioxide is commonly used as the gate insulator and deposited or thermally-grown silicon dioxide is employed for protection of the device from the ambient.

Careful fabrication techniques have heretofore been required to produce oxide coatings which do not result in surface state problems in the semiconductive material adjacent to the oxide. Lack of cleanliness in the manufacture of silicon field effect devices in which the gate insulator is thermally-grown SiO_2 has resulted in devices which are unstable. These devices, even if made under clean conditions, have low radiation tolerances. Enhancement type field effect devices made under insufficiently clean conditions have had relatively high threshold voltages.

The wet-anodized aluminum oxide mentioned above is not satisfactory as a semiconductor coating because, among other things, charged contaminants such as sodium ions are introduced into the oxide during its formation. These contaminants are mobile and can move under the influence of heat and electric fields, thereby producing changes in the electrical characteristics of devices adjacent to the oxide.

SUMMARY OF THE INVENTION

The present novel semiconductor device is characterized by being coated with aluminum oxide produced by depositing a coating of metallic aluminum on the surface of the semiconductive material and then anodizing this coating, throughout the thickness of the aluminum layer, in an oxygen plasma.

It has been found that devices having coatings produced in this way are stable and resistant to radiation. The semiconductive material beneath the coating exhibits low surface state density and is well shielded against the ambient. Insulated gate field effect devices employing the novel aluminum oxide coating as the gate insulator thereof have relatively low threshold voltages, and are therefore particularly suitable for integrated circuit applications, because the reduction in threshold voltage lowers the power dissipation of the circuit. These devices are also particularly stable under conditions of applied bias and high temperature.

A particular advantage of the present novel method is that the ultraclean fabrication methods now commonly employed in the semiconductor art are not required. Consequently, increased yield arises from a manufacturing operation which uses this method.

THE DRAWINGS

FIG. 1 is a plan view of a portion of an integrated circuit which employs the present novel aluminum oxide coating in several ways;

FIG. 2 is a cross section taken on the line **2—2** of FIG. 1;

FIG. 3 is a perspective view of apparatus useful in carrying out the present novel method;

FIG. 4 is a plan view illustrating some other relationships of the present aluminum oxide coating in integrated circuits;

FIG. 5 is a cross section taken on line **5—5** of FIG. 4;

FIG. 6 is a cross section taken on the line **6—6** of FIG. 4; and

FIG. 7 is a cross sectional view through an insulated gate field effect device employing the present novel aluminum oxide coating as the gate insulator thereof.

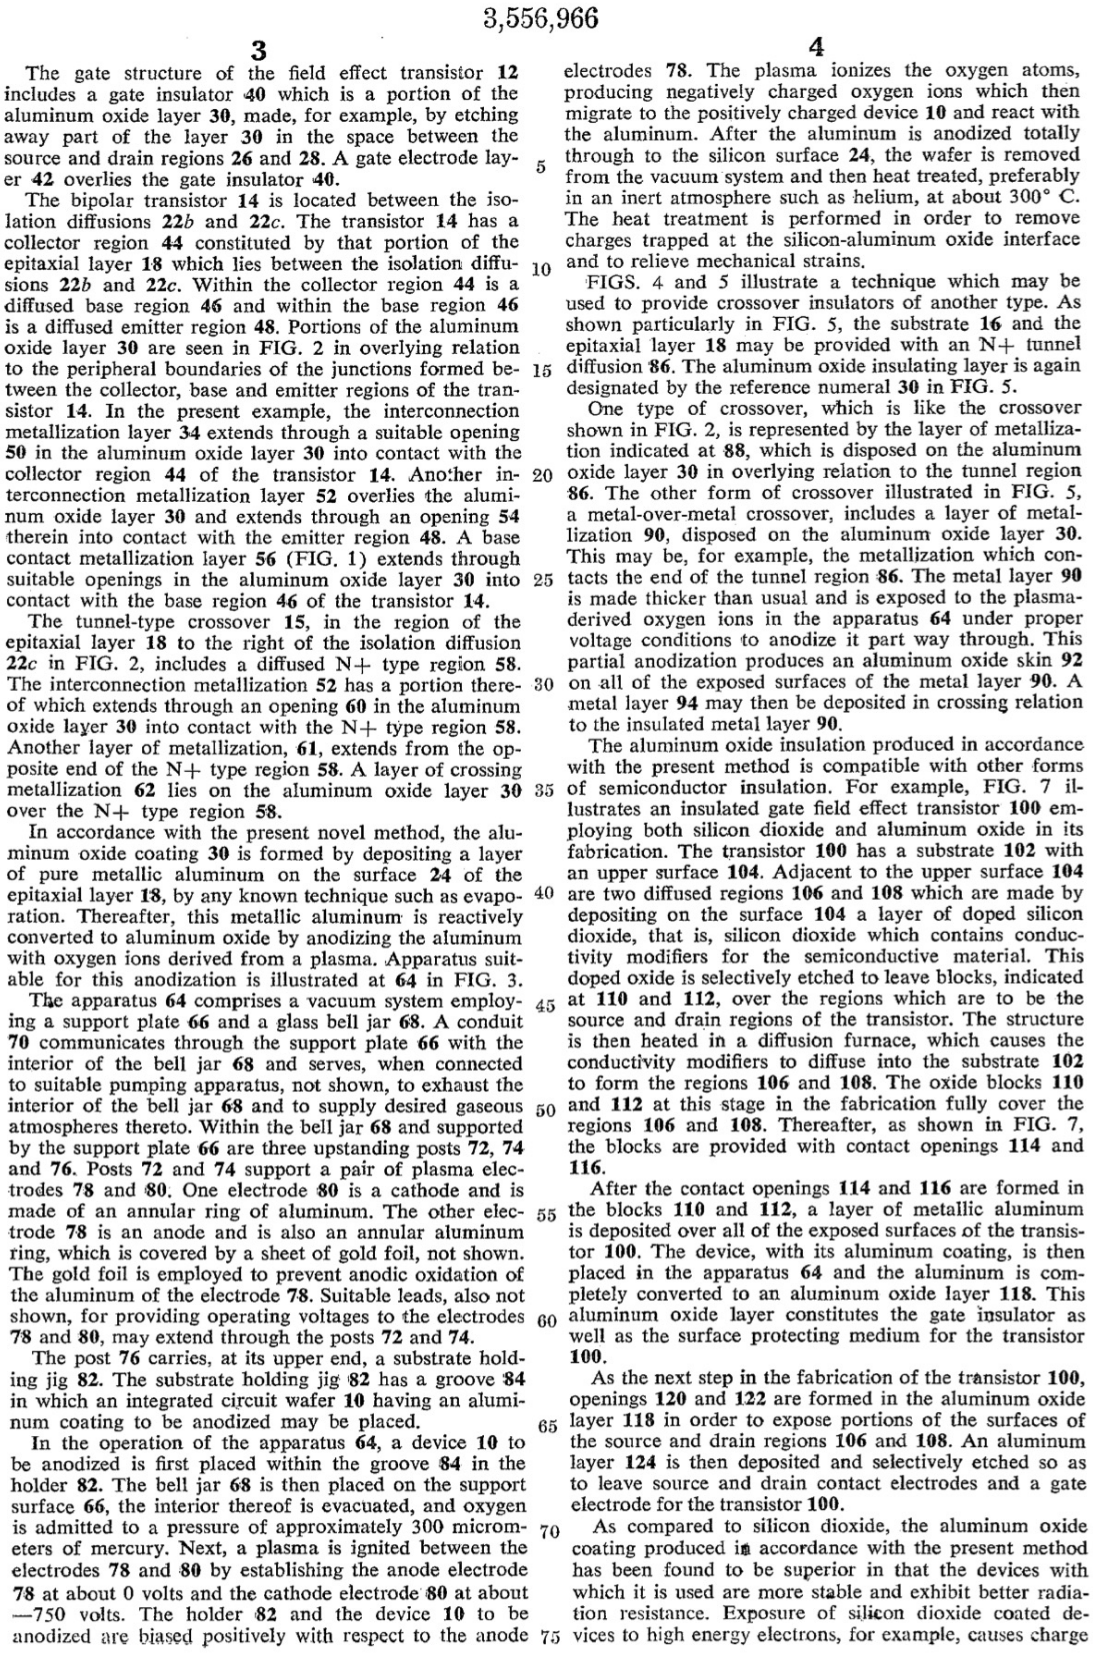
THE PREFERRED EMBODIMENTS

FIGS. 1 and 2 illustrate a portion of an integrated circuit **10** which includes an aluminum oxide coating made by the present novel method. In this example, the integrated circuit **10** has three circuit elements in the portion illustrated in FIG. 1, namely, an insulated gate field effect transistor **12**, a bipolar transistor **14**, and a tunnel-type crossover **15**, which appears in the lower right corner of FIG. 1 and at the right side of the integrated circuit **10** as seen in FIG. 2.

The integrated circuit **10** is fabricated in a wafer **16** of semiconductive material such as silicon, which, in this example, is of P type conductivity. An N type epitaxial layer **18** is disposed on a surface **20** of the wafer **16** and P+ type isolation diffusions **22*a*, 22*b*,** and **22*c*** extend from the upper surface **24** of the epitaxial layer **18** through the epitaxial layer **18** and a short distance into the P type material of the wafer **16.** The techniques for the formation of the epitaxial layer **18** and the P+ isolation diffusions **22*a*, 22*b*,** and **22*c*** are well-known in the art.

The insulated gate field effect transistor **12** has a substrate region formed by that portion of the N type epitaxial layer **18** which lies between the isolation diffusions **22*a*** and **22*b*.** Within this region are two spaced P+ type regions **26** and **28** which constitute source and drain electrode regions respectively, for the transistor **12.** On the surface **24** of the epitaxial layer **18** is a layer **30** of insulating aluminum oxide, made in accordance with the present novel method which will be described in detail hereinafter. Interconnection metallization layers **32** and **34** are disposed on the aluminum oxide layer **30** and have portions which extend through suitable openings **36** and **38** in the aluminum oxide layer **30** into contact with the P+ source and drain regions **26** and **28.**

Figure B.195: Karl Heinz Zaininger invented methods of manufacturing field effect transistors.



The gate structure of the field effect transistor **12** includes a gate insulator **40** which is a portion of the aluminum oxide layer **30**, made, for example, by etching away part of the layer **30** in the space between the source and drain regions **26** and **28**. A gate electrode layer **42** overlies the gate insulator **40**.

The bipolar transistor **14** is located between the isolation diffusions **22*b*** and **22*c***. The transistor **14** has a collector region **44** constituted by that portion of the epitaxial layer **18** which lies between the isolation diffusions **22*b*** and **22*c***. Within the collector region **44** is a diffused base region **46** and within the base region **46** is a diffused emitter region **48**. Portions of the aluminum oxide layer **30** are seen in FIG. 2 in overlying relation to the peripheral boundaries of the junctions formed between the collector, base and emitter regions of the transistor **14**. In the present example, the interconnection metallization layer **34** extends through a suitable opening **50** in the aluminum oxide layer **30** into contact with the collector region **44** of the transistor **14**. Another interconnection metallization layer **52** overlies the aluminum oxide layer **30** and extends through an opening **54** therein into contact with the emitter region **48**. A base contact metallization layer **56** (FIG. 1) extends through suitable openings in the aluminum oxide layer **30** into contact with the base region **46** of the transistor **14**.

The tunnel-type crossover **15**, in the region of the epitaxial layer **18** to the right of the isolation diffusion **22*c*** in FIG. 2, includes a diffused N+ type region **58**. The interconnection metallization **52** has a portion thereof which extends through an opening **60** in the aluminum oxide layer **30** into contact with the N+ type region **58**. Another layer of metallization, **61**, extends from the opposite end of the N+ type region **58**. A layer of crossing metallization **62** lies on the aluminum oxide layer **30** over the N+ type region **58**.

In accordance with the present novel method, the aluminum oxide coating **30** is formed by depositing a layer of pure metallic aluminum on the surface **24** of the epitaxial layer **18**, by any known technique such as evaporation. Thereafter, this metallic aluminum is reactively converted to aluminum oxide by anodizing the aluminum with oxygen ions derived from a plasma. Apparatus suitable for this anodization is illustrated at **64** in FIG. 3.

The apparatus **64** comprises a vacuum system employing a support plate **66** and a glass bell jar **68**. A conduit **70** communicates through the support plate **66** with the interior of the bell jar **68** and serves, when connected to suitable pumping apparatus, not shown, to exhaust the interior of the bell jar **68** and to supply desired gaseous atmospheres thereto. Within the bell jar **68** and supported by the support plate **66** are three upstanding posts **72**, **74** and **76**. Posts **72** and **74** support a pair of plasma electrodes **78** and **80**. One electrode **80** is a cathode and is made of an annular ring of aluminum. The other electrode **78** is an anode and is also an annular aluminum ring, which is covered by a sheet of gold foil, not shown. The gold foil is employed to prevent anodic oxidation of the aluminum of the electrode **78**. Suitable leads, also not shown, for providing operating voltages to the electrodes **78** and **80**, may extend through the posts **72** and **74**.

The post **76** carries, at its upper end, a substrate holding jig **82**. The substrate holding jig **82** has a groove **84** in which an integrated circuit wafer **10** having an aluminum coating to be anodized may be placed.

In the operation of the apparatus **64**, a device **10** to be anodized is first placed within the groove **84** in the holder **82**. The bell jar **68** is then placed on the support surface **66**, the interior thereof is evacuated, and oxygen is admitted to a pressure of approximately 300 micrometers of mercury. Next, a plasma is ignited between the electrodes **78** and **80** by establishing the anode electrode **78** at about 0 volts and the cathode electrode **80** at about —750 volts. The holder **82** and the device **10** to be anodized are biased positively with respect to the anode electrodes **78**. The plasma ionizes the oxygen atoms, producing negatively charged oxygen ions which then migrate to the positively charged device **10** and react with the aluminum. After the aluminum is anodized totally through to the silicon surface **24**, the wafer is removed from the vacuum system and then heat treated, preferably in an inert atmosphere such as helium, at about 300° C. The heat treatment is performed in order to remove charges trapped at the silicon-aluminum oxide interface and to relieve mechanical strains.

FIGS. 4 and 5 illustrate a technique which may be used to provide crossover insulators of another type. As shown particularly in FIG. 5, the substrate **16** and the epitaxial layer **18** may be provided with an N+ tunnel diffusion **86**. The aluminum oxide insulating layer is again designated by the reference numeral **30** in FIG. 5.

One type of crossover, which is like the crossover shown in FIG. 2, is represented by the layer of metallization indicated at **88**, which is disposed on the aluminum oxide layer **30** in overlying relation to the tunnel region **86**. The other form of crossover illustrated in FIG. 5, a metal-over-metal crossover, includes a layer of metallization **90**, disposed on the aluminum oxide layer **30**. This may be, for example, the metallization which contacts the end of the tunnel region **86**. The metal layer **90** is made thicker than usual and is exposed to the plasma-derived oxygen ions in the apparatus **64** under proper voltage conditions to anodize it part way through. This partial anodization produces an aluminum oxide skin **92** on all of the exposed surfaces of the metal layer **90**. A metal layer **94** may then be deposited in crossing relation to the insulated metal layer **90**.

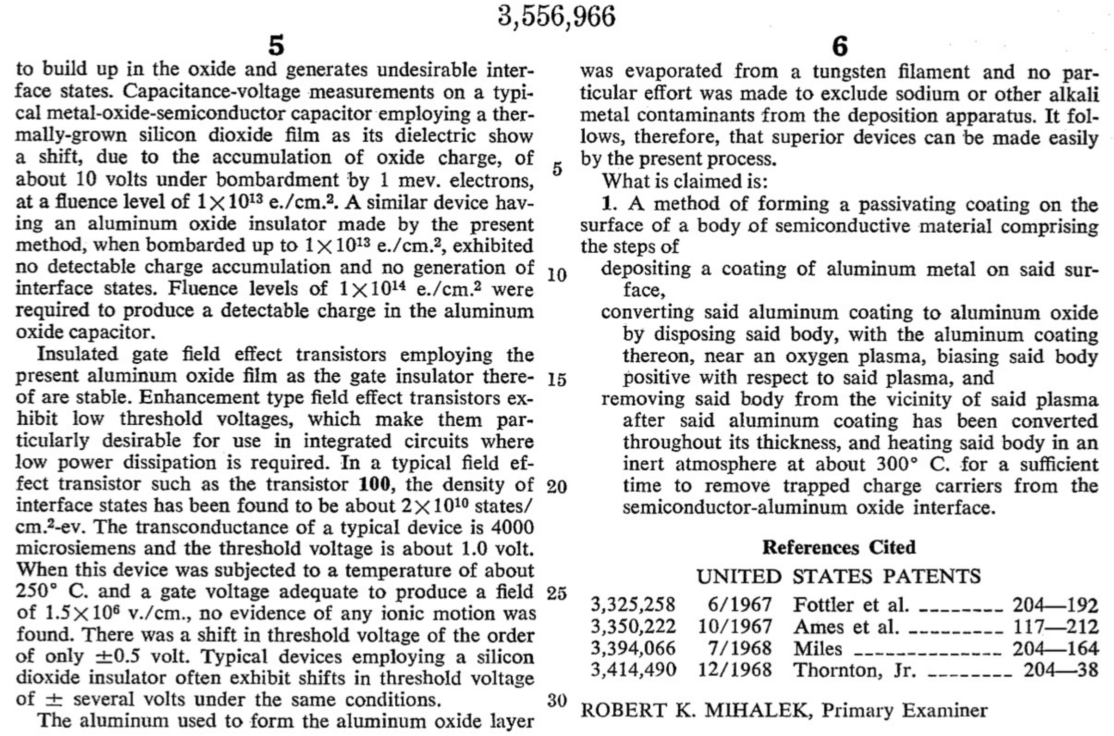
The aluminum oxide insulation produced in accordance with the present method is compatible with other forms of semiconductor insulation. For example, FIG. 7 illustrates an insulated gate field effect transistor **100** employing both silicon dioxide and aluminum oxide in its fabrication. The transistor **100** has a substrate **102** with an upper surface **104**. Adjacent to the upper surface **104** are two diffused regions **106** and **108** which are made by depositing on the surface **104** a layer of doped silicon dioxide, that is, silicon dioxide which contains conductivity modifiers for the semiconductive material. This doped oxide is selectively etched to leave blocks, indicated at **110** and **112**, over the regions which are to be the source and drain regions of the transistor. The structure is then heated in a diffusion furnace, which causes the conductivity modifiers to diffuse into the substrate **102** to form the regions **106** and **108**. The oxide blocks **110** and **112** at this stage in the fabrication fully cover the regions **106** and **108**. Thereafter, as shown in FIG. 7, the blocks are provided with contact openings **114** and **116**.

After the contact openings **114** and **116** are formed in the blocks **110** and **112**, a layer of metallic aluminum is deposited over all of the exposed surfaces of the transistor **100**. The device, with its aluminum coating, is then placed in the apparatus **64** and the aluminum is completely converted to an aluminum oxide layer **118**. This aluminum oxide layer constitutes the gate insulator as well as the surface protecting medium for the transistor **100**.

As the next step in the fabrication of the transistor **100**, openings **120** and **122** are formed in the aluminum oxide layer **118** in order to expose portions of the surfaces of the source and drain regions **106** and **108**. An aluminum layer **124** is then deposited and selectively etched so as to leave source and drain contact electrodes and a gate electrode for the transistor **100**.

As compared to silicon dioxide, the aluminum oxide coating produced in accordance with the present method has been found to be superior in that the devices with which it is used are more stable and exhibit better radiation resistance. Exposure of silicon dioxide coated devices to high energy electrons, for example, causes charge

Figure B.196: Karl Heinz Zaininger invented methods of manufacturing field effect transistors.



to build up in the oxide and generates undesirable interface states. Capacitance-voltage measurements on a typical metal-oxide-semiconductor capacitor employing a thermally-grown silicon dioxide film as its dielectric show a shift, due to the accumulation of oxide charge, of about 10 volts under bombardment by 1 mev. electrons, at a fluence level of 1×10^{13} e./cm.^{2}. A similar device having an aluminum oxide insulator made by the present method, when bombarded up to 1×10^{13} e./cm.^{2}, exhibited no detectable charge accumulation and no generation of interface states. Fluence levels of 1×10^{14} e./cm.^{2} were required to produce a detectable charge in the aluminum oxide capacitor.

Insulated gate field effect transistors employing the present aluminum oxide film as the gate insulator thereof are stable. Enhancement type field effect transistors exhibit low threshold voltages, which make them particularly desirable for use in integrated circuits where low power dissipation is required. In a typical field effect transistor such as the transistor **100**, the density of interface states has been found to be about 2×10^{10} states/cm.^{2}-ev. The transconductance of a typical device is 4000 microsiemens and the threshold voltage is about 1.0 volt. When this device was subjected to a temperature of about 250° C. and a gate voltage adequate to produce a field of 1.5×10^6 v./cm., no evidence of any ionic motion was found. There was a shift in threshold voltage of the order of only ±0.5 volt. Typical devices employing a silicon dioxide insulator often exhibit shifts in threshold voltage of ± several volts under the same conditions.

The aluminum used to form the aluminum oxide layer was evaporated from a tungsten filament and no particular effort was made to exclude sodium or other alkali metal contaminants from the deposition apparatus. It follows, therefore, that superior devices can be made easily by the present process.

What is claimed is:

1. A method of forming a passivating coating on the surface of a body of semiconductive material comprising the steps of

depositing a coating of aluminum metal on said surface,

converting said aluminum coating to aluminum oxide by disposing said body, with the aluminum coating thereon, near an oxygen plasma, biasing said body positive with respect to said plasma, and

removing said body from the vicinity of said plasma after said aluminum coating has been converted throughout its thickness, and heating said body in an inert atmosphere at about 300° C. for a sufficient time to remove trapped charge carriers from the semiconductor-aluminum oxide interface.

[57] **ABSTRACT**

An identification system comprises a number of freely transportable identificands carrying data to be identified arranged at plural correlation positions, and an identifier cooperable with the identificands, when inserted into the identifier, to check the identity of a user of an identificand. A transmitter in the identifier transmits, to the identificand, a number of data, corresponding to the number of correlation positions of the identificand, in succession from the correlation positions. An interpretor is included in the identificand and has input and output terminals, and a selector device in the identificand supplies the transmitted data to the input terminals of the interpreter. A transmitter in the identificand is modulated from the output terminals of the interpreter and transmits the resultant modulated signals to the identifier for processing and evaluation. The identificands may be in the form of flat cards carrying one or more rotatable wheels having numbers around their periphery. The numbers are normally concealed, but the user may, when ready to use the identificand, set one or more wheels to the desired number. When the identificand is inserted into the identifier, the identifier rotates the wheel or wheels back to the zero position to provide a number of pulses corresponding to the preset number on the wheel or wheels. Each card contains integrated circuits providing safety against falsification, and the identifier has means to detect any tampering with the integrated circuits.

IDENTIFICATION SYSTEM

CROSS-REFERENCE TO RELATED APPLICATION

This application is a continuation-in-part of application Ser. No. 857,957, filed Sept. 15, 1969 for "Identification Switch."

BACKGROUND AND SUMMARY OF THE INVENTION

Copending application Ser. No. 857,957 is directed to an identification switch or system having the function of receiving certain offered information and correlating the same with a certain meaning. The arrangement thus consists, in principle, of two parts, the so-called "identificand," which carries the information, and the "identifier," which contains the evaluating circuit. The data of the various identificands are represented by the various linkages or interconnections of the respective correlator circuit contained in each identificand. The identifier includes a number of sending points and receiving points, between which the identificand establishes connections in accordance with its respective linkages or interconnections. The basic principle of the identifier is that the sending points act on the receiving points of the identifier with defined pulse currents through the linkages or interconnections contained in the identificand, thus storing the code of the identificand therein. The identificand and the identifier each have the same number, for example, 10, of spatially discrete receiving and sending points or positions.

With this arrangement, a parallel input of the interrogating pulses from the identifier, and a parallel output of the identification pulses from the identificand into the identifier is possible. However, the principle of correlation is not limited to the parallel operation or to the spatially discrete sending and receiving points or stations.

As a development of the invention covered by application Ser. No. 857,957, in the present invention, the data arriving from the identifier are supplied successively to the input terminals of the correlator or interpretor and, for this purpose, a suitable selector device is provided in the identificand. Furthermore, the identificand includes a transmitting arrangement whose modulation is determined by the output terminals of the correlator or interpretor, and by means of which the modulation, determined by the correlator or interpretor, is transmitted directly or indirectly to the identifier for processing.

For the distribution of the data, there may be provided, for example in the identifier, a clock providing pulses to successively mark the inputs of the correlator present in the respective identificand. A pulse group, containing a certain number of pulses, is correlated with each output terminal of the correlator or interpretor, so that the successively occurring pulse groups, at these output terminals, represent the code of the respective identificand. The pulse groups are derived by a pulse group generator, which is preset, according to the marked output of the correlator or interpretor, for the generation of the respective pulse group. The successively occurring pulse groups are stored in the identifier directly or coded, so that evaluation can be effected in the identifier.

For the sequential marking of the correlator *pr* interpretor input terminals, there may be provided, in the identificand, a counter which is advanced by the timing pulses of the identifier. The data sent from the identificand to the identifier can be stored in the latter in any suitable form. An advantageous arrangement comprises a matrix memory in which these data can be stored by lines or by columns, at the intersections of respective coordinates of the matrix grid. In this instance, of course, a preceding recoding is also possible, whereby the pulse groups are not stored directly.

In the arrangement shown in application Ser. No. 857,957, an additional integrated circuit is provided to secure against falsification. Since, for the serial evaluation of the present invention, integrated circuits in the identificand are expedient, it is advantageous to design the integrated circuit so that they can be used further for safety from falsification.

2

The transmission of pulses between the identifier and the identificand may be effected in many ways, as already described in application Ser. No. 857,957. Furthermore, the serial input and output of the present application is not limited to inductive transmission of the pulses. In the embodiments of the invention described hereinafter, there is explained, for the input of the pulses from the identifier into the identificand, transmission by means of modulated high frequency through an inductive coupling, while the output is effected directly through direct current pulses, again through an inductive coupling. Instead of this, a capacitive coupling may be used. Also, the modulated high frequency for the input into the identificand may be substituted by a direct pulse transmission process. Finally, the transmission may be effected optically, with a light source being provided in the identifier and a photocell in the identificand. In this case also, a receiving photocell, designed as a solar cell, could, simultaneously, furnish the current supply.

The current supply for the semiconductor circuit of the identificands may be derived from an external high-frequency source, in a manner already known. Alternatively, the current supply could be provided by a thermoelement heated by the identifier, or through a photosensitive solar cell. Finally, the current supply could be derived from the permanent data stroke received from the receiving coil or winding of the identificand, if the modulated interval is bridged by a small charging condenser.

The particular advantage of serial input and output is that only a small number of contact points or positions is needed. Another advantage is that the correlation field can be produced easily by a corresponding program control in the integrated circuit itself, and in such a manner that it differs from one identificand to another.

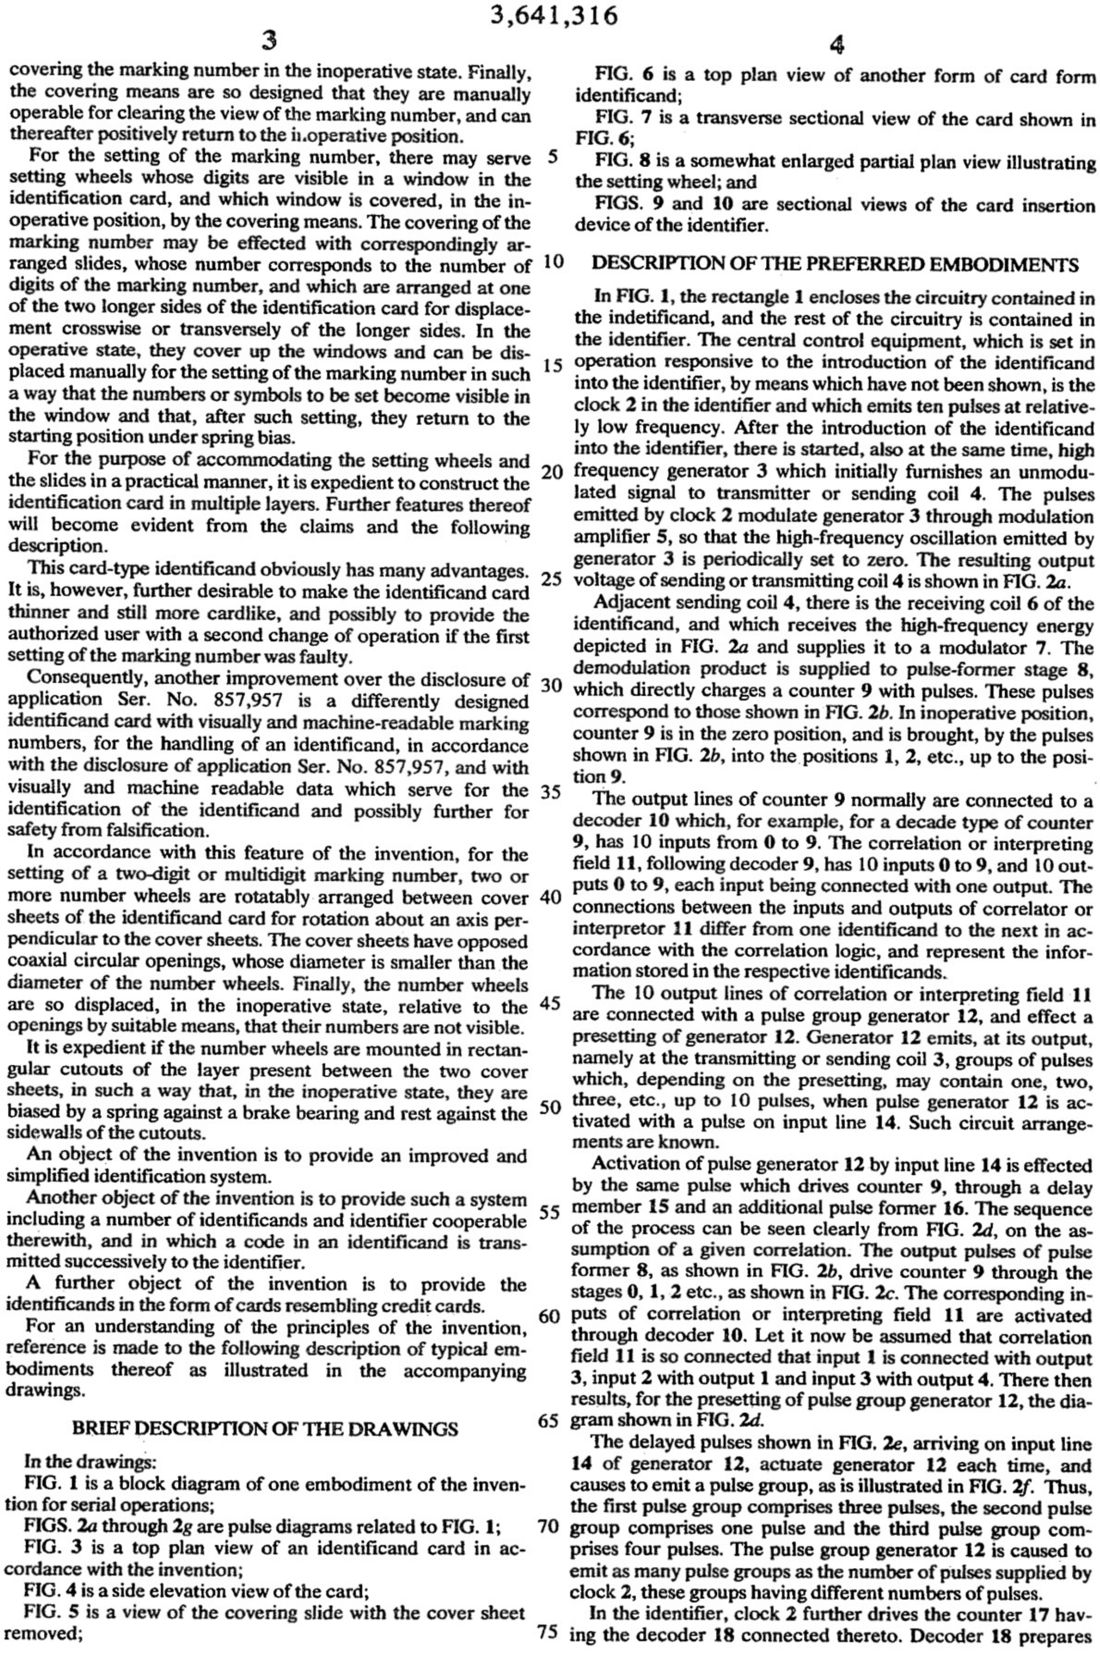
The present improvement over application Ser. No. 857,957 is not limited to the embodiments shown and described. In fact, combinations between the serial solution and the parallel solution are possible, for example, with serial input and parallel output or with parallel input and serial output, as well as arrangements for the input and output that are partly in parallel and partly in series.

The identificands and identifiers of application Ser. No. 857,957 comprise three novel technical features, namely, the correlation logic, the circuit for safety falsification, and the marking number in the identificands. Correlator circuits are known per se. Safety from falsification is attained in that there is provided, in the identificands, a component whose presence can be ascertained clearly by the identifier. This component is a specific integrated circuit, for the imitation of which very extensive manufacturing systems are necessary, so that falsification becomes unprofitable. Since the marking number is lodged in the identificand, rather than in the identifier as in known systems, spying out of the marking number is rendered impossible.

In application Ser. No. 857,957, the identificands are designed as small, key-type slides in which the above named three features are incorporated. In their mechanical construction, the identifiers correspond to this form of identificands. The carrying into effect of the principles mentioned above, however, is not limited to these forms of identificands or identifiers, but can be performed with numerous other forms. Thus, for example, identificands in the form of a pin of square cross section, or in the form which comes very close to the widely used "credit cards" and, at the same time, to arrange the identifiers for checking and for data transfer from these identificands. Accordingly, a further improvement over the disclosure of application Ser. No. 857,957 relates to a new identificand essentially in the form of a "credit card."

In accordance with this feature of the present invention, the identificand, which contains visually and machine-readable data serving for the identification of the identificand and for safety from falsification, is designed in card form. Additionally, there are provided devices for the selective setting of a two-digit or multidigit marking number, and means for

Figure B.203: Helmut Gröttrup and Jürgen Dethloff invented the smart card, or chip card, in 1966. Earlier, Gröttrup developed avionics systems in Germany during the war and led the German-speaking contributions to the postwar Soviet ballistic missile program.



covering the marking number in the inoperative state. Finally, the covering means are so designed that they are manually operable for clearing the view of the marking number, and can thereafter positively return to the inoperative position.

For the setting of the marking number, there may serve setting wheels whose digits are visible in a window in the identification card, and which window is covered, in the inoperative position, by the covering means. The covering of the marking number may be effected with correspondingly arranged slides, whose number corresponds to the number of digits of the marking number, and which are arranged at one of the two longer sides of the identification card for displacement crosswise or transversely of the longer sides. In the operative state, they cover up the windows and can be displaced manually for the setting of the marking number in such a way that the numbers or symbols to be set become visible in the window and that, after such setting, they return to the starting position under spring bias.

For the purpose of accommodating the setting wheels and the slides in a practical manner, it is expedient to construct the identification card in multiple layers. Further features thereof will become evident from the claims and the following description.

This card-type identificand obviously has many advantages. It is, however, further desirable to make the identificand card thinner and still more cardlike, and possibly to provide the authorized user with a second change of operation if the first setting of the marking number was faulty.

Consequently, another improvement over the disclosure of application Ser. No. 857,957 is a differently designed identificand card with visually and machine-readable marking numbers, for the handling of an identificand, in accordance with the disclosure of application Ser. No. 857,957, and with visually and machine readable data which serve for the identification of the identificand and possibly further for safety from falsification.

In accordance with this feature of the invention, for the setting of a two-digit or multidigit marking number, two or more number wheels are rotatably arranged between cover sheets of the identificand card for rotation about an axis perpendicular to the cover sheets. The cover sheets have opposed coaxial circular openings, whose diameter is smaller than the diameter of the number wheels. Finally, the number wheels are so displaced, in the inoperative state, relative to the openings by suitable means, that their numbers are not visible.

It is expedient if the number wheels are mounted in rectangular cutouts of the layer present between the two cover sheets, in such a way that, in the inoperative state, they are biased by a spring against a brake bearing and rest against the sidewalls of the cutouts.

An object of the invention is to provide an improved and simplified identification system.

Another object of the invention is to provide such a system including a number of identificands and identifier cooperable therewith, and in which a code in an identificand is transmitted successively to the identifier.

A further object of the invention is to provide the identificands in the form of cards resembling credit cards.

For an understanding of the principles of the invention, reference is made to the following description of typical embodiments thereof as illustrated in the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

In the drawings:

FIG. **1** is a block diagram of one embodiment of the invention for serial operations;

FIGS. **2***a* through **2***g* are pulse diagrams related to FIG. **1**;

FIG. **3** is a top plan view of an identificand card in accordance with the invention;

FIG. **4** is a side elevation view of the card;

FIG. **5** is a view of the covering slide with the cover sheet removed;

FIG. **6** is a top plan view of another form of card form identificand;

FIG. **7** is a transverse sectional view of the card shown in FIG. **6**;

FIG. **8** is a somewhat enlarged partial plan view illustrating the setting wheel; and

FIGS. **9** and **10** are sectional views of the card insertion device of the identifier.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In FIG. **1**, the rectangle **1** encloses the circuitry contained in the indetificand, and the rest of the circuitry is contained in the identifier. The central control equipment, which is set in operation responsive to the introduction of the identificand into the identifier, by means which have not been shown, is the clock **2** in the identifier and which emits ten pulses at relatively low frequency. After the introduction of the identificand into the identifier, there is started, also at the same time, high frequency generator **3** which initially furnishes an unmodulated signal to transmitter or sending coil **4**. The pulses emitted by clock **2** modulate generator **3** through modulation amplifier **5**, so that the high-frequency oscillation emitted by generator **3** is periodically set to zero. The resulting output voltage of sending or transmitting coil **4** is shown in FIG. **2***a*.

Adjacent sending coil **4**, there is the receiving coil **6** of the identificand, and which receives the high-frequency energy depicted in FIG. **2***a* and supplies it to a modulator **7**. The demodulation product is supplied to pulse-former stage **8**, which directly charges a counter **9** with pulses. These pulses correspond to those shown in FIG. **2***b*. In inoperative position, counter **9** is in the zero position, and is brought, by the pulses shown in FIG. **2***b*, into the positions **1**, **2**, etc., up to the position **9**.

The output lines of counter **9** normally are connected to a decoder **10** which, for example, for a decade type of counter **9**, has 10 inputs from **0** to **9**. The correlation or interpreting field **11**, following decoder **9**, has 10 inputs **0** to **9**, and 10 outputs **0** to **9**, each input being connected with one output. The connections between the inputs and outputs of correlator or interpretor **11** differ from one identificand to the next in accordance with the correlation logic, and represent the information stored in the respective identificands.

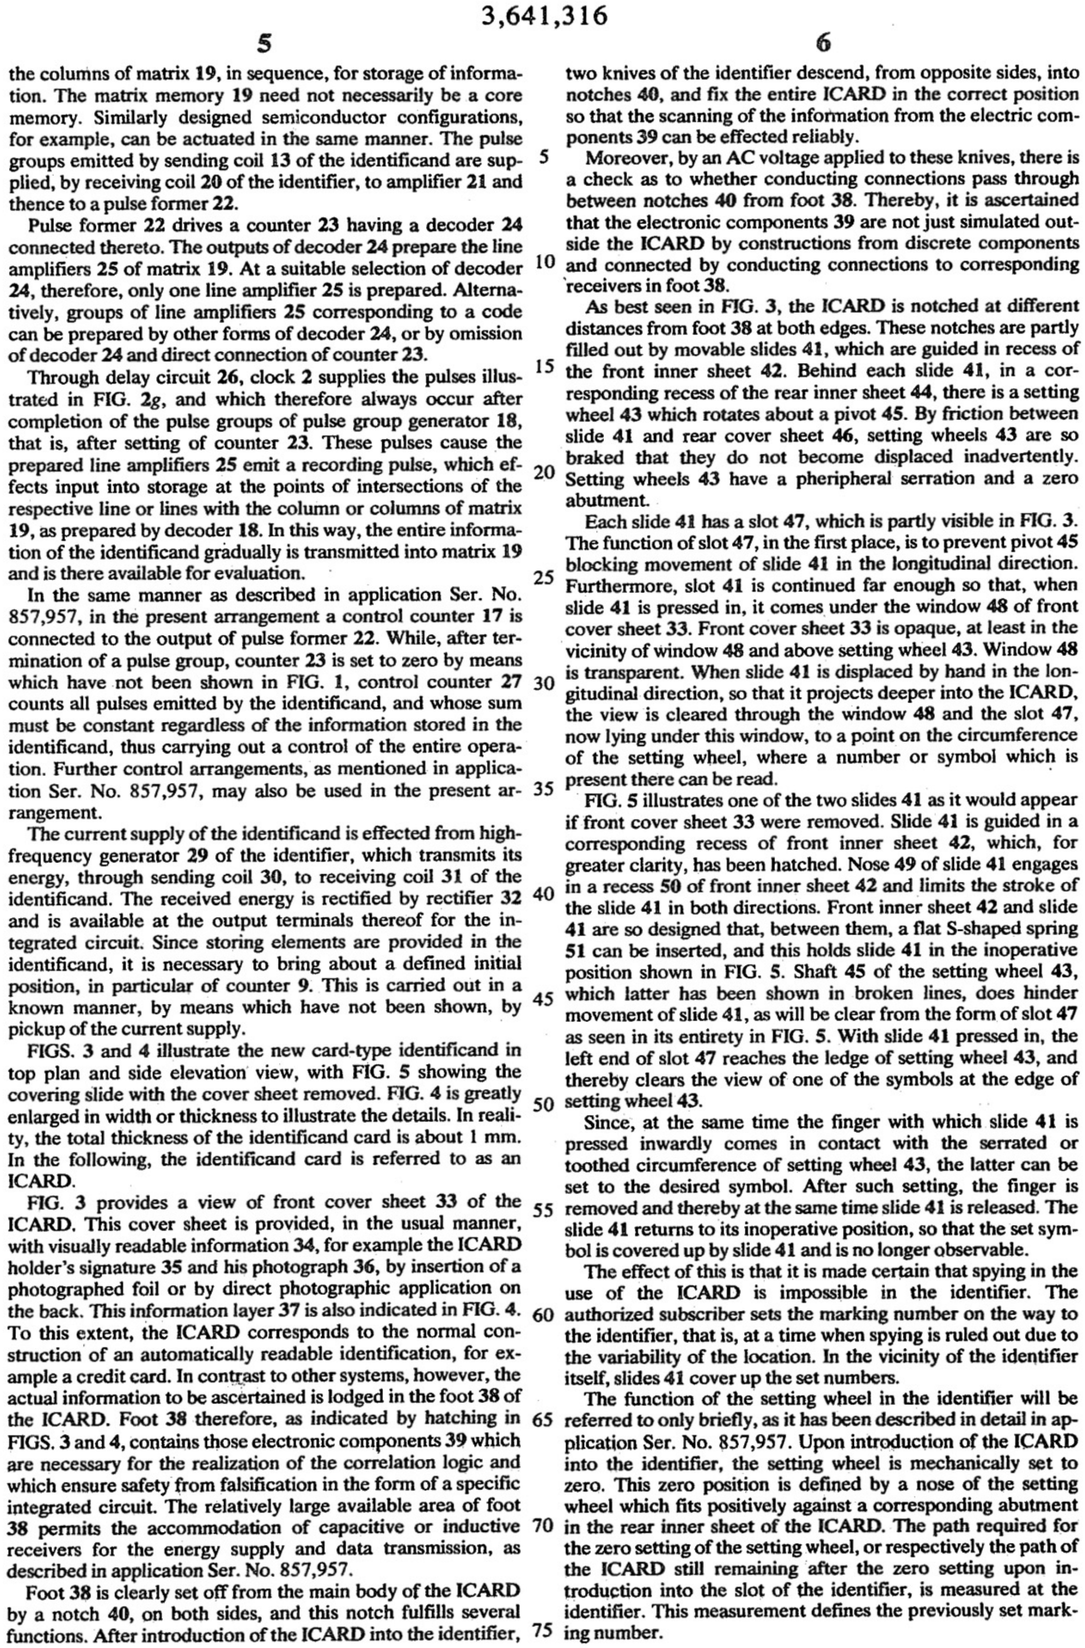
The 10 output lines of correlation or interpreting field **11** are connected with a pulse group generator **12**, and effect a presetting of generator **12**. Generator **12** emits, at its output, namely at the transmitting or sending coil **3**, groups of pulses which, depending on the presetting, may contain one, two, three, etc., up to 10 pulses, when pulse generator **12** is activated with a pulse on input line **14**. Such circuit arrangements are known.

Activation of pulse generator **12** by input line **14** is effected by the same pulse which drives counter **9**, through a delay member **15** and an additional pulse former **16**. The sequence of the process can be seen clearly from FIG. **2***d*, on the assumption of a given correlation. The output pulses of pulse former **8**, as shown in FIG. **2***b*, drive counter **9** through the stages **0**, **1**, **2** etc., as shown in FIG. **2***c*. The corresponding inputs of correlation or interpreting field **11** are activated through decoder **10**. Let it now be assumed that correlation field **11** is so connected that input **1** is connected with output **3**, input **2** with output **1** and input **3** with output **4**. There then results, for the presetting of pulse group generator **12**, the diagram shown in FIG. **2***d*.

The delayed pulses shown in FIG. **2***e*, arriving on input line **14** of generator **12**, actuate generator **12** each time, and causes to emit a pulse group, as is illustrated in FIG. **2***f*. Thus, the first pulse group comprises three pulses, the second pulse group comprises one pulse and the third pulse group comprises four pulses. The pulse group generator **12** is caused to emit as many pulse groups as the number of pulses supplied by clock **2**, these groups having different numbers of pulses.

In the identifier, clock **2** further drives the counter **17** having the decoder **18** connected thereto. Decoder **18** prepares

Figure B.204: Helmut Gröttrup and Jürgen Dethloff invented the smart card, or chip card, in 1966. Earlier, Gröttrup developed avionics systems in Germany during the war and led the German-speaking contributions to the postwar Soviet ballistic missile program.



3,641,316

5 6

the columns of matrix **19**, in sequence, for storage of information. The matrix memory **19** need not necessarily be a core memory. Similarly designed semiconductor configurations, for example, can be actuated in the same manner. The pulse groups emitted by sending coil **13** of the identificand are supplied, by receiving coil **20** of the identifier, to amplifier **21** and thence to a pulse former **22**.

Pulse former **22** drives a counter **23** having a decoder **24** connected thereto. The outputs of decoder **24** prepare the line amplifiers **25** of matrix **19**. At a suitable selection of decoder **24**, therefore, only one line amplifier **25** is prepared. Alternatively, groups of line amplifiers **25** corresponding to a code can be prepared by other forms of decoder **24**, or by omission of decoder **24** and direct connection of counter **23**.

Through delay circuit **26**, clock **2** supplies the pulses illustrated in FIG. **2g**, and which therefore always occur after completion of the pulse groups of pulse group generator **18**, that is, after setting of counter **23**. These pulses cause the prepared line amplifiers **25** emit a recording pulse, which effects input into storage at the points of intersections of the respective line or lines with the column or columns of matrix **19**, as prepared by decoder **18**. In this way, the entire information of the identificand gradually is transmitted into matrix **19** and is there available for evaluation.

In the same manner as described in application Ser. No. 857,957, in the present arrangement a control counter **17** is connected to the output of pulse former **22**. While, after termination of a pulse group, counter **23** is set to zero by means which have not been shown in FIG. **1**, control counter **27** counts all pulses emitted by the identificand, and whose sum must be constant regardless of the information stored in the identificand, thus carrying out a control of the entire operation. Further control arrangements, as mentioned in application Ser. No. 857,957, may also be used in the present arrangement.

The current supply of the identificand is effected from high-frequency generator **29** of the identifier, which transmits its energy, through sending coil **30**, to receiving coil **31** of the identificand. The received energy is rectified by rectifier **32** and is available at the output terminals thereof for the integrated circuit. Since storing elements are provided in the identificand, it is necessary to bring about a defined initial position, in particular of counter **9**. This is carried out in a known manner, by means which have not been shown, by pickup of the current supply.

FIGS. **3** and **4** illustrate the new card-type identificand in top plan and side elevation view, with FIG. **5** showing the covering slide with the cover sheet removed. FIG. **4** is greatly enlarged in width or thickness to illustrate the details. In reality, the total thickness of the identificand card is about 1 mm. In the following, the identificand card is referred to as an ICARD.

FIG. **3** provides a view of front cover sheet **33** of the ICARD. This cover sheet is provided, in the usual manner, with visually readable information **34**, for example the ICARD holder's signature **35** and his photograph **36**, by insertion of a photographed foil or by direct photographic application on the back. This information layer **37** is also indicated in FIG. **4**. To this extent, the ICARD corresponds to the normal construction of an automatically readable identification, for example a credit card. In contrast to other systems, however, the actual information to be ascertained is lodged in the foot **38** of the ICARD. Foot **38** therefore, as indicated by hatching in FIGS. **3** and **4**, contains those electronic components **39** which are necessary for the realization of the correlation logic and which ensure safety from falsification in the form of a specific integrated circuit. The relatively large available area of foot **38** permits the accommodation of capacitive or inductive receivers for the energy supply and data transmission, as described in application Ser. No. 857,957.

Foot **38** is clearly set off from the main body of the ICARD by a notch **40**, on both sides, and this notch fulfills several functions. After introduction of the ICARD into the identifier, two knives of the identifier descend, from opposite sides, into notches **40**, and fix the entire ICARD in the correct position so that the scanning of the information from the electric components **39** can be effected reliably.

Moreover, by an AC voltage applied to these knives, there is a check as to whether conducting connections pass through between notches **40** from foot **38**. Thereby, it is ascertained that the electronic components **39** are not just simulated outside the ICARD by constructions from discrete components and connected by conducting connections to corresponding receivers in foot **38**.

As best seen in FIG. **3**, the ICARD is notched at different distances from foot **38** at both edges. These notches are partly filled out by movable slides **41**, which are guided in recess of the front inner sheet **42**. Behind each slide **41**, in a corresponding recess of the rear inner sheet **44**, there is a setting wheel **43** which rotates about a pivot **45**. By friction between slide **41** and rear cover sheet **46**, setting wheels **43** are so braked that they do not become displaced inadvertently. Setting wheels **43** have a pheripheral serration and a zero abutment.

Each slide **41** has a slot **47**, which is partly visible in FIG. **3**. The function of slot **47**, in the first place, is to prevent pivot **45** blocking movement of slide **41** in the longitudinal direction. Furthermore, slot **41** is continued far enough so that, when slide **41** is pressed in, it comes under the window **48** of front cover sheet **33**. Front cover sheet **33** is opaque, at least in the vicinity of window **48** and above setting wheel **43**. Window **48** is transparent. When slide **41** is displaced by hand in the longitudinal direction, so that it projects deeper into the ICARD, the view is cleared through the window **48** and the slot **47**, now lying under this window, to a point on the circumference of the setting wheel, where a number or symbol which is present there can be read.

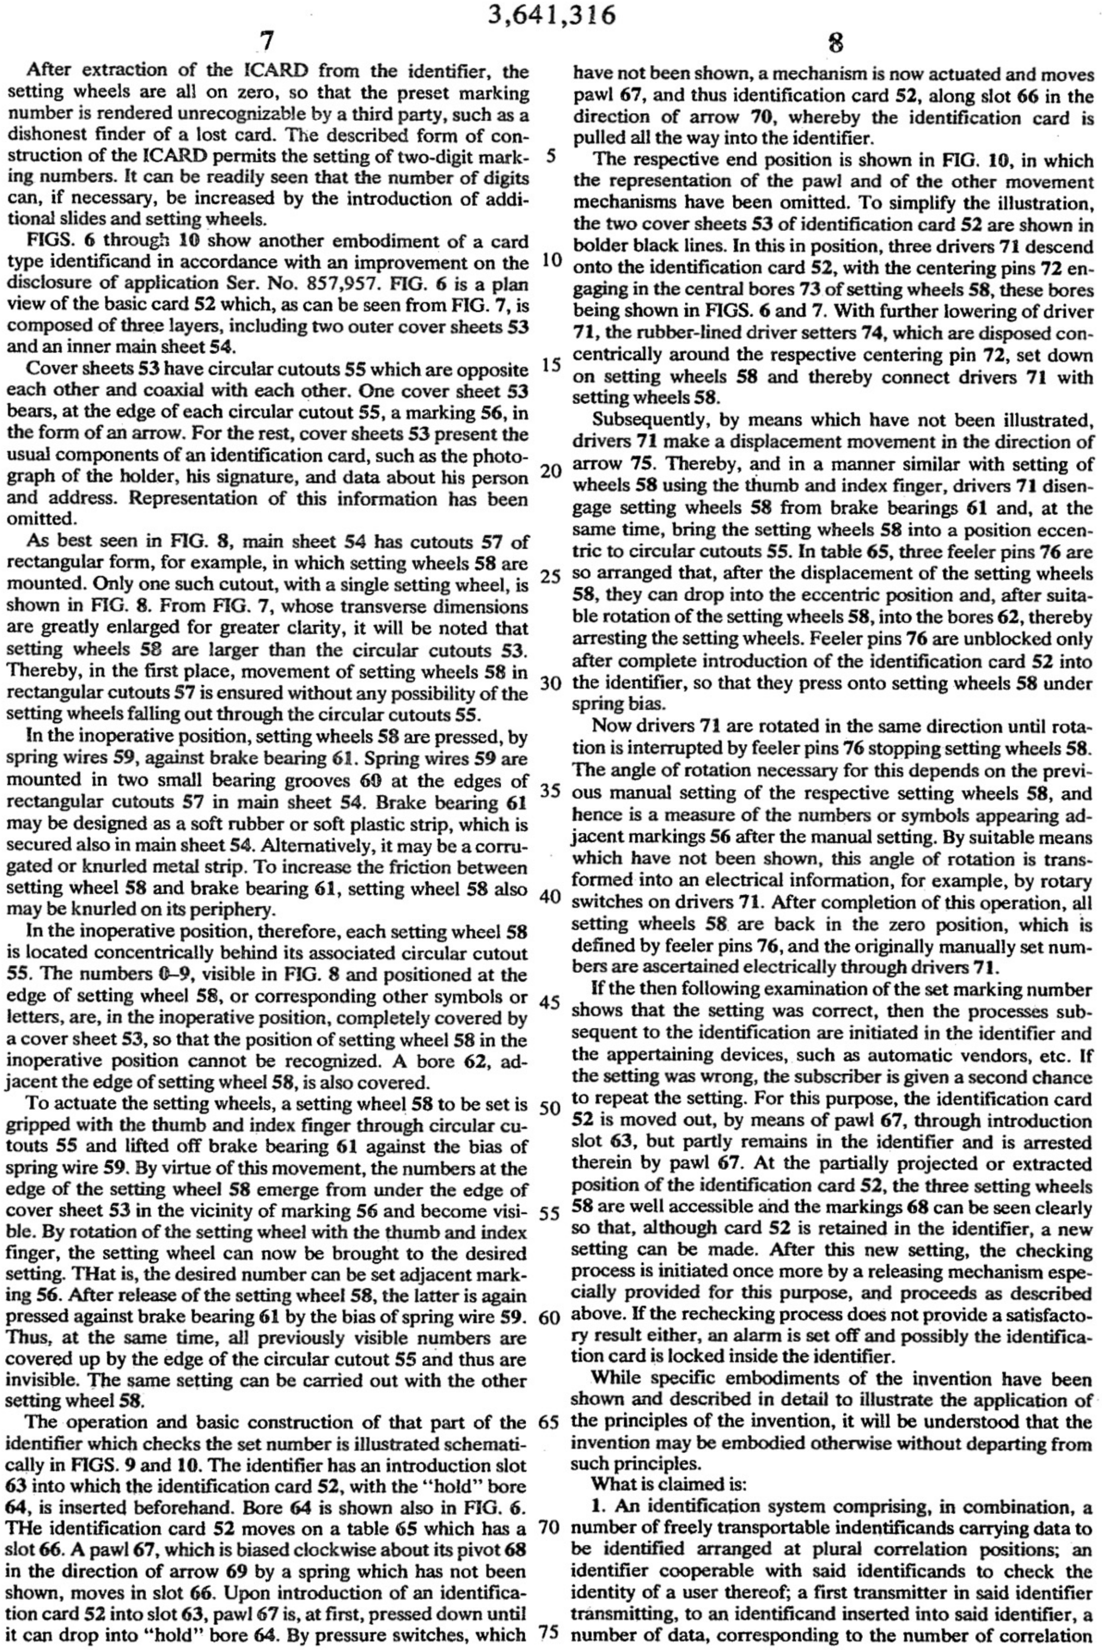
FIG. **5** illustrates one of the two slides **41** as it would appear if front cover sheet **33** were removed. Slide **41** is guided in a corresponding recess of front inner sheet **42**, which, for greater clarity, has been hatched. Nose **49** of slide **41** engages in a recess **50** of front inner sheet **42** and limits the stroke of the slide **41** in both directions. Front inner sheet **42** and slide **41** are so designed that, between them, a flat S-shaped spring **51** can be inserted, and this holds slide **41** in the inoperative position shown in FIG. **5**. Shaft **45** of the setting wheel **43**, which latter has been shown in broken lines, does hinder movement of slide **41**, as will be clear from the form of slot **47** as seen in its entirety in FIG. **5**. With slide **41** pressed in, the left end of slot **47** reaches the ledge of setting wheel **43**, and thereby clears the view of one of the symbols at the edge of setting wheel **43**.

Since, at the same time the finger with which slide **41** is pressed inwardly comes in contact with the serrated or toothed circumference of setting wheel **43**, the latter can be set to the desired symbol. After such setting, the finger is removed and thereby at the same time slide **41** is released. The slide **41** returns to its inoperative position, so that the set symbol is covered up by slide **41** and is no longer observable.

The effect of this is that it is made certain that spying in the use of the ICARD is impossible in the identifier. The authorized subscriber sets the marking number on the way to the identifier, that is, at a time when spying is ruled out due to the variability of the location. In the vicinity of the identifier itself, slides **41** cover up the set numbers.

The function of the setting wheel in the identifier will be referred to only briefly, as it has been described in detail in application Ser. No. 857,957. Upon introduction of the ICARD into the identifier, the setting wheel is mechanically set to zero. This zero position is defined by a nose of the setting wheel which fits positively against a corresponding abutment in the rear inner sheet of the ICARD. The path required for the zero setting of the setting wheel, or respectively the path of the ICARD still remaining after the zero setting upon introduction into the slot of the identifier, is measured at the identifier. This measurement defines the previously set marking number.

Figure B.205: Helmut Gröttrup and Jürgen Dethloff invented the smart card, or chip card, in 1966. Earlier, Gröttrup developed avionics systems in Germany during the war and led the German-speaking contributions to the postwar Soviet ballistic missile program.



3,641,316

7

After extraction of the ICARD from the identifier, the setting wheels are all on zero, so that the preset marking number is rendered unrecognizable by a third party, such as a dishonest finder of a lost card. The described form of construction of the ICARD permits the setting of two-digit marking numbers. It can be readily seen that the number of digits can, if necessary, be increased by the introduction of additional slides and setting wheels.

FIGS. **6** through **10** show another embodiment of a card type identificand in accordance with an improvement on the disclosure of application Ser. No. 857,957. FIG. **6** is a plan view of the basic card **52** which, as can be seen from FIG. **7**, is composed of three layers, including two outer cover sheets **53** and an inner main sheet **54**.

Cover sheets **53** have circular cutouts **55** which are opposite each other and coaxial with each other. One cover sheet **53** bears, at the edge of each circular cutout **55**, a marking **56**, in the form of an arrow. For the rest, cover sheets **53** present the usual components of an identification card, such as the photograph of the holder, his signature, and data about his person and address. Representation of this information has been omitted.

As best seen in FIG. **8**, main sheet **54** has cutouts **57** of rectangular form, for example, in which setting wheels **58** are mounted. Only one such cutout, with a single setting wheel, is shown in FIG. **8**. From FIG. **7**, whose transverse dimensions are greatly enlarged for greater clarity, it will be noted that setting wheels **58** are larger than the circular cutouts **53**. Thereby, in the first place, movement of setting wheels **58** in rectangular cutouts **57** is ensured without any possibility of the setting wheels falling out through the circular cutouts **55**.

In the inoperative position, setting wheels **58** are pressed, by spring wires **59**, against brake bearing **61**. Spring wires **59** are mounted in two small bearing grooves **60** at the edges of rectangular cutouts **57** in main sheet **54**. Brake bearing **61** may be designed as a soft rubber or soft plastic strip, which is secured also in main sheet **54**. Alternatively, it may be a corrugated or knurled metal strip. To increase the friction between setting wheel **58** and brake bearing **61**, setting wheel **58** also may be knurled on its periphery.

In the inoperative position, therefore, each setting wheel **58** is located concentrically behind its associated circular cutout **55**. The numbers **0–9**, visible in FIG. **8** and positioned at the edge of setting wheel **58**, or corresponding other symbols or letters, are, in the inoperative position, completely covered by a cover sheet **53**, so that the position of setting wheel **58** in the inoperative position cannot be recognized. A bore **62**, adjacent the edge of setting wheel **58**, is also covered.

To actuate the setting wheels, a setting wheel **58** to be set is gripped with the thumb and index finger through circular cutouts **55** and lifted off brake bearing **61** against the bias of spring wire **59**. By virtue of this movement, the numbers at the edge of the setting wheel **58** emerge from under the edge of cover sheet **53** in the vicinity of marking **56** and become visible. By rotation of the setting wheel with the thumb and index finger, the setting wheel can now be brought to the desired setting. THat is, the desired number can be set adjacent marking **56**. After release of the setting wheel **58**, the latter is again pressed against brake bearing **61** by the bias of spring wire **59**. Thus, at the same time, all previously visible numbers are covered up by the edge of the circular cutout **55** and thus are invisible. The same setting can be carried out with the other setting wheel **58**.

The operation and basic construction of that part of the identifier which checks the set number is illustrated schematically in FIGS. **9** and **10**. The identifier has an introduction slot **63** into which the identification card **52**, with the "hold" bore **64**, is inserted beforehand. Bore **64** is shown also in FIG. **6**. THe identification card **52** moves on a table **65** which has a slot **66**. A pawl **67**, which is biased clockwise about its pivot **68** in the direction of arrow **69** by a spring which has not been shown, moves in slot **66**. Upon introduction of an identification card **52** into slot **63**, pawl **67** is, at first, pressed down until it can drop into "hold" bore **64**. By pressure switches, which have not been shown, a mechanism is now actuated and moves pawl **67**, and thus identification card **52**, along slot **66** in the direction of arrow **70**, whereby the identification card is pulled all the way into the identifier.

8

The respective end position is shown in FIG. **10**, in which the representation of the pawl and of the other movement mechanisms have been omitted. To simplify the illustration, the two cover sheets **53** of identification card **52** are shown in bolder black lines. In this in position, three drivers **71** descend onto the identification card **52**, with the centering pins **72** engaging in the central bores **73** of setting wheels **58**, these bores being shown in FIGS. **6** and **7**. With further lowering of driver **71**, the rubber-lined driver setters **74**, which are disposed concentrically around the respective centering pin **72**, set down on setting wheels **58** and thereby connect drivers **71** with setting wheels **58**.

Subsequently, by means which have not been illustrated, drivers **71** make a displacement movement in the direction of arrow **75**. Thereby, and in a manner similar with setting of wheels **58** using the thumb and index finger, drivers **71** disengage setting wheels **58** from brake bearings **61** and, at the same time, bring the setting wheels **58** into a position eccentric to circular cutouts **55**. In table **65**, three feeler pins **76** are so arranged that, after the displacement of the setting wheels **58**, they can drop into the eccentric position and, after suitable rotation of the setting wheels **58**, into the bores **62**, thereby arresting the setting wheels. Feeler pins **76** are unblocked only after complete introduction of the identification card **52** into the identifier, so that they press onto setting wheels **58** under spring bias.

Now drivers **71** are rotated in the same direction until rotation is interrupted by feeler pins **76** stopping setting wheels **58**. The angle of rotation necessary for this depends on the previous manual setting of the respective setting wheels **58**, and hence is a measure of the numbers or symbols appearing adjacent markings **56** after the manual setting. By suitable means which have not been shown, this angle of rotation is transformed into an electrical information, for example, by rotary switches on drivers **71**. After completion of this operation, all setting wheels **58** are back in the zero position, which is defined by feeler pins **76**, and the originally manually set numbers are ascertained electrically through drivers **71**.

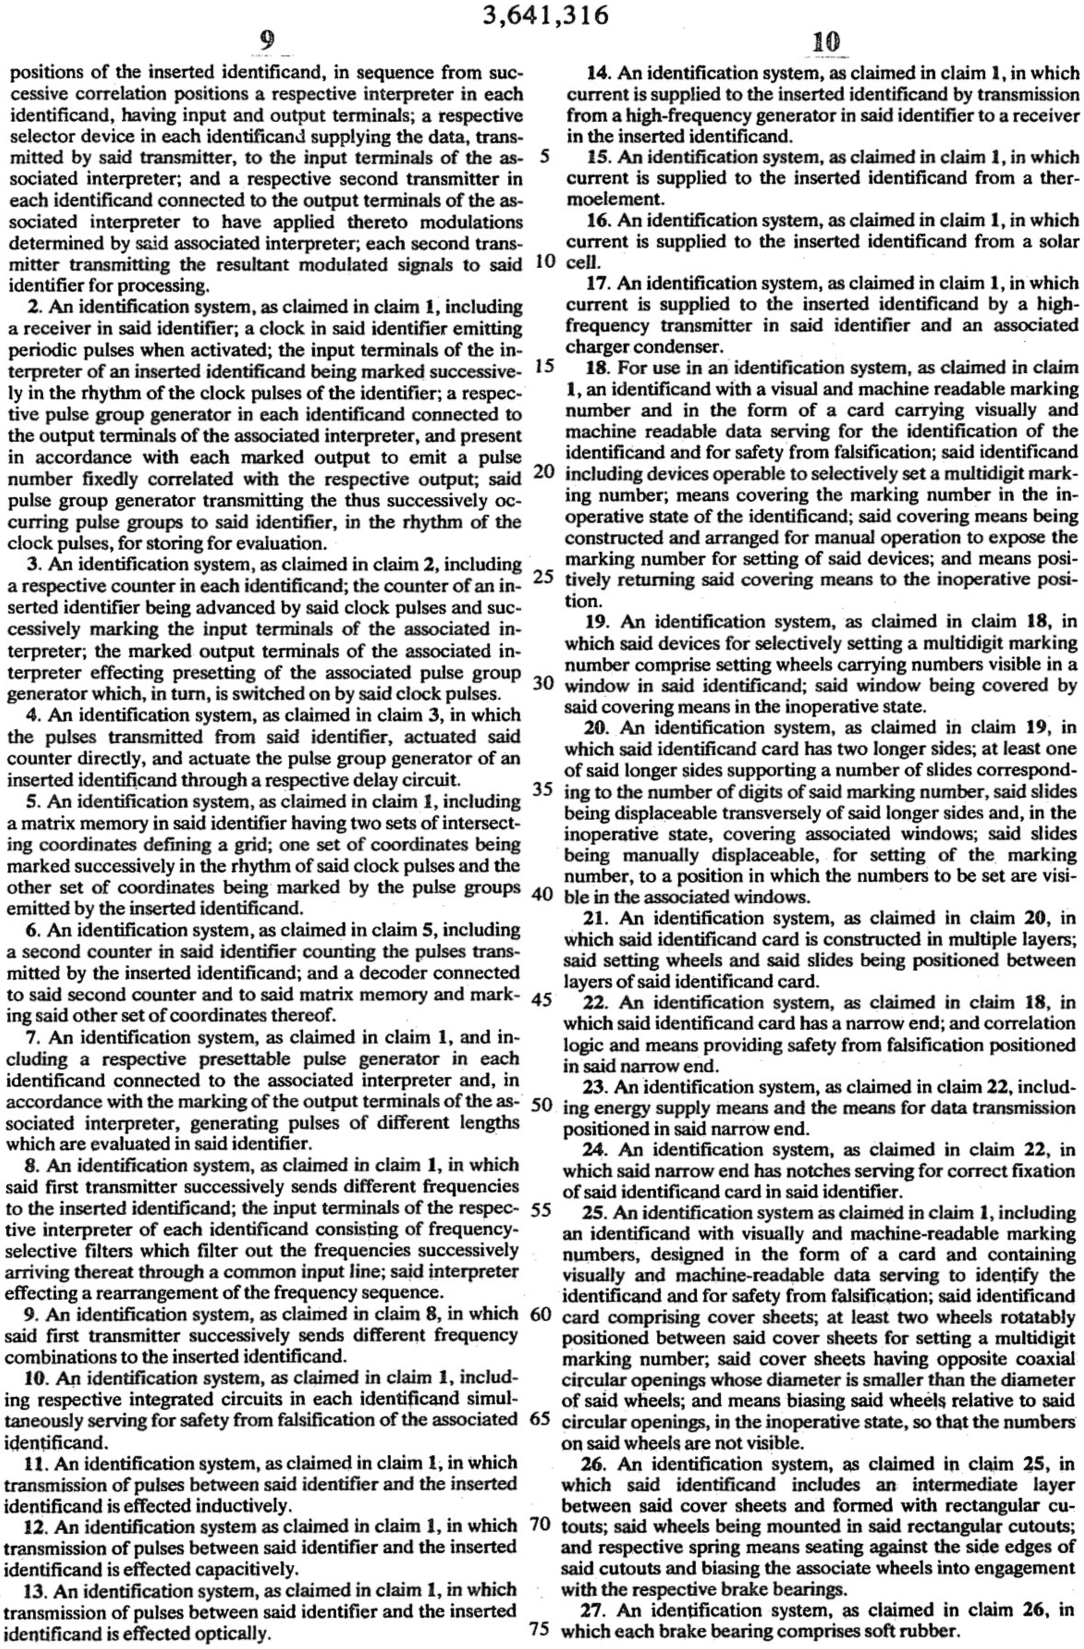
If the then following examination of the set marking number shows that the setting was correct, then the processes subsequent to the identification are initiated in the identifier and the appertaining devices, such as automatic vendors, etc. If the setting was wrong, the subscriber is given a second chance to repeat the setting. For this purpose, the identification card **52** is moved out, by means of pawl **67**, through introduction slot **63**, but partly remains in the identifier and is arrested therein by pawl **67**. At the partially projected or extracted position of the identification card **52**, the three setting wheels **58** are well accessible and the markings **68** can be seen clearly so that, although card **52** is retained in the identifier, a new setting can be made. After this new setting, the checking process is initiated once more by a releasing mechanism especially provided for this purpose, and proceeds as described above. If the rechecking process does not provide a satisfactory result either, an alarm is set off and possibly the identification card is locked inside the identifier.

While specific embodiments of the invention have been shown and described in detail to illustrate the application of the principles of the invention, it will be understood that the invention may be embodied otherwise without departing from such principles.

What is claimed is:

1. An identification system comprising, in combination, a number of freely transportable indentificands carrying data to be identified arranged at plural correlation positions; an identifier cooperable with said identificands to check the identity of a user thereof; a first transmitter in said identifier transmitting, to an identificand inserted into said identifier, a number of data, corresponding to the number of correlation

Figure B.206: Helmut Gröttrup and Jürgen Dethloff invented the smart card, or chip card, in 1966. Earlier, Gröttrup developed avionics systems in Germany during the war and led the German-speaking contributions to the postwar Soviet ballistic missile program.



positions of the inserted identificand, in sequence from successive correlation positions a respective interpreter in each identificand, having input and output terminals; a respective selector device in each identificand supplying the data, transmitted by said transmitter, to the input terminals of the associated interpreter; and a respective second transmitter in each identificand connected to the output terminals of the associated interpreter to have applied thereto modulations determined by said associated interpreter; each second transmitter transmitting the resultant modulated signals to said identifier for processing.

2. An identification system, as claimed in claim **1**, including a receiver in said identifier; a clock in said identifier emitting periodic pulses when activated; the input terminals of the interpreter of an inserted identificand being marked successively in the rhythm of the clock pulses of the identifier; a respective pulse group generator in each identificand connected to the output terminals of the associated interpreter, and present in accordance with each marked output to emit a pulse number fixedly correlated with the respective output; said pulse group generator transmitting the thus successively occurring pulse groups to said identifier, in the rhythm of the clock pulses, for storing for evaluation.

3. An identification system, as claimed in claim **2**, including a respective counter in each identificand; the counter of an inserted identifier being advanced by said clock pulses and successively marking the input terminals of the associated interpreter; the marked output terminals of the associated interpreter effecting presetting of the associated pulse group generator which, in turn, is switched on by said clock pulses.

4. An identification system, as claimed in claim **3**, in which the pulses transmitted from said identifier, actuated said counter directly, and actuate the pulse group generator of an inserted identificand through a respective delay circuit.

5. An identification system, as claimed in claim **1**, including a matrix memory in said identifier having two sets of intersecting coordinates defining a grid; one set of coordinates being marked successively in the rhythm of said clock pulses and the other set of coordinates being marked by the pulse groups emitted by the inserted identificand.

6. An identification system, as claimed in claim **5**, including a second counter in said identifier counting the pulses transmitted by the inserted identificand; and a decoder connected to said second counter and to said matrix memory and marking said other set of coordinates thereof.

7. An identification system, as claimed in claim **1**, and including a respective presettable pulse generator in each identificand connected to the associated interpreter and, in accordance with the marking of the output terminals of the associated interpreter, generating pulses of different lengths which are evaluated in said identifier.

8. An identification system, as claimed in claim **1**, in which said first transmitter successively sends different frequencies to the inserted identificand; the input terminals of the respective interpreter of each identificand consisting of frequency-selective filters which filter out the frequencies successively arriving thereat through a common input line; said interpreter effecting a rearrangement of the frequency sequence.

9. An identification system, as claimed in claim **8**, in which said first transmitter successively sends different frequency combinations to the inserted identificand.

10. An identification system, as claimed in claim **1**, including respective integrated circuits in each identificand simultaneously serving for safety from falsification of the associated identificand.

11. An identification system, as claimed in claim **1**, in which transmission of pulses between said identifier and the inserted identificand is effected inductively.

12. An identification system as claimed in claim **1**, in which transmission of pulses between said identifier and the inserted identificand is effected capacitively.

13. An identification system, as claimed in claim **1**, in which transmission of pulses between said identifier and the inserted identificand is effected optically.

14. An identification system, as claimed in claim **1**, in which current is supplied to the inserted identificand by transmission from a high-frequency generator in said identifier to a receiver in the inserted identificand.

15. An identification system, as claimed in claim **1**, in which current is supplied to the inserted identificand from a thermoelement.

16. An identification system, as claimed in claim **1**, in which current is supplied to the inserted identificand from a solar cell.

17. An identification system, as claimed in claim **1**, in which current is supplied to the inserted identificand by a high-frequency transmitter in said identifier and an associated charger condenser.

18. For use in an identification system, as claimed in claim **1**, an identificand with a visual and machine readable marking number and in the form of a card carrying visually and machine readable data serving for the identification of the identificand and for safety from falsification; said identificand including devices operable to selectively set a multidigit marking number; means covering the marking number in the inoperative state of the identificand; said covering means being constructed and arranged for manual operation to expose the marking number for setting of said devices; and means positively returning said covering means to the inoperative position.

19. An identification system, as claimed in claim **18**, in which said devices for selectively setting a multidigit marking number comprise setting wheels carrying numbers visible in a window in said identificand; said window being covered by said covering means in the inoperative state.

20. An identification system, as claimed in claim **19**, in which said identificand card has two longer sides; at least one of said longer sides supporting a number of slides corresponding to the number of digits of said marking number, said slides being displaceable transversely of said longer sides and, in the inoperative state, covering associated windows; said slides being manually displaceable, for setting of the marking number, to a position in which the numbers to be set are visible in the associated windows.

21. An identification system, as claimed in claim **20**, in which said identificand card is constructed in multiple layers; said setting wheels and said slides being positioned between layers of said identificand card.

22. An identification system, as claimed in claim **18**, in which said identificand card has a narrow end; and correlation logic and means providing safety from falsification positioned in said narrow end.

23. An identification system, as claimed in claim **22**, including energy supply means and the means for data transmission positioned in said narrow end.

24. An identification system, as claimed in claim **22**, in which said narrow end has notches serving for correct fixation of said identificand card in said identifier.

25. An identification system as claimed in claim **1**, including an identificand with visually and machine-readable marking numbers, designed in the form of a card and containing visually and machine-readable data serving to identify the identificand and for safety from falsification; said identificand card comprising cover sheets; at least two wheels rotatably positioned between said cover sheets for setting a multidigit marking number; said cover sheets having opposite coaxial circular openings whose diameter is smaller than the diameter of said wheels; and means biasing said wheels relative to said circular openings, in the inoperative state, so that the numbers on said wheels are not visible.

26. An identification system, as claimed in claim **25**, in which said identificand includes an intermediate layer between said cover sheets and formed with rectangular cutouts; said wheels being mounted in said rectangular cutouts; and respective spring means seating against the side edges of said cutouts and biasing the associate wheels into engagement with the respective brake bearings.

27. An identification system, as claimed in claim **26**, in which each brake bearing comprises soft rubber.

Figure B.207: Helmut Gröttrup and Jürgen Dethloff invented the smart card, or chip card, in 1966. Earlier, Gröttrup developed avionics systems in Germany during the war and led the German-speaking contributions to the postwar Soviet ballistic missile program.

11

28. An identification system, as claimed in claim **26,** in which each brake bearing comprises soft plastic.

29. An identification system, as claimed in claim **26,** in which each brake bearing comprises a metal strip having transversely extending abutments therealong.

30. An identification system, as claimed in claim **29,** in which said wheels have abutments extending transversely of their circular peripheries for engagement with said metal strips.

31. An identification system, as claimed in claim **25,** in which said identificand card is formed with a holding aperture; and a pawl in said identifier engageable in said holding aperture after introduction of the identificand card into said identifier.

32. An identification system, as claimed in claim **26,** in which said wheels have central bores; said identifier having centering pins engageable in said central bores; and driver setters associated with said centering pins and providing for movement of said wheels against the bias of said spring.

12

33. An identification system as claimed in claim **32,** in which each wheel has an eccentric bore; and feeler pins in said identifier engageable in said eccentric bores following eccentric movement of said wheels, to arrest movement of said wheels.

34. An identification system as claimed in claim **33,** in which said identifier comprises electric means operable to determine the angle of rotation of said wheels until rotation thereof is arrested by said feeler pins; said angle depending on the preceding manual setting of said wheels.

35. An identification system as claimed in claim **33,** including means in said identifier operable, after determination of a faulty setting of said marking number, to provide for partial extraction of the identificand card limited by said pawl which prevents complete extraction; and checking means in said identifier operable to trigger an alarm after a faulty marking number has ascertained twice.

B.4 Light Emitting Diodes (LEDs) and Laser Diodes

[German-speaking scientists played leading roles in the development of light emitting diodes (LEDs) and laser diodes. LEDs are much more energy-efficient than incandescent and even fluorescent bulbs, so they are now widely used for everything from illuminated video screens to room lighting. Laser diodes are more compact, rugged, and efficient than most other types of lasers, so they are used for everything from optical disc drives to laser pointers. Both LEDs and laser diodes are utilized in different types of bar code scanners.

Bernhard Gudden (German, 1892–1945) and Robert Pohl (German, 1884–1976) developed and demonstrated the first electroluminescent semiconductor devices, the forerunners of LEDs, during the period 1919–1923 [*Zeitschrift für Physik* 18:1:199–206 (1923)]. They also developed improved photoelectric cells. See pp. 1106 and 2889.

Zoltan Bay (Hungarian, 1900–1992) and György Szigeti (Hungarian, 1905–1978) extended the work of Gudden and Pohl and filed patent applications on true LEDs in 1939, as shown on pp. 2890–2894.

Kurt Lehovec (Bohemian/Austrian/Czech, 1918–2012) worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs, quite possibly based on wartime work. See pp. 1097, 2757–2759, and 2895–2910.

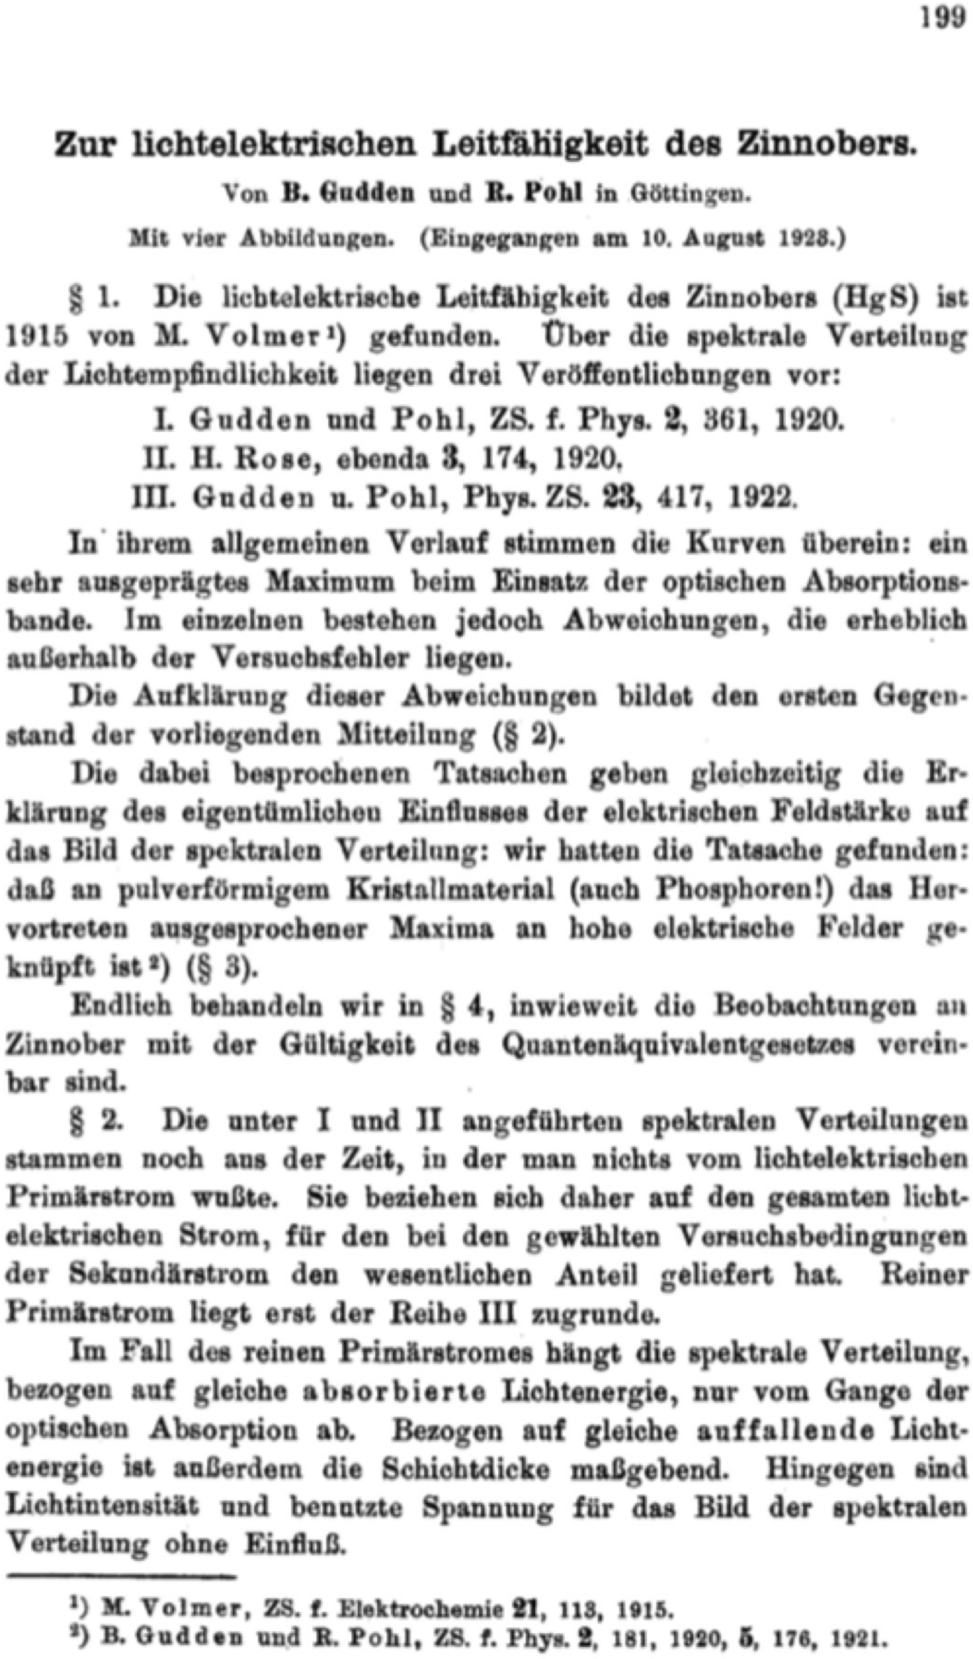
John von Neumann (Hungarian, 1903–1957) made a detailed proposal for laser diodes in 1953, which was likely circulated via his many consulting roles in government and industry, and therefore had a broad and profound influence [*IEEE Journal of Quantum Electronics* 23:6:659–673 (1987)]. See p. 2911.

Walter Heywang (German, 1923–2010) filed detailed patent applications on laser diodes in 1958 (pp. 2912–2916)

Herbert Kroemer (German, 1928–) filed patent applications on the double-heterostructure laser diode in 1963 (pp. 2917–2922). He also invented the drift transistor in 1953 and III-V semiconductor heterostructures in 1966. Kroemer won the Nobel Prize in Physics in 2000 for his innovations in microelectronics (p. 1104).

Other groups produced various types of laser diodes around the same time as Heywang and Kroemer. More archival research is needed to determine whether work in the other laser diode groups was seeded by Heywang's or Kroemer's ideas prior to their formal patent applications, by von Neumann's 1953 proposal, or by other German-speaking work going back to World War II.]

Bernhard Gudden (1892–1945) and Robert Pohl (1884–1976) developed electroluminescent semiconductor devices (1919–1923) [*Zeitschrift für Physik* 18:1:199–206 (1923)]



199

Zur lichtelektrischen Leitfähigkeit des Zinnobers.

Von **B. Gudden** und **R. Pohl** in Göttingen.

Mit vier Abbildungen. (Eingegangen am 10. August 1923.)

§ 1. Die lichtelektrische Leitfähigkeit des Zinnobers (HgS) ist 1915 von M. Volmer[1]) gefunden. Über die spektrale Verteilung der Lichtempfindlichkeit liegen drei Veröffentlichungen vor:

I. Gudden und Pohl, ZS. f. Phys. **2**, 361, 1920.
II. H. Rose, ebenda **3**, 174, 1920.
III. Gudden u. Pohl, Phys. ZS. **23**, 417, 1922.

In ihrem allgemeinen Verlauf stimmen die Kurven überein: ein sehr ausgeprägtes Maximum beim Einsatz der optischen Absorptionsbande. Im einzelnen bestehen jedoch Abweichungen, die erheblich außerhalb der Versuchsfehler liegen.

Die Aufklärung dieser Abweichungen bildet den ersten Gegenstand der vorliegenden Mitteilung (§ 2).

Die dabei besprochenen Tatsachen geben gleichzeitig die Erklärung des eigentümlichen Einflusses der elektrischen Feldstärke auf das Bild der spektralen Verteilung: wir hatten die Tatsache gefunden: daß an pulverförmigem Kristallmaterial (auch Phosphoren!) das Hervortreten ausgesprochener Maxima an hohe elektrische Felder geknüpft ist[2]) (§ 3).

Endlich behandeln wir in § 4, inwieweit die Beobachtungen an Zinnober mit der Gültigkeit des Quantenäquivalentgesetzes vereinbar sind.

§ 2. Die unter I und II angeführten spektralen Verteilungen stammen noch aus der Zeit, in der man nichts vom lichtelektrischen Primärstrom wußte. Sie beziehen sich daher auf den gesamten lichtelektrischen Strom, für den bei den gewählten Versuchsbedingungen der Sekundärstrom den wesentlichen Anteil geliefert hat. Reiner Primärstrom liegt erst der Reihe III zugrunde.

Im Fall des reinen Primärstromes hängt die spektrale Verteilung, bezogen auf gleiche absorbierte Lichtenergie, nur vom Gange der optischen Absorption ab. Bezogen auf gleiche auffallende Lichtenergie ist außerdem die Schichtdicke maßgebend. Hingegen sind Lichtintensität und benutzte Spannung für das Bild der spektralen Verteilung ohne Einfluß.

ELECTRIC SOURCE OF LIGHT

Zoltan Bay, Ujpest, and György Szigeti, Budapest, Hungary, assignors to General Electric Company, a corporation of New York

Application November 12, 1940, Serial No. 365,374
In Hungary October 23, 1939

11 Claims. (Cl. 176—1)

The invention relates to an electric source of light of such kind as converts electrical energy in a direct manner into luminous energy, and in which it is not necessary to cause the light-radiating solid body employed for the production of the light to be heated by means of the current to the temperature required for the emission of any thermal radiation, the radiation of light being obtained instead by utilizing, on the basis of a new phenomenon, certain special properties of the light-radiating body.

The electric sources of light employed up to now for the most part utilize the thermal radiation of solid bodies heated by means of electric current; further, increasing use is being made of the luminous phenomena set up during the passage of electric current through gases, and of the phenomenon of so-called fluorescence, which latter, as well known, consists in the fact that certain substances, under the influence of ultra-violet light or of cathode rays, emit visible light.

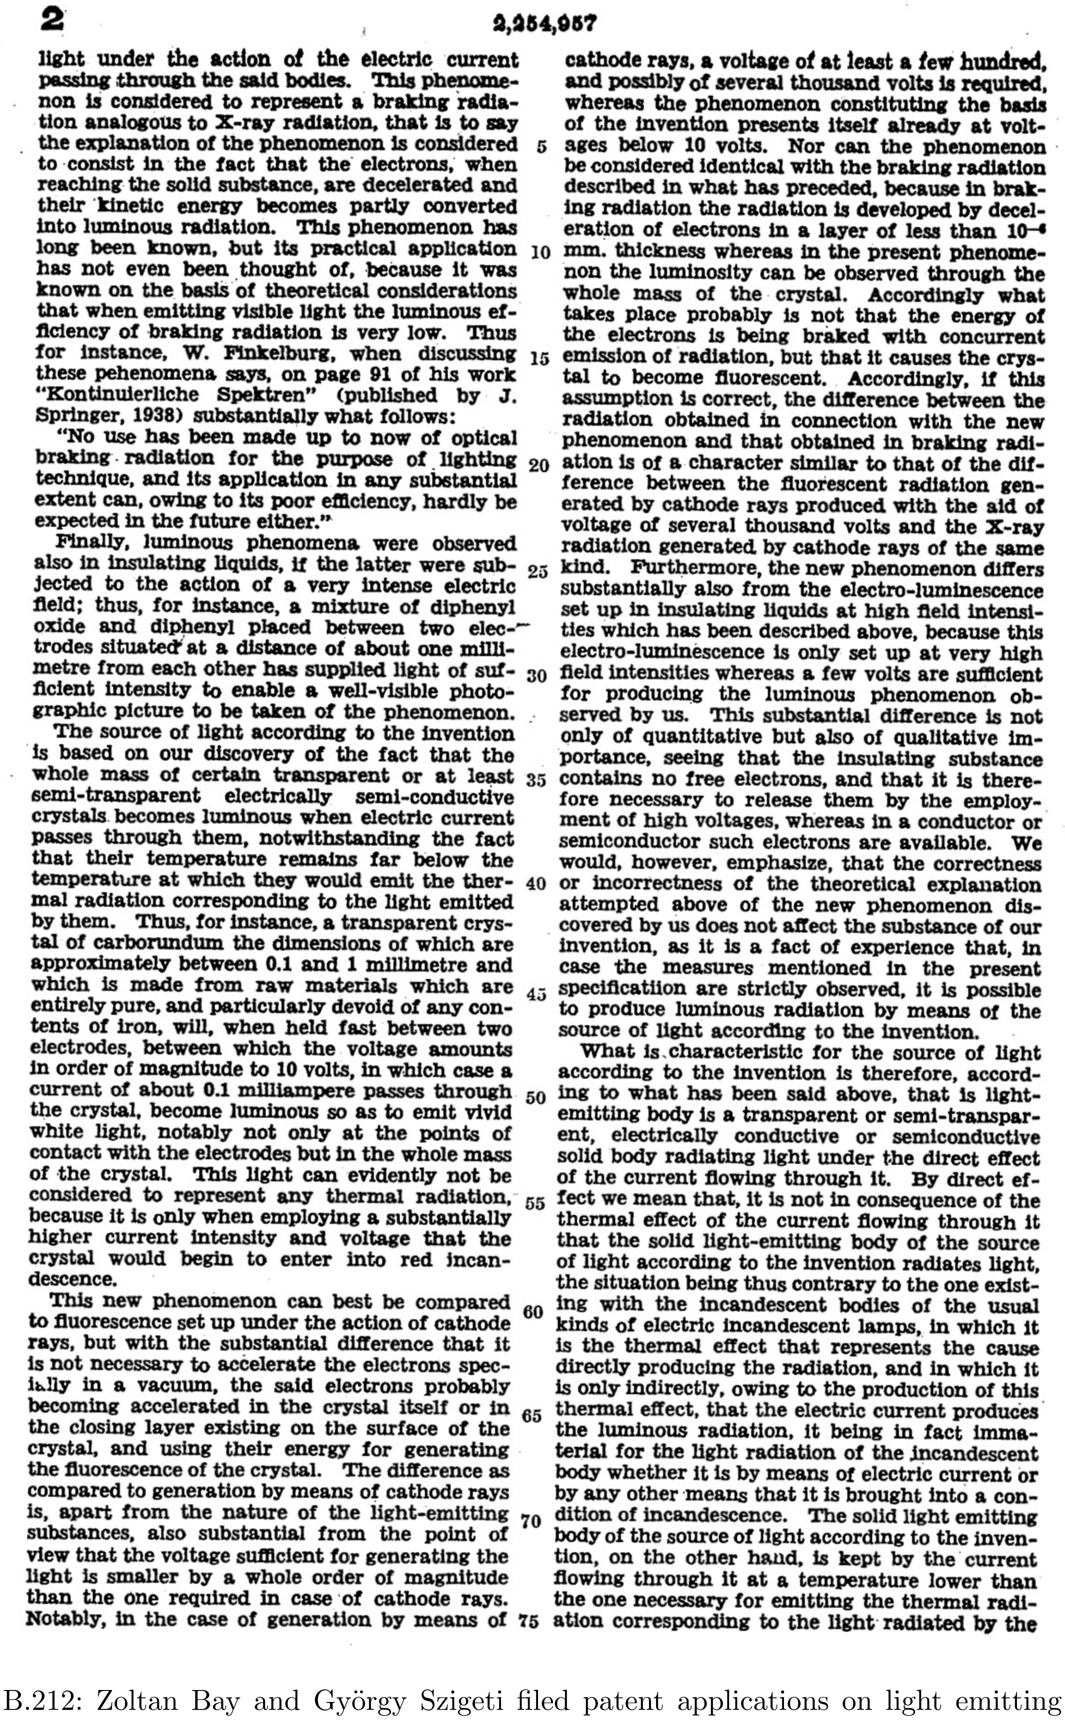
All these sources of light possess certain drawbacks, the most important among which are the following: With electric incandescent lamps or thermal radiators comprising solid incandescent bodies temperatures around 3000° C. were the highest which it has been possible to reach so as to ensure at the same time a satisfactory term of life. Now at this temperature the colour of the luminous radiation is still very far from the colour of the white light corresponding to the colour of sunlight, seeing that the temperature of the sun is about 6500° C. In addition thereto the luminous efficiency of these lamps is, in view of the present degree of development of technical science, unsatisfactory and thus it is mainly to their simplicity, ease of handling and other practical advantages that the wide use made of them is due. As to lamps based on a discharge through gases or vapours, it is a well-known fact that their characteristic is generally negative, because their terminal voltage diminishes with the increase of the intensity of the current passing through them. In order to compensate the negative characteristic, it is, in case of feeding the lamps from sources of energy of constant voltage as generally employed today, e. g. from mains systems, necessary to connect series resistances, choke-coils, reactive transformers, or condensers in series with the lamps, which fact results in a substantial increase of the first cost of the lighting equipment. Moreover, in case of making use of a series resistance the latter will consume unnecessary current, whilst the employment of a choke-coil or reactive transformer will exert a detrimental influence on the phase conditions of the equipment, and condensers can, for practical reasons, not always be employed. A further drawback is constituted by the fact that the ignition voltage of gas discharge lamps is as a rule substantially higher than their operation voltage and that it is therefore either necessary to make provision for special ignition apparatus, or to keep the operation voltage substantially below the mains voltage, either of which arrangements is disadvantageous from an engineering as well as from an economic point of view. Against these drawbacks, however, must be set the advantage, that with lamps of this kind it is possible to obtain luminous efficiencies which are substantially better than those of incandescent lamps. In case of employing fluorescent light the ultra-violet radiation producing such light is as a rule generated by means of a gas-discharge lamp and thus all the drawbacks enumerated above of the latter present themselves. In case of making use of cathode rays it is as a rule necessary to employ very high voltages, in order to ensure the necessary amount of acceleration of the electrons, which circumstance represents a serious drawback in practice and it is only by means of voltages exceeding 1000 volts, with the aid of complicated apparatus and as a rule with an unsatisfactory term of life that satisfactory luminous efficiencies can be obtained.

In addition to these methods actually employed in practice for the production of light, other methods of producing light by means of electric voltages are also known, which methods, however, have, for the reasons which will be clear from what follows, not found any practical employment for the purposes of lighting technique.

Faint luminous phenomena have already been observed on the carborundum crystals of crystal detectors at the point of contact between the needle and the crystal, where minute luminous points have appeared. This phenomenon was interpreted by its first observer as representing a cold electron discharge, the very high field intensity set up at the apex or at the edges of the crystal being sufficient for releasing electrons from the solid substance, which cause an electric gas discharge in the ambient gas or air.

It is also known that the layer formed in certain cases on the surface of electrically semiconductive bodies, as for instance, on the effective surfaces of dry rectifiers, crystal detectors or condensers of the electrolyte type, will emit

Figure B.211: Zoltan Bay and György Szigeti filed patent applications on light emitting diodes (LEDs) in 1939.



2 2,254,957

light under the action of the electric current passing through the said bodies. This phenomenon is considered to represent a braking radiation analogous to X-ray radiation, that is to say the explanation of the phenomenon is considered to consist in the fact that the electrons, when reaching the solid substance, are decelerated and their kinetic energy becomes partly converted into luminous radiation. This phenomenon has long been known, but its practical application has not even been thought of, because it was known on the basis of theoretical considerations that when emitting visible light the luminous efficiency of braking radiation is very low. Thus for instance, W. Finkelburg, when discussing these pehenomena says, on page 91 of his work "Kontinuierliche Spektren" (published by J. Springer, 1938) substantially what follows:

"No use has been made up to now of optical braking radiation for the purpose of lighting technique, and its application in any substantial extent can, owing to its poor efficiency, hardly be expected in the future either."

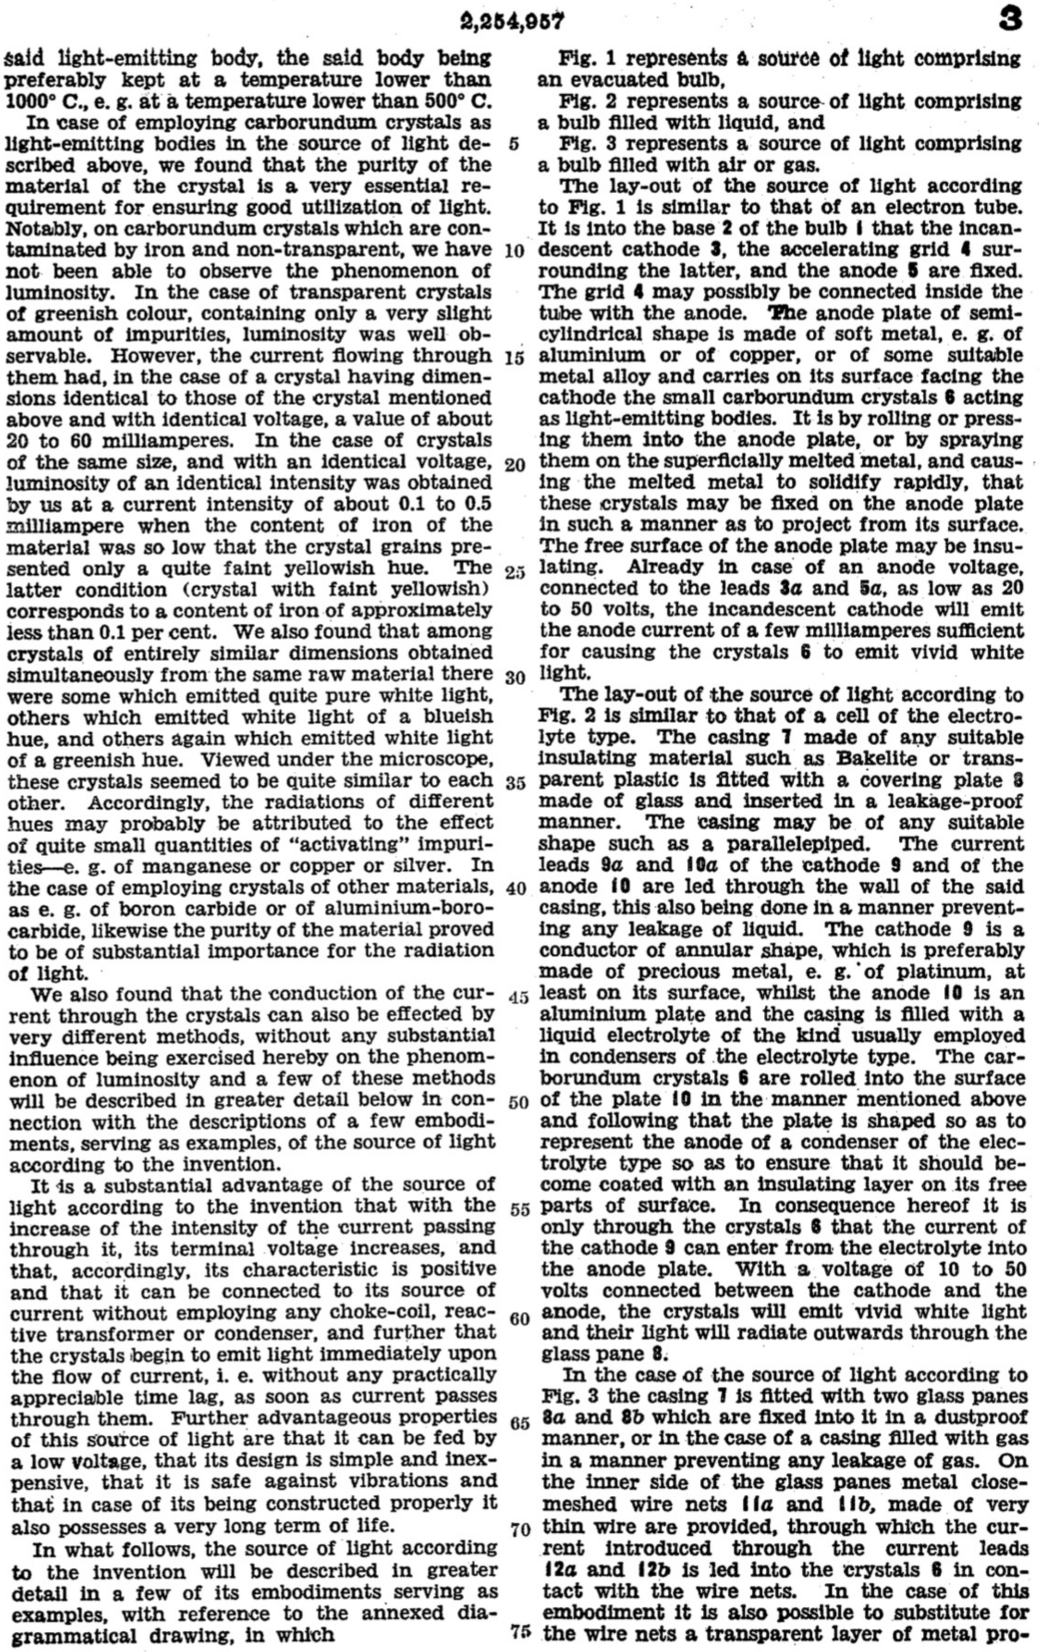
Finally, luminous phenomena were observed also in insulating liquids, if the latter were subjected to the action of a very intense electric field; thus, for instance, a mixture of diphenyl oxide and diphenyl placed between two electrodes situated at a distance of about one millimetre from each other has supplied light of sufficient intensity to enable a well-visible photographic picture to be taken of the phenomenon.

The source of light according to the invention is based on our discovery of the fact that the whole mass of certain transparent or at least semi-transparent electrically semi-conductive crystals becomes luminous when electric current passes through them, notwithstanding the fact that their temperature remains far below the temperature at which they would emit the thermal radiation corresponding to the light emitted by them. Thus, for instance, a transparent crystal of carborundum the dimensions of which are approximately between 0.1 and 1 millimetre and which is made from raw materials which are entirely pure, and particularly devoid of any contents of iron, will, when held fast between two electrodes, between which the voltage amounts in order of magnitude to 10 volts, in which case a current of about 0.1 milliampere passes through the crystal, become luminous so as to emit vivid white light, notably not only at the points of contact with the electrodes but in the whole mass of the crystal. This light can evidently not be considered to represent any thermal radiation, because it is only when employing a substantially higher current intensity and voltage that the crystal would begin to enter into red incandescence.

This new phenomenon can best be compared to fluorescence set up under the action of cathode rays, but with the substantial difference that it is not necessary to accelerate the electrons specially in a vacuum, the said electrons probably becoming accelerated in the crystal itself or in the closing layer existing on the surface of the crystal, and using their energy for generating the fluorescence of the crystal. The difference as compared to generation by means of cathode rays is, apart from the nature of the light-emitting substances, also substantial from the point of view that the voltage sufficient for generating the light is smaller by a whole order of magnitude than the one required in case of cathode rays. Notably, in the case of generation by means of cathode rays, a voltage of at least a few hundred, and possibly of several thousand volts is required, whereas the phenomenon constituting the basis of the invention presents itself already at voltages below 10 volts. Nor can the phenomenon be considered identical with the braking radiation described in what has preceded, because in braking radiation the radiation is developed by deceleration of electrons in a layer of less than 10^{-6} mm. thickness whereas in the present phenomenon the luminosity can be observed through the whole mass of the crystal. Accordingly what takes place probably is not that the energy of the electrons is being braked with concurrent emission of radiation, but that it causes the crystal to become fluorescent. Accordingly, if this assumption is correct, the difference between the radiation obtained in connection with the new phenomenon and that obtained in braking radiation is of a character similar to that of the difference between the fluorescent radiation generated by cathode rays produced with the aid of voltage of several thousand volts and the X-ray radiation generated by cathode rays of the same kind. Furthermore, the new phenomenon differs substantially also from the electro-luminescence set up in insulating liquids at high field intensities which has been described above, because this electro-luminescence is only set up at very high field intensities whereas a few volts are sufficient for producing the luminous phenomenon observed by us. This substantial difference is not only of quantitative but also of qualitative importance, seeing that the insulating substance contains no free electrons, and that it is therefore necessary to release them by the employment of high voltages, whereas in a conductor or semiconductor such electrons are available. We would, however, emphasize, that the correctness or incorrectness of the theoretical explanation attempted above of the new phenomenon discovered by us does not affect the substance of our invention, as it is a fact of experience that, in case the measures mentioned in the present specificatiion are strictly observed, it is possible to produce luminous radiation by means of the source of light according to the invention.

What is characteristic for the source of light according to the invention is therefore, according to what has been said above, that is light-emitting body is a transparent or semi-transparent, electrically conductive or semiconductive solid body radiating light under the direct effect of the current flowing through it. By direct effect we mean that, it is not in consequence of the thermal effect of the current flowing through it that the solid light-emitting body of the source of light according to the invention radiates light, the situation being thus contrary to the one existing with the incandescent bodies of the usual kinds of electric incandescent lamps, in which it is the thermal effect that represents the cause directly producing the radiation, and in which it is only indirectly, owing to the production of this thermal effect, that the electric current produces the luminous radiation, it being in fact immaterial for the light radiation of the incandescent body whether it is by means of electric current or by any other means that it is brought into a condition of incandescence. The solid light emitting body of the source of light according to the invention, on the other hand, is kept by the current flowing through it at a temperature lower than the one necessary for emitting the thermal radiation corresponding to the light radiated by the

Figure B.212: Zoltan Bay and György Szigeti filed patent applications on light emitting diodes (LEDs) in 1939.



said light-emitting body, the said body being preferably kept at a temperature lower than 1000° C., e. g. at a temperature lower than 500° C.

In case of employing carborundum crystals as light-emitting bodies in the source of light described above, we found that the purity of the material of the crystal is a very essential requirement for ensuring good utilization of light. Notably, on carborundum crystals which are contaminated by iron and non-transparent, we have not been able to observe the phenomenon of luminosity. In the case of transparent crystals of greenish colour, containing only a very slight amount of impurities, luminosity was well observable. However, the current flowing through them had, in the case of a crystal having dimensions identical to those of the crystal mentioned above and with identical voltage, a value of about 20 to 60 milliamperes. In the case of crystals of the same size, and with an identical voltage, luminosity of an identical intensity was obtained by us at a current intensity of about 0.1 to 0.5 milliampere when the content of iron of the material was so low that the crystal grains presented only a quite faint yellowish hue. The latter condition (crystal with faint yellowish) corresponds to a content of iron of approximately less than 0.1 per cent. We also found that among crystals of entirely similar dimensions obtained simultaneously from the same raw material there were some which emitted quite pure white light, others which emitted white light of a blueish hue, and others again which emitted white light of a greenish hue. Viewed under the microscope, these crystals seemed to be quite similar to each other. Accordingly, the radiations of different hues may probably be attributed to the effect of quite small quantities of "activating" impurities—e. g. of manganese or copper or silver. In the case of employing crystals of other materials, as e. g. of boron carbide or of aluminium-borocarbide, likewise the purity of the material proved to be of substantial importance for the radiation of light.

We also found that the conduction of the current through the crystals can also be effected by very different methods, without any substantial influence being exercised hereby on the phenomenon of luminosity and a few of these methods will be described in greater detail below in connection with the descriptions of a few embodiments, serving as examples, of the source of light according to the invention.

It is a substantial advantage of the source of light according to the invention that with the increase of the intensity of the current passing through it, its terminal voltage increases, and that, accordingly, its characteristic is positive and that it can be connected to its source of current without employing any choke-coil, reactive transformer or condenser, and further that the crystals begin to emit light immediately upon the flow of current, i. e. without any practically appreciable time lag, as soon as current passes through them. Further advantageous properties of this source of light are that it can be fed by a low voltage, that its design is simple and inexpensive, that it is safe against vibrations and that in case of its being constructed properly it also possesses a very long term of life.

In what follows, the source of light according to the invention will be described in greater detail in a few of its embodiments serving as examples, with reference to the annexed diagrammatical drawing, in which

Fig. 1 represents a source of light comprising an evacuated bulb,

Fig. 2 represents a source of light comprising a bulb filled with liquid, and

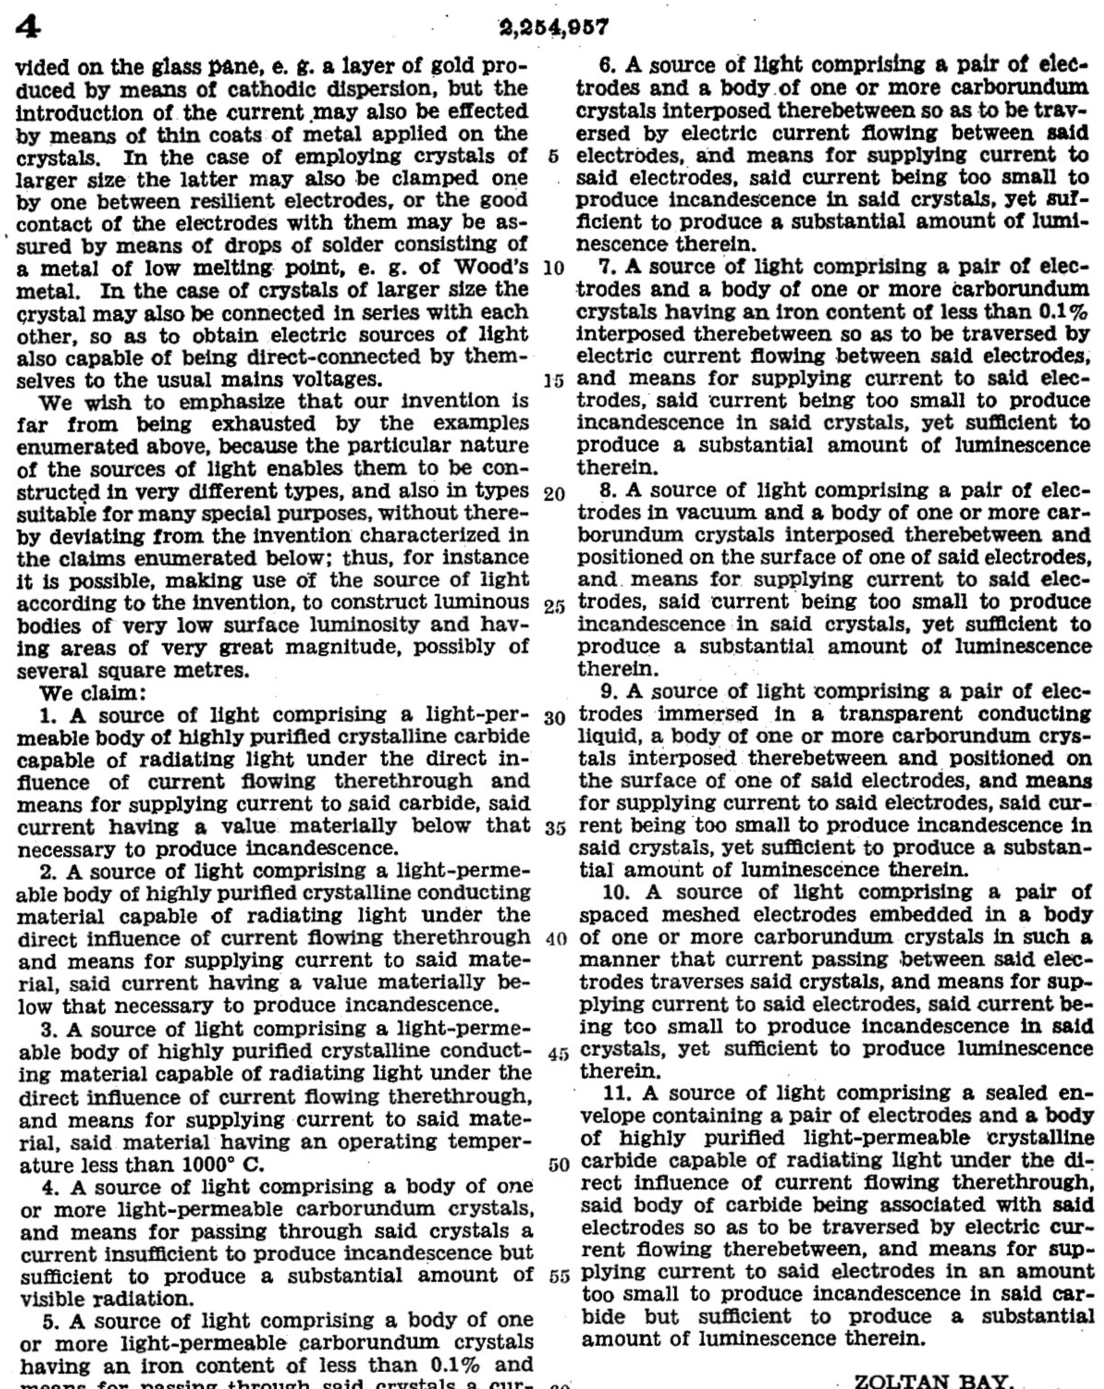
Fig. 3 represents a source of light comprising a bulb filled with air or gas.

The lay-out of the source of light according to Fig. 1 is similar to that of an electron tube. It is into the base 2 of the bulb 1 that the incandescent cathode 3, the accelerating grid 4 surrounding the latter, and the anode 5 are fixed. The grid 4 may possibly be connected inside the tube with the anode. The anode plate of semicylindrical shape is made of soft metal, e. g. of aluminium or of copper, or of some suitable metal alloy and carries on its surface facing the cathode the small carborundum crystals 6 acting as light-emitting bodies. It is by rolling or pressing them into the anode plate, or by spraying them on the superficially melted metal, and causing the melted metal to solidify rapidly, that these crystals may be fixed on the anode plate in such a manner as to project from its surface. The free surface of the anode plate may be insulating. Already in case of an anode voltage, connected to the leads 3*a* and 5*a*, as low as 20 to 50 volts, the incandescent cathode will emit the anode current of a few milliamperes sufficient for causing the crystals 6 to emit vivid white light.

The lay-out of the source of light according to Fig. 2 is similar to that of a cell of the electrolyte type. The casing 7 made of any suitable insulating material such as Bakelite or transparent plastic is fitted with a covering plate 8 made of glass and inserted in a leakage-proof manner. The casing may be of any suitable shape such as a parallelepiped. The current leads 9*a* and 10*a* of the cathode 9 and of the anode 10 are led through the wall of the said casing, this also being done in a manner preventing any leakage of liquid. The cathode 9 is a conductor of annular shape, which is preferably made of precious metal, e. g. of platinum, at least on its surface, whilst the anode 10 is an aluminium plate and the casing is filled with a liquid electrolyte of the kind usually employed in condensers of the electrolyte type. The carborundum crystals 6 are rolled into the surface of the plate 10 in the manner mentioned above and following that the plate is shaped so as to represent the anode of a condenser of the electrolyte type so as to ensure that it should become coated with an insulating layer on its free parts of surface. In consequence hereof it is only through the crystals 6 that the current of the cathode 9 can enter from the electrolyte into the anode plate. With a voltage of 10 to 50 volts connected between the cathode and the anode, the crystals will emit vivid white light and their light will radiate outwards through the glass pane 8.

In the case of the source of light according to Fig. 3 the casing 7 is fitted with two glass panes 8*a* and 8*b* which are fixed into it in a dustproof manner, or in the case of a casing filled with gas in a manner preventing any leakage of gas. On the inner side of the glass panes metal close-meshed wire nets 11*a* and 11*b*, made of very thin wire are provided, through which the current introduced through the current leads 12*a* and 12*b* is led into the crystals 6 in contact with the wire nets. In the case of this embodiment it is also possible to substitute for the wire nets a transparent layer of metal pro-

Figure B.213: Zoltan Bay and György Szigeti filed patent applications on light emitting diodes (LEDs) in 1939.



4 2,254,957

vided on the glass pane, e. g. a layer of gold produced by means of cathodic dispersion, but the introduction of the current may also be effected by means of thin coats of metal applied on the crystals. In the case of employing crystals of larger size the latter may also be clamped one by one between resilient electrodes, or the good contact of the electrodes with them may be assured by means of drops of solder consisting of a metal of low melting point, e. g. of Wood's metal. In the case of crystals of larger size the crystal may also be connected in series with each other, so as to obtain electric sources of light also capable of being direct-connected by themselves to the usual mains voltages.

We wish to emphasize that our invention is far from being exhausted by the examples enumerated above, because the particular nature of the sources of light enables them to be constructed in very different types, and also in types suitable for many special purposes, without thereby deviating from the invention characterized in the claims enumerated below; thus, for instance it is possible, making use of the source of light according to the invention, to construct luminous bodies of very low surface luminosity and having areas of very great magnitude, possibly of several square metres.

We claim:

1. A source of light comprising a light-permeable body of highly purified crystalline carbide capable of radiating light under the direct influence of current flowing therethrough and means for supplying current to said carbide, said current having a value materially below that necessary to produce incandescence.

2. A source of light comprising a light-permeable body of highly purified crystalline conducting material capable of radiating light under the direct influence of current flowing therethrough and means for supplying current to said material, said current having a value materially below that necessary to produce incandescence.

3. A source of light comprising a light-permeable body of highly purified crystalline conducting material capable of radiating light under the direct influence of current flowing therethrough, and means for supplying current to said material, said material having an operating temperature less than 1000° C.

4. A source of light comprising a body of one or more light-permeable carborundum crystals, and means for passing through said crystals a current insufficient to produce incandescence but sufficient to produce a substantial amount of visible radiation.

5. A source of light comprising a body of one or more light-permeable carborundum crystals having an iron content of less than 0.1% and means for passing through said crystals a current insufficient in magnitude to produce incandescence but sufficient to produce a substantial amount of visible radiation.

6. A source of light comprising a pair of electrodes and a body of one or more carborundum crystals interposed therebetween so as to be traversed by electric current flowing between said electrodes, and means for supplying current to said electrodes, said current being too small to produce incandescence in said crystals, yet sufficient to produce a substantial amount of luminescence therein.

7. A source of light comprising a pair of electrodes and a body of one or more carborundum crystals having an iron content of less than 0.1% interposed therebetween so as to be traversed by electric current flowing between said electrodes, and means for supplying current to said electrodes, said current being too small to produce incandescence in said crystals, yet sufficient to produce a substantial amount of luminescence therein.

8. A source of light comprising a pair of electrodes in vacuum and a body of one or more carborundum crystals interposed therebetween and positioned on the surface of one of said electrodes, and means for supplying current to said electrodes, said current being too small to produce incandescence in said crystals, yet sufficient to produce a substantial amount of luminescence therein.

9. A source of light comprising a pair of electrodes immersed in a transparent conducting liquid, a body of one or more carborundum crystals interposed therebetween and positioned on the surface of one of said electrodes, and means for supplying current to said electrodes, said current being too small to produce incandescence in said crystals, yet sufficient to produce a substantial amount of luminescence therein.

10. A source of light comprising a pair of spaced meshed electrodes embedded in a body of one or more carborundum crystals in such a manner that current passing between said electrodes traverses said crystals, and means for supplying current to said electrodes, said current being too small to produce incandescence in said crystals, yet sufficient to produce luminescence therein.

11. A source of light comprising a sealed envelope containing a pair of electrodes and a body of highly purified light-permeable crystalline carbide capable of radiating light under the direct influence of current flowing therethrough, said body of carbide being associated with said electrodes so as to be traversed by electric current flowing therebetween, and means for supplying current to said electrodes in an amount too small to produce incandescence in said carbide but sufficient to produce a substantial amount of luminescence therein.

PHOTON MODULATION IN SEMICONDUCTORS

Kurt Lehovec, Williamstown, Mass., assignor to the United States of America as represented by the Secretary of the Army

Application November 18, 1952, Serial No. 321,253

10 Claims. (Cl. 250—7)

This invention relates to novel processes for producing semiconductor translators and methods of controlling such translators to selectively absorb or emit light quanta in accordance with the rate of carrier injection in said semiconductor. More particularly, this invention relates to semiconductor materials which may be prepared to include selective impurity induced regional distortions. These distortions may be attributable to donor, acceptor, and activator inclusions, and as evidenced by lattice defects, stacking disorders, and structural anomalies in the basal lattice planes. Specifically, these regional distortions are selectively controlled so that the carrier charges injected into the semiconductor may cause energy changes therein to either absorb or emit light quanta.

It has long been known that certain materials generically grouped as phosphors would produce light emission in the form of fluorescence or phosphorescence when subjected to external stimuli, such as electronic bombardment or exposure to light.

It has also been long known that some semiconductor materials, such as silicon carbide crystals would luminesce if a potential was applied across it. The light emission was not caused by heating, and the presence underlying the process was unknown until recently. The intensity of the emission, however, was so slight as to be of no practical application, and the phenomenon had been relegated to a minor role as a mere physical curiosity.

Semiconductor materials, such as silicon and germanium, have also been noted to luminesce, but in view of the relative closeness of the absorption edge of the semiconductor and the frequency of the free emission, the luminescence was extremely weak because of absorption within the bulk of the material.

All of these prior art devices, while useful in certain limited applications, have failed to provide an effective and efficient translator for modulating intelligence with a high degree of fidelity. Accordingly, the present invention has for its primary purpose the utilization and proper control of two types of interrelated but distinct phenomena incident to semiconductor materials to modify the same for intelligence translators and modulators in a manner heretofore not considered possible. In general, the present invention depends for its novel result upon the selective injection of carriers into semiconductor materials which have been prepared in a certain manner. In one form, the translating characteristic of the invention is obtained upon absorption of radiant energy in the form of light; while in a second form, it is obtained upon the emission of radiant energy in the form of light; and in each instance the control of the radiant energy will depend upon the carrier current in the semiconductor body.

One object of the instant invention is to provide a semi-conductor photomodulator which may modulate a light beam passing through the semiconductor by selectively controllable absorption. A further object is to

2

provide a photo amplifying system of extremely minute size. Another object is the provision of a translating device composed of a semiconductor material which may emit light with high fidelity dependent upon an internal current flow composed of injected carriers. Other and distinct objects will become apparent from the description and claims which follow.

It is well known that the conductivity of an electronic semiconductor can be controlled by certain impurities or lattice defects, such as to be either n-type or p-type. Semiconductors have been made with regions of n-type conductivity and of p-type conductivity, bordering to each other with an interposed boundary or junction, commonly noted as an n-p-barrier between them. In some parts the electric charge or current is carried by electrons and is commonly denoted as n-type or excess conduction, while in other portions the electric current or charge is transmitted by holes (missing electrons) and is commonly denoted as p-type conduction. It is also known that if a voltage of proper polarity is applied across such a boundary, electrons may be driven from the n-part across the boundary and into the p-part and holes driven from the p-part across the boundary and into the n-part. This phenomenon corresponds to a simultaneous injection of minority carriers into each region tending to provide carrier balance or equilibrium.

If these electrons and holes are present simultaneously in particularly given locations within the semiconductor, the holes may function as traps for the electrons and both are annihilated, i. e. disappear as current or charge carriers producing a consequent change in the energy state of the semiconductor. Alternately if the semiconductor is prepared and operated in such manner that they do not recombine but are long lived and concentrated, the redistribution of elemental charges resulting also changes the energy state of the semiconductor. This change in energy state may be so controlled as to selectively absorb or emit light quanta according to the rate of carrier injection.

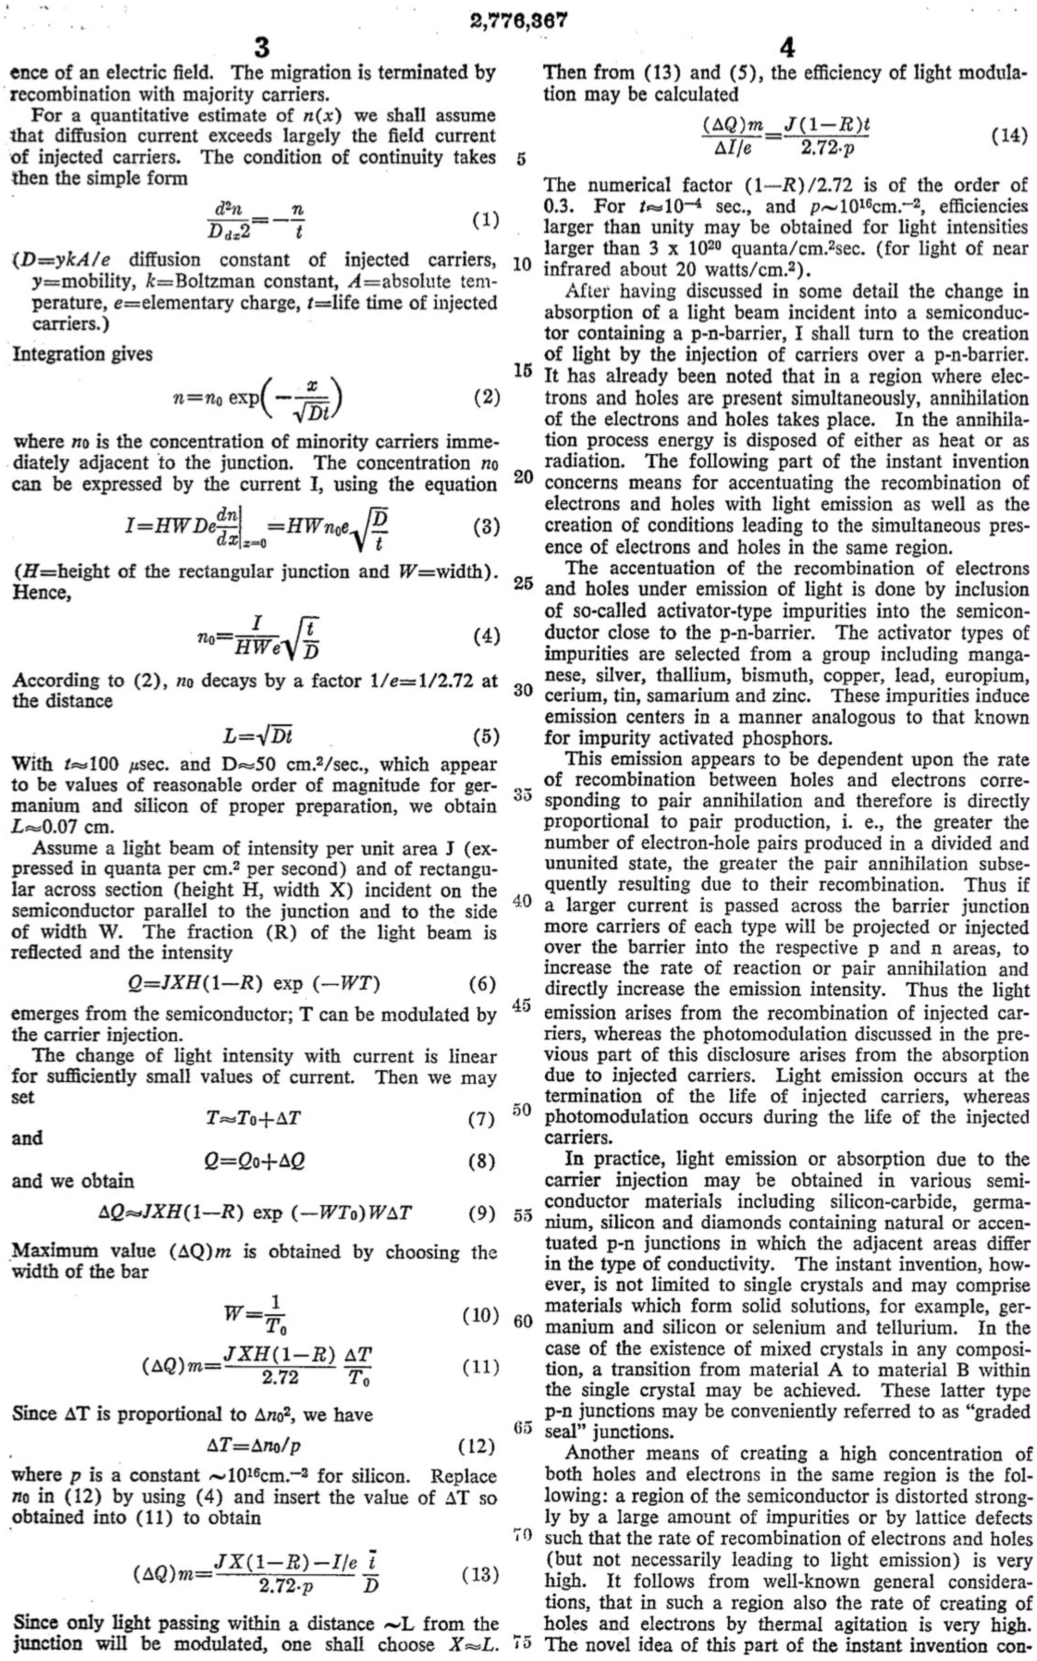
Photomodulation of an incident light beam results from the fact that the absorption characteristic of a semiconductor may be altered by the injection of charge carriers and is due to the absorption of the injected carriers proper or to an overall increase in absorption resulting from an increase in concentration of majority carriers brought about by the neutralization of the space charge of the injected carriers. The absorption of free carriers is responsible for the absorption in the region on the long wave side of the lattice absorption edge and has been correlated in this region with the concentration of carriers and particularly with respect to hole concentration (see 77 Phys. Rev. 727, 1950).

It is therefore possible to modify or modulate the absorption in a wave length region on the long wave side of the absorption edge by controlled carrier injection to bring about a corresponding regional change in the concentration of the carrier. This becomes particularly efficacious when the semiconductor is biased in the forward direction since such operation provides injection of carriers. Thus, an incident light beam of proper frequency and specified intensity may be directed into a semiconductor and therein selectively absorbed so that the beam emerging will be modulated according to the selective absorption induced in the semiconductor.

The theory of this phenomenon may be explained as follows:

The current in the forward direction over a p-n junction is due to injection of minority carriers (concentration $n(x)$). The minority carriers migrate into the bulk semiconductor by (a) diffusion and (b) under the influ-

Figure B.217: Kurt Lehovec worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs (possibly based on wartime work).



2,776,367

3

ence of an electric field. The migration is terminated by recombination with majority carriers.

For a quantitative estimate of $n(x)$ we shall assume that diffusion current exceeds largely the field current of injected carriers. The condition of continuity takes then the simple form

$$\frac{d^2n}{D_{dx}2}=-\frac{n}{t} \tag{1}$$

($D=ykA/e$ diffusion constant of injected carriers, y=mobility, k=Boltzman constant, A=absolute temperature, e=elementary charge, t=life time of injected carriers.)

Integration gives

$$n=n_0 \exp\left(-\frac{x}{\sqrt{Dt}}\right) \tag{2}$$

where n_0 is the concentration of minority carriers immediately adjacent to the junction. The concentration n_0 can be expressed by the current I, using the equation

$$I=HWDe\frac{dn}{dx}\bigg|_{x=0}=HWn_0e\sqrt{\frac{D}{t}} \tag{3}$$

(H=height of the rectangular junction and W=width). Hence,

$$n_0=\frac{I}{HWe}\sqrt{\frac{t}{D}} \tag{4}$$

According to (2), n_0 decays by a factor $1/e=1/2.72$ at the distance

$$L=\sqrt{Dt} \tag{5}$$

With $t\approx100$ μsec. and $D\approx50$ cm.^{2}/sec., which appear to be values of reasonable order of magnitude for germanium and silicon of proper preparation, we obtain $L\approx0.07$ cm.

Assume a light beam of intensity per unit area J (expressed in quanta per cm.^{2} per second) and of rectangular across section (height H, width X) incident on the semiconductor parallel to the junction and to the side of width W. The fraction (R) of the light beam is reflected and the intensity

$$Q=JXH(1-R)\ \exp\ (-WT) \tag{6}$$

emerges from the semiconductor; T can be modulated by the carrier injection.

The change of light intensity with current is linear for sufficiently small values of current. Then we may set

$$T\approx T_0+\Delta T \tag{7}$$

and

$$Q=Q_0+\Delta Q \tag{8}$$

and we obtain

$$\Delta Q\approx JXH(1-R)\ \exp\ (-WT_0)W\Delta T \tag{9}$$

Maximum value $(\Delta Q)m$ is obtained by choosing the width of the bar

$$W=\frac{1}{T_0} \tag{10}$$

$$(\Delta Q)m=\frac{JXH(1-R)}{2.72}\,\frac{\Delta T}{T_0} \tag{11}$$

Since ΔT is proportional to Δn_0^2, we have

$$\Delta T=\Delta n_0/p \tag{12}$$

where p is a constant $\sim10^{16}$cm.$^{-2}$ for silicon. Replace n_0 in (12) by using (4) and insert the value of ΔT so obtained into (11) to obtain

$$(\Delta Q)m=\frac{JX(1-R)-I/e}{2.72\cdot p}\,\frac{\bar{t}}{D} \tag{13}$$

Since only light passing within a distance $\sim$L from the junction will be modulated, one shall choose $X\approx L$.

4

Then from (13) and (5), the efficiency of light modulation may be calculated

$$\frac{(\Delta Q)m}{\Delta I/e}=\frac{J(1-R)t}{2.72\cdot p} \tag{14}$$

The numerical factor $(1-R)/2.72$ is of the order of 0.3. For $t\approx10^{-4}$ sec., and $p\sim10^{16}$cm.$^{-2}$, efficiencies larger than unity may be obtained for light intensities larger than 3 x 10^{20} quanta/cm.^{2}sec. (for light of near infrared about 20 watts/cm.^{2}).

After having discussed in some detail the change in absorption of a light beam incident into a semiconductor containing a p-n-barrier, I shall turn to the creation of light by the injection of carriers over a p-n-barrier. It has already been noted that in a region where electrons and holes are present simultaneously, annihilation of the electrons and holes takes place. In the annihilation process energy is disposed of either as heat or as radiation. The following part of the instant invention concerns means for accentuating the recombination of electrons and holes with light emission as well as the creation of conditions leading to the simultaneous presence of electrons and holes in the same region.

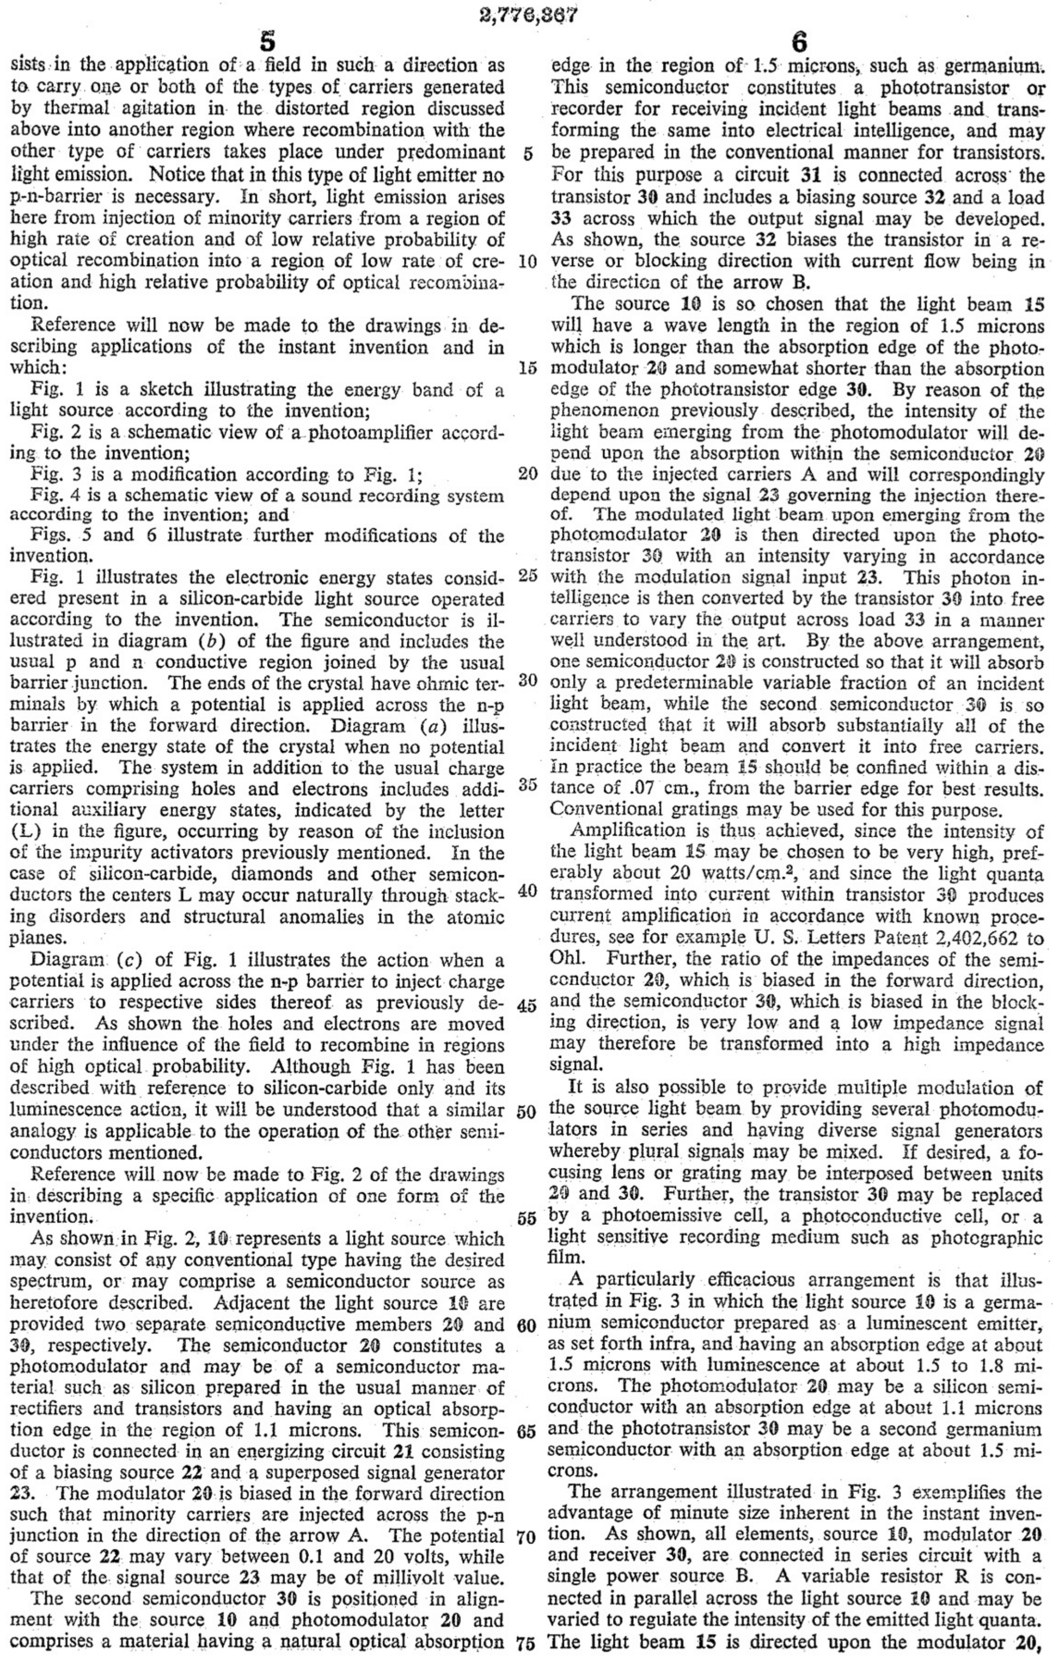
The accentuation of the recombination of electrons and holes under emission of light is done by inclusion of so-called activator-type impurities into the semiconductor close to the p-n-barrier. The activator types of impurities are selected from a group including manganese, silver, thallium, bismuth, copper, lead, europium, cerium, tin, samarium and zinc. These impurities induce emission centers in a manner analogous to that known for impurity activated phosphors.

This emission appears to be dependent upon the rate of recombination between holes and electrons corresponding to pair annihilation and therefore is directly proportional to pair production, i. e., the greater the number of electron-hole pairs produced in a divided and ununited state, the greater the pair annihilation subsequently resulting due to their recombination. Thus if a larger current is passed across the barrier junction more carriers of each type will be projected or injected over the barrier into the respective p and n areas, to increase the rate of reaction or pair annihilation and directly increase the emission intensity. Thus the light emission arises from the recombination of injected carriers, whereas the photomodulation discussed in the previous part of this disclosure arises from the absorption due to injected carriers. Light emission occurs at the termination of the life of injected carriers, whereas photomodulation occurs during the life of the injected carriers.

In practice, light emission or absorption due to the carrier injection may be obtained in various semiconductor materials including silicon-carbide, germanium, silicon and diamonds containing natural or accentuated p-n junctions in which the adjacent areas differ in the type of conductivity. The instant invention, however, is not limited to single crystals and may comprise materials which form solid solutions, for example, germanium and silicon or selenium and tellurium. In the case of the existence of mixed crystals in any composition, a transition from material A to material B within the single crystal may be achieved. These latter type p-n junctions may be conveniently referred to as "graded seal" junctions.

Another means of creating a high concentration of both holes and electrons in the same region is the following: a region of the semiconductor is distorted strongly by a large amount of impurities or by lattice defects such that the rate of recombination of electrons and holes (but not necessarily leading to light emission) is very high. It follows from well-known general considerations, that in such a region also the rate of creating of holes and electrons by thermal agitation is very high. The novel idea of this part of the instant invention con-

Figure B.218: Kurt Lehovec worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs (possibly based on wartime work).



sists in the application of a field in such a direction as to carry one or both of the types of carriers generated by thermal agitation in the distorted region discussed above into another region where recombination with the other type of carriers takes place under predominant light emission. Notice that in this type of light emitter no p-n-barrier is necessary. In short, light emission arises here from injection of minority carriers from a region of high rate of creation and of low relative probability of optical recombination into a region of low rate of creation and high relative probability of optical recombination.

Reference will now be made to the drawings in describing applications of the instant invention and in which:

Fig. 1 is a sketch illustrating the energy band of a light source according to the invention;

Fig. 2 is a schematic view of a photoamplifier according to the invention;

Fig. 3 is a modification according to Fig. 1;

Fig. 4 is a schematic view of a sound recording system according to the invention; and

Figs. 5 and 6 illustrate further modifications of the invention.

Fig. 1 illustrates the electronic energy states considered present in a silicon-carbide light source operated according to the invention. The semiconductor is illustrated in diagram (*b*) of the figure and includes the usual p and n conductive region joined by the usual barrier junction. The ends of the crystal have ohmic terminals by which a potential is applied across the n-p barrier in the forward direction. Diagram (*a*) illustrates the energy state of the crystal when no potential is applied. The system in addition to the usual charge carriers comprising holes and electrons includes additional auxiliary energy states, indicated by the letter (L) in the figure, occurring by reason of the inclusion of the impurity activators previously mentioned. In the case of silicon-carbide, diamonds and other semiconductors the centers L may occur naturally through stacking disorders and structural anomalies in the atomic planes.

Diagram (*c*) of Fig. 1 illustrates the action when a potential is applied across the n-p barrier to inject charge carriers to respective sides thereof as previously described. As shown the holes and electrons are moved under the influence of the field to recombine in regions of high optical probability. Although Fig. 1 has been described with reference to silicon-carbide only and its luminescence action, it will be understood that a similar analogy is applicable to the operation of the other semiconductors mentioned.

Reference will now be made to Fig. 2 of the drawings in describing a specific application of one form of the invention.

As shown in Fig. 2, **10** represents a light source which may consist of any conventional type having the desired spectrum, or may comprise a semiconductor source as heretofore described. Adjacent the light source **10** are provided two separate semiconductive members **20** and **30**, respectively. The semiconductor **20** constitutes a photomodulator and may be of a semiconductor material such as silicon prepared in the usual manner of rectifiers and transistors and having an optical absorption edge in the region of 1.1 microns. This semiconductor is connected in an energizing circuit **21** consisting of a biasing source **22** and a superposed signal generator **23**. The modulator **20** is biased in the forward direction such that minority carriers are injected across the p-n junction in the direction of the arrow A. The potential of source **22** may vary between 0.1 and 20 volts, while that of the signal source **23** may be of millivolt value.

The second semiconductor **30** is positioned in alignment with the source **10** and photomodulator **20** and comprises a material having a natural optical absorption edge in the region of 1.5 microns, such as germanium. This semiconductor constitutes a phototransistor or recorder for receiving incident light beams and transforming the same into electrical intelligence, and may be prepared in the conventional manner for transistors. For this purpose a circuit **31** is connected across the transistor **30** and includes a biasing source **32** and a load **33** across which the output signal may be developed. As shown, the source **32** biases the transistor in a reverse or blocking direction with current flow being in the direction of the arrow B.

The source **10** is so chosen that the light beam **15** will have a wave length in the region of 1.5 microns which is longer than the absorption edge of the photomodulator **20** and somewhat shorter than the absorption edge of the phototransistor edge **30**. By reason of the phenomenon previously described, the intensity of the light beam emerging from the photomodulator will depend upon the absorption within the semiconductor **20** due to the injected carriers A and will correspondingly depend upon the signal **23** governing the injection thereof. The modulated light beam upon emerging from the photomodulator **20** is then directed upon the phototransistor **30** with an intensity varying in accordance with the modulation signal input **23**. This photon intelligence is then converted by the transistor **30** into free carriers to vary the output across load **33** in a manner well understood in the art. By the above arrangement, one semiconductor **20** is constructed so that it will absorb only a predeterminable variable fraction of an incident light beam, while the second semiconductor **30** is so constructed that it will absorb substantially all of the incident light beam and convert it into free carriers. In practice the beam **15** should be confined within a distance of .07 cm., from the barrier edge for best results. Conventional gratings may be used for this purpose.

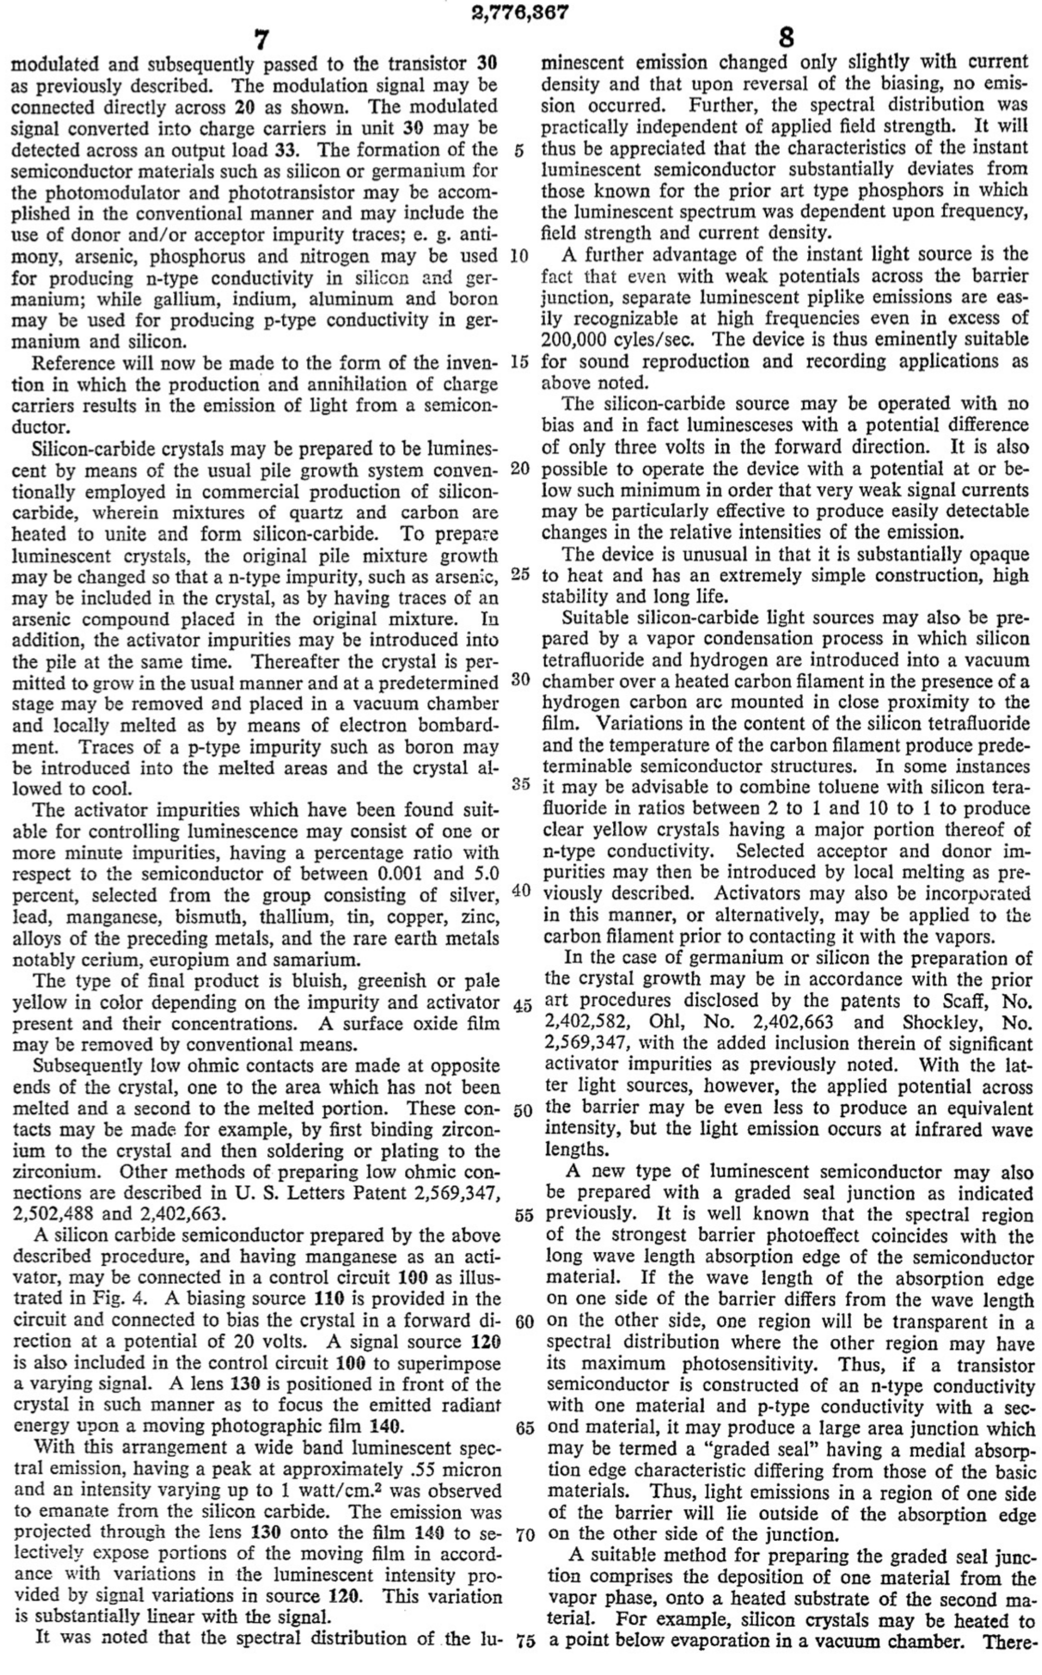
Amplification is thus achieved, since the intensity of the light beam **15** may be chosen to be very high, preferably about 20 watts/cm.^{2}, and since the light quanta transformed into current within transistor **30** produces current amplification in accordance with known procedures, see for example U. S. Letters Patent 2,402,662 to Ohl. Further, the ratio of the impedances of the semiconductor **20**, which is biased in the forward direction, and the semiconductor **30**, which is biased in the blocking direction, is very low and a low impedance signal may therefore be transformed into a high impedance signal.

It is also possible to provide multiple modulation of the source light beam by providing several photomodulators in series and having diverse signal generators whereby plural signals may be mixed. If desired, a focusing lens or grating may be interposed between units **20** and **30**. Further, the transistor **30** may be replaced by a photoemissive cell, a photoconductive cell, or a light sensitive recording medium such as photographic film.

A particularly efficacious arrangement is that illustrated in Fig. 3 in which the light source **10** is a germanium semiconductor prepared as a luminescent emitter, as set forth infra, and having an absorption edge at about 1.5 microns with luminescence at about 1.5 to 1.8 microns. The photomodulator **20** may be a silicon semiconductor with an absorption edge at about 1.1 microns and the phototransistor **30** may be a second germanium semiconductor with an absorption edge at about 1.5 microns.

The arrangement illustrated in Fig. 3 exemplifies the advantage of minute size inherent in the instant invention. As shown, all elements, source **10**, modulator **20** and receiver **30**, are connected in series circuit with a single power source B. A variable resistor R is connected in parallel across the light source **10** and may be varied to regulate the intensity of the emitted light quanta. The light beam **15** is directed upon the modulator **20**,

Figure B.219: Kurt Lehovec worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs (possibly based on wartime work).



2,776,367

7

modulated and subsequently passed to the transistor **30** as previously described. The modulation signal may be connected directly across **20** as shown. The modulated signal converted into charge carriers in unit **30** may be detected across an output load **33**. The formation of the semiconductor materials such as silicon or germanium for the photomodulator and phototransistor may be accomplished in the conventional manner and may include the use of donor and/or acceptor impurity traces; e. g. antimony, arsenic, phosphorus and nitrogen may be used for producing n-type conductivity in silicon and germanium; while gallium, indium, aluminum and boron may be used for producing p-type conductivity in germanium and silicon.

Reference will now be made to the form of the invention in which the production and annihilation of charge carriers results in the emission of light from a semiconductor.

Silicon-carbide crystals may be prepared to be luminescent by means of the usual pile growth system conventionally employed in commercial production of silicon-carbide, wherein mixtures of quartz and carbon are heated to unite and form silicon-carbide. To prepare luminescent crystals, the original pile mixture growth may be changed so that a n-type impurity, such as arsenic, may be included in the crystal, as by having traces of an arsenic compound placed in the original mixture. In addition, the activator impurities may be introduced into the pile at the same time. Thereafter the crystal is permitted to grow in the usual manner and at a predetermined stage may be removed and placed in a vacuum chamber and locally melted as by means of electron bombardment. Traces of a p-type impurity such as boron may be introduced into the melted areas and the crystal allowed to cool.

The activator impurities which have been found suitable for controlling luminescence may consist of one or more minute impurities, having a percentage ratio with respect to the semiconductor of between 0.001 and 5.0 percent, selected from the group consisting of silver, lead, manganese, bismuth, thallium, tin, copper, zinc, alloys of the preceding metals, and the rare earth metals notably cerium, europium and samarium.

The type of final product is bluish, greenish or pale yellow in color depending on the impurity and activator present and their concentrations. A surface oxide film may be removed by conventional means.

Subsequently low ohmic contacts are made at opposite ends of the crystal, one to the area which has not been melted and a second to the melted portion. These contacts may be made for example, by first binding zirconium to the crystal and then soldering or plating to the zirconium. Other methods of preparing low ohmic connections are described in U. S. Letters Patent 2,569,347, 2,502,488 and 2,402,663.

A silicon carbide semiconductor prepared by the above described procedure, and having manganese as an activator, may be connected in a control circuit **100** as illustrated in Fig. 4. A biasing source **110** is provided in the circuit and connected to bias the crystal in a forward direction at a potential of 20 volts. A signal source **120** is also included in the control circuit **100** to superimpose a varying signal. A lens **130** is positioned in front of the crystal in such manner as to focus the emitted radiant energy upon a moving photographic film **140**.

With this arrangement a wide band luminescent spectral emission, having a peak at approximately .55 micron and an intensity varying up to 1 watt/cm.^{2} was observed to emanate from the silicon carbide. The emission was projected through the lens **130** onto the film **140** to selectively expose portions of the moving film in accordance with variations in the luminescent intensity provided by signal variations in source **120**. This variation is substantially linear with the signal.

It was noted that the spectral distribution of the luminescent emission changed only slightly with current density and that upon reversal of the biasing, no emission occurred. Further, the spectral distribution was practically independent of applied field strength. It will thus be appreciated that the characteristics of the instant luminescent semiconductor substantially deviates from those known for the prior art type phosphors in which the luminescent spectrum was dependent upon frequency, field strength and current density.

8

A further advantage of the instant light source is the fact that even with weak potentials across the barrier junction, separate luminescent piplike emissions are easily recognizable at high frequencies even in excess of 200,000 cyles/sec. The device is thus eminently suitable for sound reproduction and recording applications as above noted.

The silicon-carbide source may be operated with no bias and in fact luminesceses with a potential difference of only three volts in the forward direction. It is also possible to operate the device with a potential at or below such minimum in order that very weak signal currents may be particularly effective to produce easily detectable changes in the relative intensities of the emission.

The device is unusual in that it is substantially opaque to heat and has an extremely simple construction, high stability and long life.

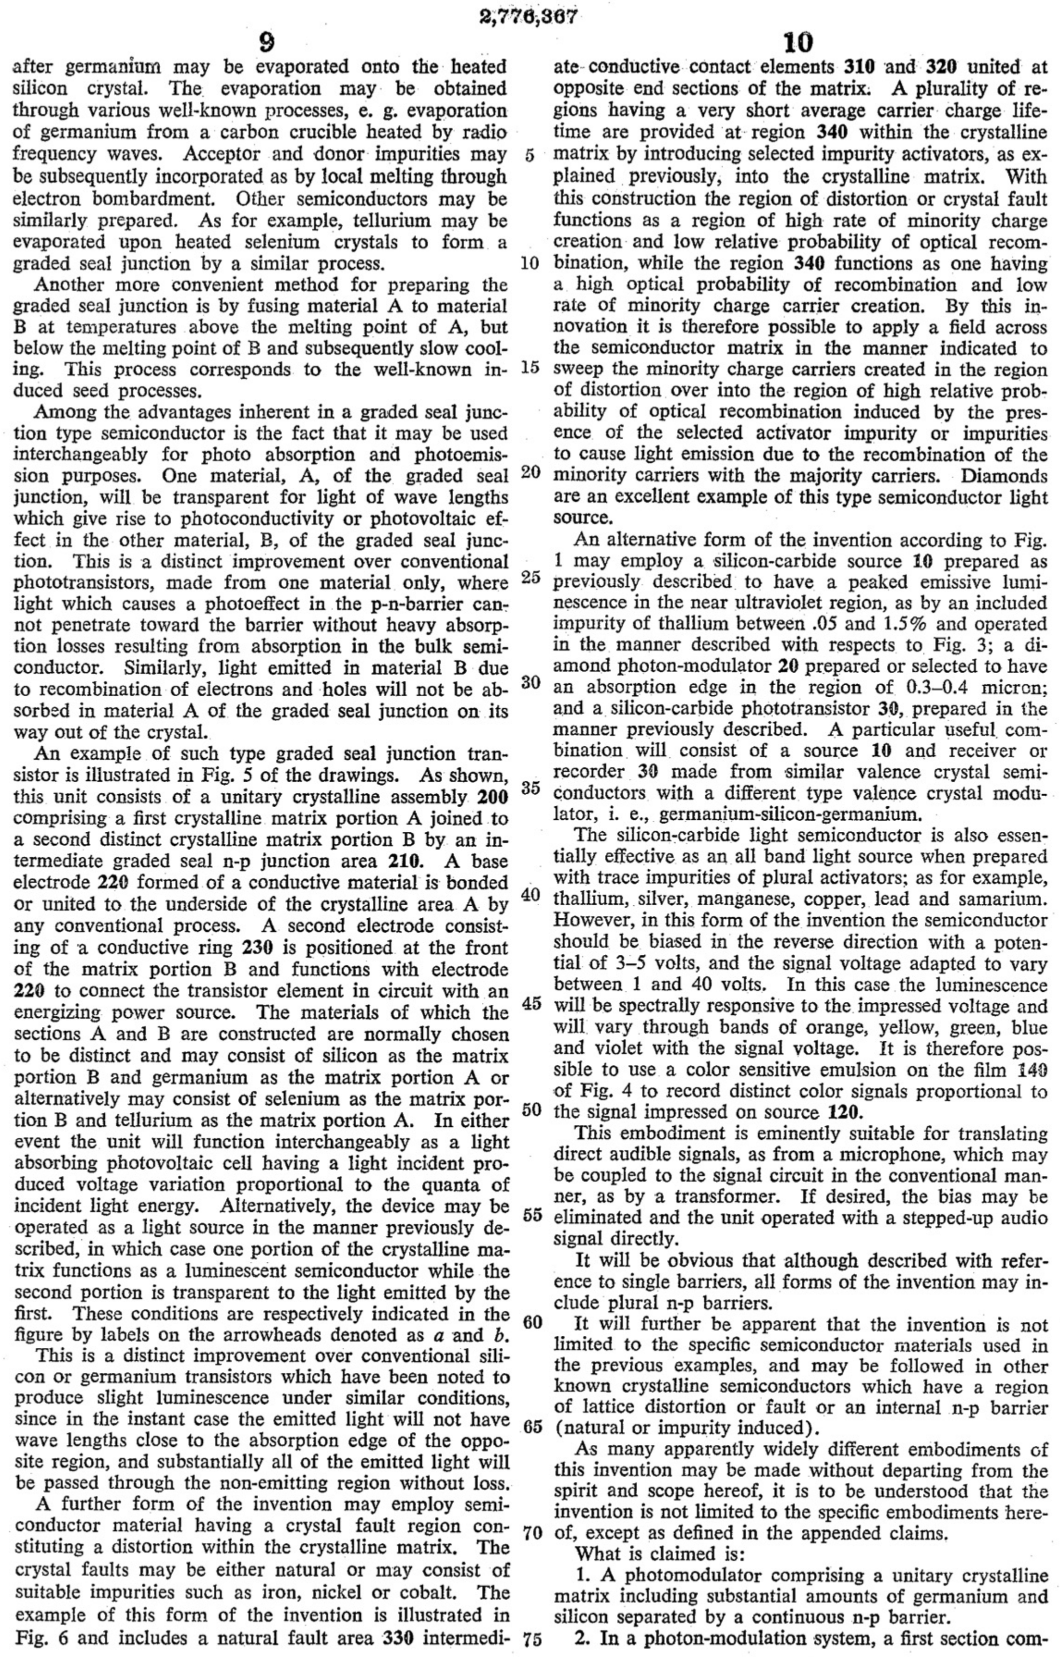
Suitable silicon-carbide light sources may also be prepared by a vapor condensation process in which silicon tetrafluoride and hydrogen are introduced into a vacuum chamber over a heated carbon filament in the presence of a hydrogen carbon arc mounted in close proximity to the film. Variations in the content of the silicon tetrafluoride and the temperature of the carbon filament produce predeterminable semiconductor structures. In some instances it may be advisable to combine toluene with silicon terafluoride in ratios between 2 to 1 and 10 to 1 to produce clear yellow crystals having a major portion thereof of n-type conductivity. Selected acceptor and donor impurities may then be introduced by local melting as previously described. Activators may also be incorporated in this manner, or alternatively, may be applied to the carbon filament prior to contacting it with the vapors.

In the case of germanium or silicon the preparation of the crystal growth may be in accordance with the prior art procedures disclosed by the patents to Scaff, No. 2,402,582, Ohl, No. 2,402,663 and Shockley, No. 2,569,347, with the added inclusion therein of significant activator impurities as previously noted. With the latter light sources, however, the applied potential across the barrier may be even less to produce an equivalent intensity, but the light emission occurs at infrared wave lengths.

A new type of luminescent semiconductor may also be prepared with a graded seal junction as indicated previously. It is well known that the spectral region of the strongest barrier photoeffect coincides with the long wave length absorption edge of the semiconductor material. If the wave length of the absorption edge on one side of the barrier differs from the wave length on the other side, one region will be transparent in a spectral distribution where the other region may have its maximum photosensitivity. Thus, if a transistor semiconductor is constructed of an n-type conductivity with one material and p-type conductivity with a second material, it may produce a large area junction which may be termed a "graded seal" having a medial absorption edge characteristic differing from those of the basic materials. Thus, light emissions in a region of one side of the barrier will lie outside of the absorption edge on the other side of the junction.

A suitable method for preparing the graded seal junction comprises the deposition of one material from the vapor phase, onto a heated substrate of the second material. For example, silicon crystals may be heated to a point below evaporation in a vacuum chamber. There-

Figure B.220: Kurt Lehovec worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs (possibly based on wartime work).



2,776,367

9

after germanium may be evaporated onto the heated silicon crystal. The evaporation may be obtained through various well-known processes, e. g. evaporation of germanium from a carbon crucible heated by radio frequency waves. Acceptor and donor impurities may be subsequently incorporated as by local melting through electron bombardment. Other semiconductors may be similarly prepared. As for example, tellurium may be evaporated upon heated selenium crystals to form a graded seal junction by a similar process.

Another more convenient method for preparing the graded seal junction is by fusing material A to material B at temperatures above the melting point of A, but below the melting point of B and subsequently slow cooling. This process corresponds to the well-known induced seed processes.

Among the advantages inherent in a graded seal junction type semiconductor is the fact that it may be used interchangeably for photo absorption and photoemission purposes. One material, A, of the graded seal junction, will be transparent for light of wave lengths which give rise to photoconductivity or photovoltaic effect in the other material, B, of the graded seal junction. This is a distinct improvement over conventional phototransistors, made from one material only, where light which causes a photoeffect in the p-n-barrier cannot penetrate toward the barrier without heavy absorption losses resulting from absorption in the bulk semiconductor. Similarly, light emitted in material B due to recombination of electrons and holes will not be absorbed in material A of the graded seal junction on its way out of the crystal.

An example of such type graded seal junction transistor is illustrated in Fig. 5 of the drawings. As shown, this unit consists of a unitary crystalline assembly **200** comprising a first crystalline matrix portion A joined to a second distinct crystalline matrix portion B by an intermediate graded seal n-p junction area **210**. A base electrode **220** formed of a conductive material is bonded or united to the underside of the crystalline area A by any conventional process. A second electrode consisting of a conductive ring **230** is positioned at the front of the matrix portion B and functions with electrode **220** to connect the transistor element in circuit with an energizing power source. The materials of which the sections A and B are constructed are normally chosen to be distinct and may consist of silicon as the matrix portion B and germanium as the matrix portion A or alternatively may consist of selenium as the matrix portion B and tellurium as the matrix portion A. In either event the unit will function interchangeably as a light absorbing photovoltaic cell having a light incident produced voltage variation proportional to the quanta of incident light energy. Alternatively, the device may be operated as a light source in the manner previously described, in which case one portion of the crystalline matrix functions as a luminescent semiconductor while the second portion is transparent to the light emitted by the first. These conditions are respectively indicated in the figure by labels on the arrowheads denoted as *a* and *b*.

This is a distinct improvement over conventional silicon or germanium transistors which have been noted to produce slight luminescence under similar conditions, since in the instant case the emitted light will not have wave lengths close to the absorption edge of the opposite region, and substantially all of the emitted light will be passed through the non-emitting region without loss.

A further form of the invention may employ semiconductor material having a crystal fault region constituting a distortion within the crystalline matrix. The crystal faults may be either natural or may consist of suitable impurities such as iron, nickel or cobalt. The example of this form of the invention is illustrated in Fig. 6 and includes a natural fault area **330** intermediate conductive contact elements **310** and **320** united at opposite end sections of the matrix. A plurality of regions having a very short average carrier charge lifetime are provided at region **340** within the crystalline matrix by introducing selected impurity activators, as explained previously, into the crystalline matrix. With this construction the region of distortion or crystal fault functions as a region of high rate of minority charge creation and low relative probability of optical recombination, while the region **340** functions as one having a high optical probability of recombination and low rate of minority charge carrier creation. By this innovation it is therefore possible to apply a field across the semiconductor matrix in the manner indicated to sweep the minority charge carriers created in the region of distortion over into the region of high relative probability of optical recombination induced by the presence of the selected activator impurity or impurities to cause light emission due to the recombination of the minority carriers with the majority carriers. Diamonds are an excellent example of this type semiconductor light source.

10

An alternative form of the invention according to Fig. 1 may employ a silicon-carbide source **10** prepared as previously described to have a peaked emissive luminescence in the near ultraviolet region, as by an included impurity of thallium between .05 and 1.5% and operated in the manner described with respects to Fig. 3; a diamond photon-modulator **20** prepared or selected to have an absorption edge in the region of 0.3–0.4 micron; and a silicon-carbide phototransistor **30**, prepared in the manner previously described. A particular useful combination will consist of a source **10** and receiver or recorder **30** made from similar valence crystal semiconductors with a different type valence crystal modulator, i. e., germanium-silicon-germanium.

The silicon-carbide light semiconductor is also essentially effective as an all band light source when prepared with trace impurities of plural activators; as for example, thallium, silver, manganese, copper, lead and samarium. However, in this form of the invention the semiconductor should be biased in the reverse direction with a potential of 3–5 volts, and the signal voltage adapted to vary between 1 and 40 volts. In this case the luminescence will be spectrally responsive to the impressed voltage and will vary through bands of orange, yellow, green, blue and violet with the signal voltage. It is therefore possible to use a color sensitive emulsion on the film **140** of Fig. 4 to record distinct color signals proportional to the signal impressed on source **120**.

This embodiment is eminently suitable for translating direct audible signals, as from a microphone, which may be coupled to the signal circuit in the conventional manner, as by a transformer. If desired, the bias may be eliminated and the unit operated with a stepped-up audio signal directly.

It will be obvious that although described with reference to single barriers, all forms of the invention may include plural n-p barriers.

It will further be apparent that the invention is not limited to the specific semiconductor materials used in the previous examples, and may be followed in other known crystalline semiconductors which have a region of lattice distortion or fault or an internal n-p barrier (natural or impurity induced).

As many apparently widely different embodiments of this invention may be made without departing from the spirit and scope hereof, it is to be understood that the invention is not limited to the specific embodiments hereof, except as defined in the appended claims.

What is claimed is:

1. A photomodulator comprising a unitary crystalline matrix including substantial amounts of germanium and silicon separated by a continuous n-p barrier.

2. In a photon-modulation system, a first section com-

Figure B.221: Kurt Lehovec worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs (possibly based on wartime work).

11

prising an emissive source of light quanta, a second section operatively connected with said first section and including a structure for modulating said light quanta, said sections comprising a semiconductor translator having internal n-p barriers, one of said sections comprising a silicon-germanium semiconductor, and means for applying a unidirectional biasing field across said n-p barriers.

3. A unitary crystalline semiconductor light source, comprising two different semiconductor materials integrally connected by a graded junction, one semiconductor being n-type and the other p-type, and means for applying a potential across the unitary semiconductor in the forward direction of the n-p junction, said materials being germanium and silicon.

4. A unitary crystalline phototransistor comprising two different semiconductor materials integrally connected by a graded junction, one semiconductor being n-type, and the other p-type, and means for applying a potential across the unitary semiconductor in the blocking direction, said materials being germanium and silicon.

5. A unitary crystalline photovoltaic cell comprising two different semiconductor materials integrally connected by a graded junction, one semiconductor being n-type, the other p-type, an electrode on the p-type semiconductor, a second electrode on the n-type semiconductor, and means for applying a potential across the unitary semiconductor, said materials being germanium and silicon.

6. A photon transducer comprising a unitary crystalline matrix including substantial amounts of germanium and silicon separated by a continuous n-p barrier.

7. In a photon-modulation system, a first section comprising an emissive source of light quanta, a second section operatively connected with said first section and including structure for modulating said source light quanta, said sections comprising semiconductor translators having internal n-p barriers, means for applying a unidirectional biasing field across said n-p barriers, at least one of said translators comprising two materials having different long wave light absorption edges, said materials respectively containing n and p inducting impurities, said barrier being an internal n-p graded junction between said materials, and wherein said materials are germanium and silicon.

8. A unitary crystalline semiconductor light source, comprising two different semiconductor materials integrally connected by a graded junction, one semiconductor

12

being n-type, the other p-type, and means for applying a potential across the unitary semiconductor in the forward direction of the n-p junction, said materials respectively having different long wave light absorption edges, said materials respectively containing n and p inducing impurities, and wherein said materials are germanium and silicon.

9. A unitary crystalline phototransistor comprising two different semiconductor materials integrally connected by a graded junction, one semiconductor being n-type, the other p-type, means for applying a potential across the unitary semiconductor in the blocking direction, said materials respectively having different long wave light absorption edges, said materials respectively containing n and p inducing impurities, and wherein said materials are germanium and silicon.

10. A unitary crystalline photovoltaic cell comprising two different semiconductor materials integrally connected by a graded junction, one semiconductor being n-type, the other p-type, an electrode on the p-type semiconductor, a second electrode on the n-type semiconductor, means for applying a potential across the unitary semiconductor, said materials respectively having different long wave light absorption edges, said materials respectively containing n and p inducing impurities, and wherein said materials are germanium and silicon.

DOUBLE MODULATOR UTILIZING PHOTO EMISSIVE MATERIAL

Kurt Lehovec, Williamstown, Mass., assignor to the United States of America as represented by the Secretary of the Army

Application November 18, 1952, Serial No. 321,254

3 Claims. (Cl. 250—210)

This invention relates to semiconductor translators and more particularly to a new type of luminescent semiconductor. Specifically, the invention relates to novel multiplex signal circuits employing semiconductor photon modulation in a manner not heretofore considered possible.

Certain types of photo-emissive and photo-sensitive electrical translators have long been known and used in the art for numerous applications. Examples of these prior art devices include the phosphors such as alkali halides, zinc sulphide and zinc silicate, as both luminescent and photo-sensitive translators. Other examples are the common photo-emissive cells (caesium, etc.), either vacuum or gas-type, photo-voltaic cells such as copper-oxide and photo-conductive cells such as selenium. These devices, while suitable for certain limited applications, are all subject to deficiencies as is well known in the art. In particular, there has been a long-felt need in this field for a simple, stable and rugged type of versatile light source which could supplant the present fluorescent and phosphorescent phosphor sources with their narrowly limited applications, as well as prototype lamps.

This disadvantage has been terminated by the discovery of new semiconductor photon modulators as set forth in my concurrent application, Serial No. 321,253, filed on even date with this application, and entitled "Photon Modulation in Semiconductors" (now Patent No. 2,776,367). The instant invention is concerned with the application of such devices in suitable networks to provide uniquely simple intelligence integration and differentiation systems.

As described more fully in said concurrent application, the new modulators comprise a semiconductive crystalline matrix having an integral n-p barrier and included substitutional and/or interstitial impurities, which in its broadest sense may consist of structural faults or anomalies in the atomic order, and which render the unit either luminescent under certain electrical stimulae or photon absorbent, or both.

The class of semiconductors suitable include silicon, germanium, silicon-carbide and natural and synthetic diamonds, as well as graded seal junction matrices such as germanium-silicon and tellurium-selenium. In most instances, the semiconductors include, in addition to the usual donor and acceptor impurities, at least one additional luminescense enhancing impurity selected from the group comprising zinc, copper, lead, tin, silver, manganese, thallium, bismuth, cerium, europium and samarium. However, certain semiconductors may fluoresce without need of deliberately added activators, as set forth more fully in said concurrent application.

When a minimum potential difference, exceeding 3 volts for silicon-carbide, is applied across such semiconductor in a forward direction, it luminesces with an intensity proportional to the current passed. This is attributable to the injection of charge carriers from one side of the n-p barrier to the other and a subsequent optical recombination. The theory explaining this operation is fully set forth in said concurrent application.

2

Another type of a semiconductor light source modulated by an external electric signal and more fully described in said concurrent application consists in passing an external source light beam through a region adjacent to a p-n barrier of a semiconductor, which semiconductor is biased in the forward direction, so that the electrons and holes injected over the p-n barrier modulate the absorption undergone by the light beam in passing through the semiconductor.

The instant invention has for its primary purpose the application of such new light sources in combination with light-sensitive recorders or receivers in such a manner as to permit integration or differentiation between diverse electrical signals.

In one preferred form of the invention a semiconductor light source is arranged to cooperate with a light-sensitive cell in an electrical network whereby the output of the network may represent either, the summation of two values represented by signals in the network, a selected one of such input signals, or a heterodyning signal generator.

A second form of the invention relates to a frequency analyzer.

Another form of the invention is directed to providing novel circuit components for analogue computers.

A still further form of the invention is directed to a system for high fidelity amplification.

The invention may be described broadly as comprising a semiconductor light source and a light-sensitive (photo-conductive) receiver. The latter may be either a semiconductor of the type set forth in said concurrent application or a conventional photo-emissive or photo-conductive cell. The source or emitter and receiver or collector cell, as they will be hereafter designated, are arranged to cooperate together with respect to an electrical network, which in each instance, may be pre-controlled or set to provide unique results.

Reference will now be made to the drawings in more fully describing certain specific embodiments of the invention, and in which:

Fig. 1 illustrates a semiconductor light source according to the instant invention;

Fig. 2 is a graph illustrating the relation of various phenomena in the semiconductor of Fig. 1;

Figs. 3 and 4 are characteristic graphs of conventional photo-emissive cells and a photo-conductive cell;

Fig. 5 is an illustration of one form of the invention employing a balanced network;

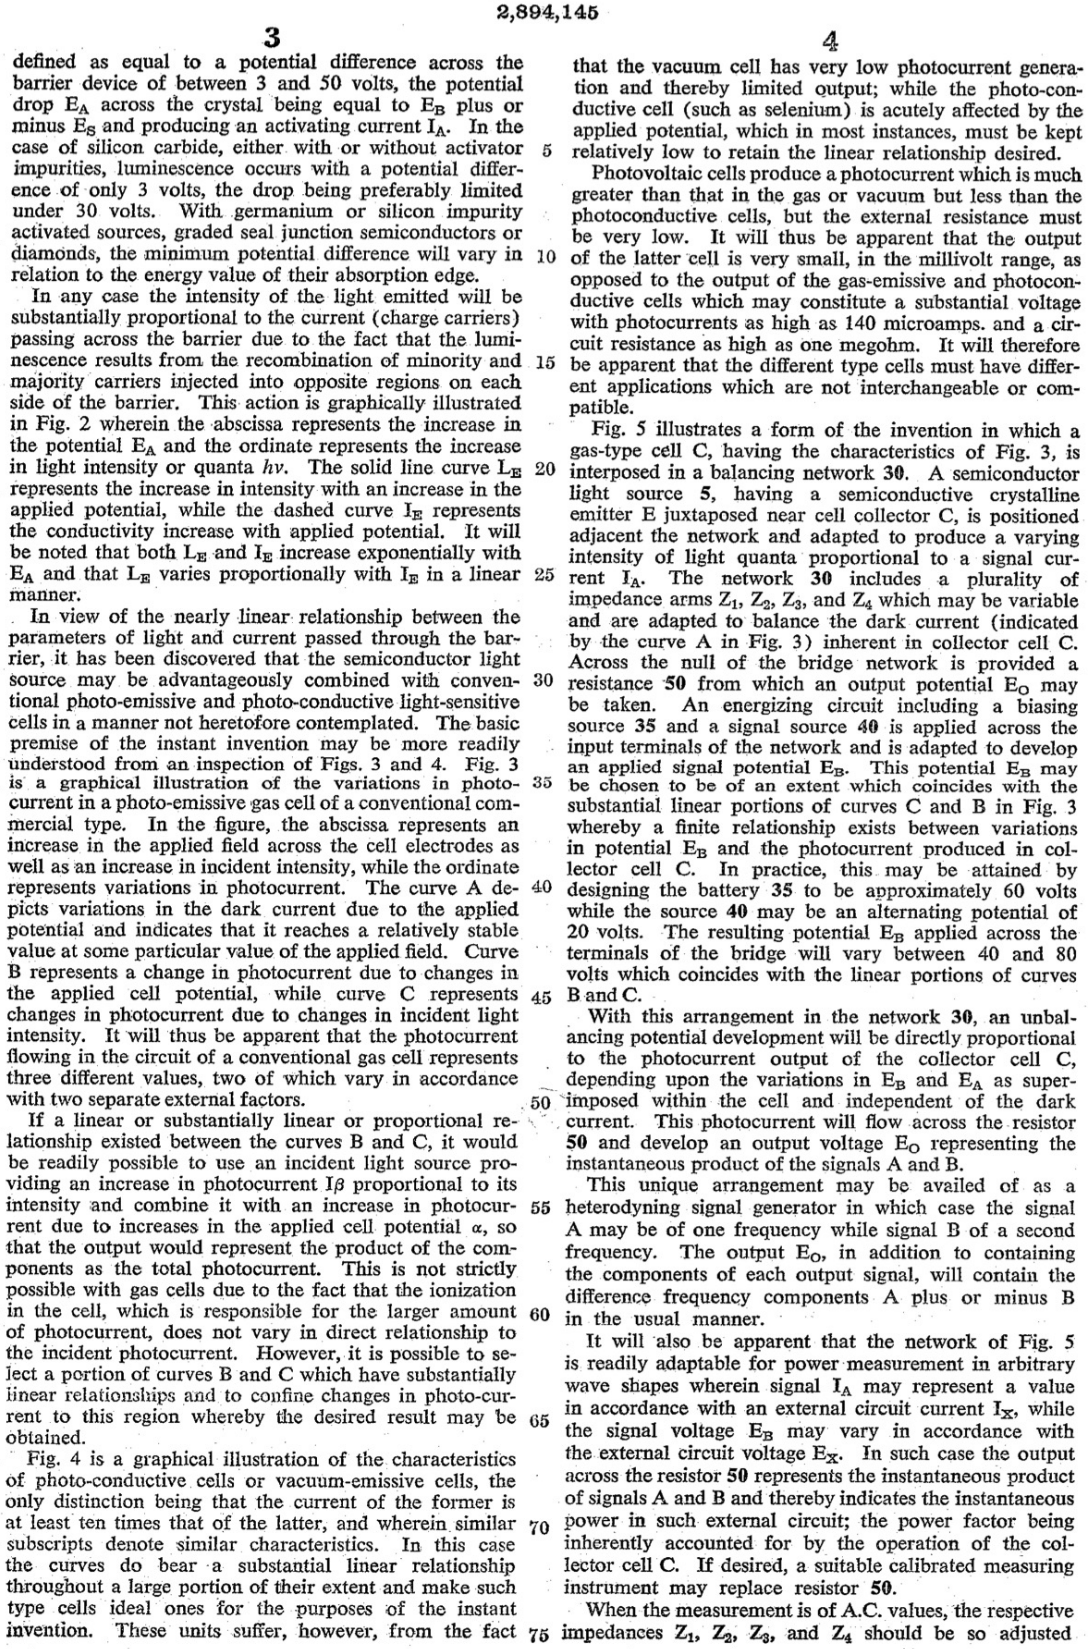
Fig. 6 is a graphical analysis of the action of circuit of Fig. 5;

Figs. 7, 8 and 9 illustrate the application of the invention to particular component arrangements for analogue computers; and

Fig. 10 illustrates a further modification of the invention.

As illustrated in Fig. 1, the semiconductor light sources according to the invention comprise a semiconductor crystalline matrix **10** having p- and n-type conductivity regions juxtaposed on opposite sides of a central high resistance barrier layer. As shown, the matrix **10** includes only one such barrier, but it will be readily understood that the invention is applicable to matrices employing a plurality of such barriers. The energizing circuit **15** is connected via low ohmic contacts to the respective ends of the matrix **10** and includes a bias source **20** (E_B) and a signal source **25** (E_S). The values assigned to the bias **20** and the signal **25** will differ according to the particular semiconductor utilized, as set forth more fully in said concurrent application, but may be broadly

Figure B.226: Kurt Lehovec worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs (possibly based on wartime work).



2,894,145

3

defined as equal to a potential difference across the barrier device of between 3 and 50 volts, the potential drop E_A across the crystal being equal to E_B plus or minus E_S and producing an activating current I_A. In the case of silicon carbide, either with or without activator impurities, luminescence occurs with a potential difference of only 3 volts, the drop being preferably limited under 30 volts. With germanium or silicon impurity activated sources, graded seal junction semiconductors or diamonds, the minimum potential difference will vary in relation to the energy value of their absorption edge.

In any case the intensity of the light emitted will be substantially proportional to the current (charge carriers) passing across the barrier due to the fact that the luminescence results from the recombination of minority and majority carriers injected into opposite regions on each side of the barrier. This action is graphically illustrated in Fig. 2 wherein the abscissa represents the increase in the potential E_A and the ordinate represents the increase in light intensity or quanta $h\nu$. The solid line curve L_E represents the increase in intensity with an increase in the applied potential, while the dashed curve I_E represents the conductivity increase with applied potential. It will be noted that both L_E and I_E increase exponentially with E_A and that L_E varies proportionally with I_E in a linear manner.

In view of the nearly linear relationship between the parameters of light and current passed through the barrier, it has been discovered that the semiconductor light source may be advantageously combined with conventional photo-emissive and photo-conductive light-sensitive cells in a manner not heretofore contemplated. The basic premise of the instant invention may be more readily understood from an inspection of Figs. 3 and 4. Fig. 3 is a graphical illustration of the variations in photocurrent in a photo-emissive gas cell of a conventional commercial type. In the figure, the abscissa represents an increase in the applied field across the cell electrodes as well as an increase in incident intensity, while the ordinate represents variations in photocurrent. The curve A depicts variations in the dark current due to the applied potential and indicates that it reaches a relatively stable value at some particular value of the applied field. Curve B represents a change in photocurrent due to changes in the applied cell potential, while curve C represents changes in photocurrent due to changes in incident light intensity. It will thus be apparent that the photocurrent flowing in the circuit of a conventional gas cell represents three different values, two of which vary in accordance with two separate external factors.

If a linear or substantially linear or proportional relationship existed between the curves B and C, it would be readily possible to use an incident light source providing an increase in photocurrent $I\beta$ proportional to its intensity and combine it with an increase in photocurrent due to increases in the applied cell potential α, so that the output would represent the product of the components as the total photocurrent. This is not strictly possible with gas cells due to the fact that the ionization in the cell, which is responsible for the larger amount of photocurrent, does not vary in direct relationship to the incident photocurrent. However, it is possible to select a portion of curves B and C which have substantially linear relationships and to confine changes in photo-current to this region whereby the desired result may be obtained.

Fig. 4 is a graphical illustration of the characteristics of photo-conductive cells or vacuum-emissive cells, the only distinction being that the current of the former is at least ten times that of the latter, and wherein similar subscripts denote similar characteristics. In this case the curves do bear a substantial linear relationship throughout a large portion of their extent and make such type cells ideal ones for the purposes of the instant invention. These units suffer, however, from the fact that the vacuum cell has very low photocurrent generation and thereby limited output; while the photo-conductive cell (such as selenium) is acutely affected by the applied potential, which in most instances, must be kept relatively low to retain the linear relationship desired.

4

Photovoltaic cells produce a photocurrent which is much greater than that in the gas or vacuum but less than the photoconductive cells, but the external resistance must be very low. It will thus be apparent that the output of the latter cell is very small, in the millivolt range, as opposed to the output of the gas-emissive and photoconductive cells which may constitute a substantial voltage with photocurrents as high as 140 microamps. and a circuit resistance as high as one megohm. It will therefore be apparent that the different type cells must have different applications which are not interchangeable or compatible.

Fig. 5 illustrates a form of the invention in which a gas-type cell C, having the characteristics of Fig. 3, is interposed in a balancing network **30**. A semiconductor light source **5**, having a semiconductive crystalline emitter E juxtaposed near cell collector C, is positioned adjacent the network and adapted to produce a varying intensity of light quanta proportional to a signal current I_A. The network **30** includes a plurality of impedance arms Z_1, Z_2, Z_3, and Z_4 which may be variable and are adapted to balance the dark current (indicated by the curve A in Fig. 3) inherent in collector cell C. Across the null of the bridge network is provided a resistance **50** from which an output potential E_O may be taken. An energizing circuit including a biasing source **35** and a signal source **40** is applied across the input terminals of the network and is adapted to develop an applied signal potential E_B. This potential E_B may be chosen to be of an extent which coincides with the substantial linear portions of curves C and B in Fig. 3 whereby a finite relationship exists between variations in potential E_B and the photocurrent produced in collector cell C. In practice, this may be attained by designing the battery **35** to be approximately 60 volts while the source **40** may be an alternating potential of 20 volts. The resulting potential E_B applied across the terminals of the bridge will vary between 40 and 80 volts which coincides with the linear portions of curves B and C.

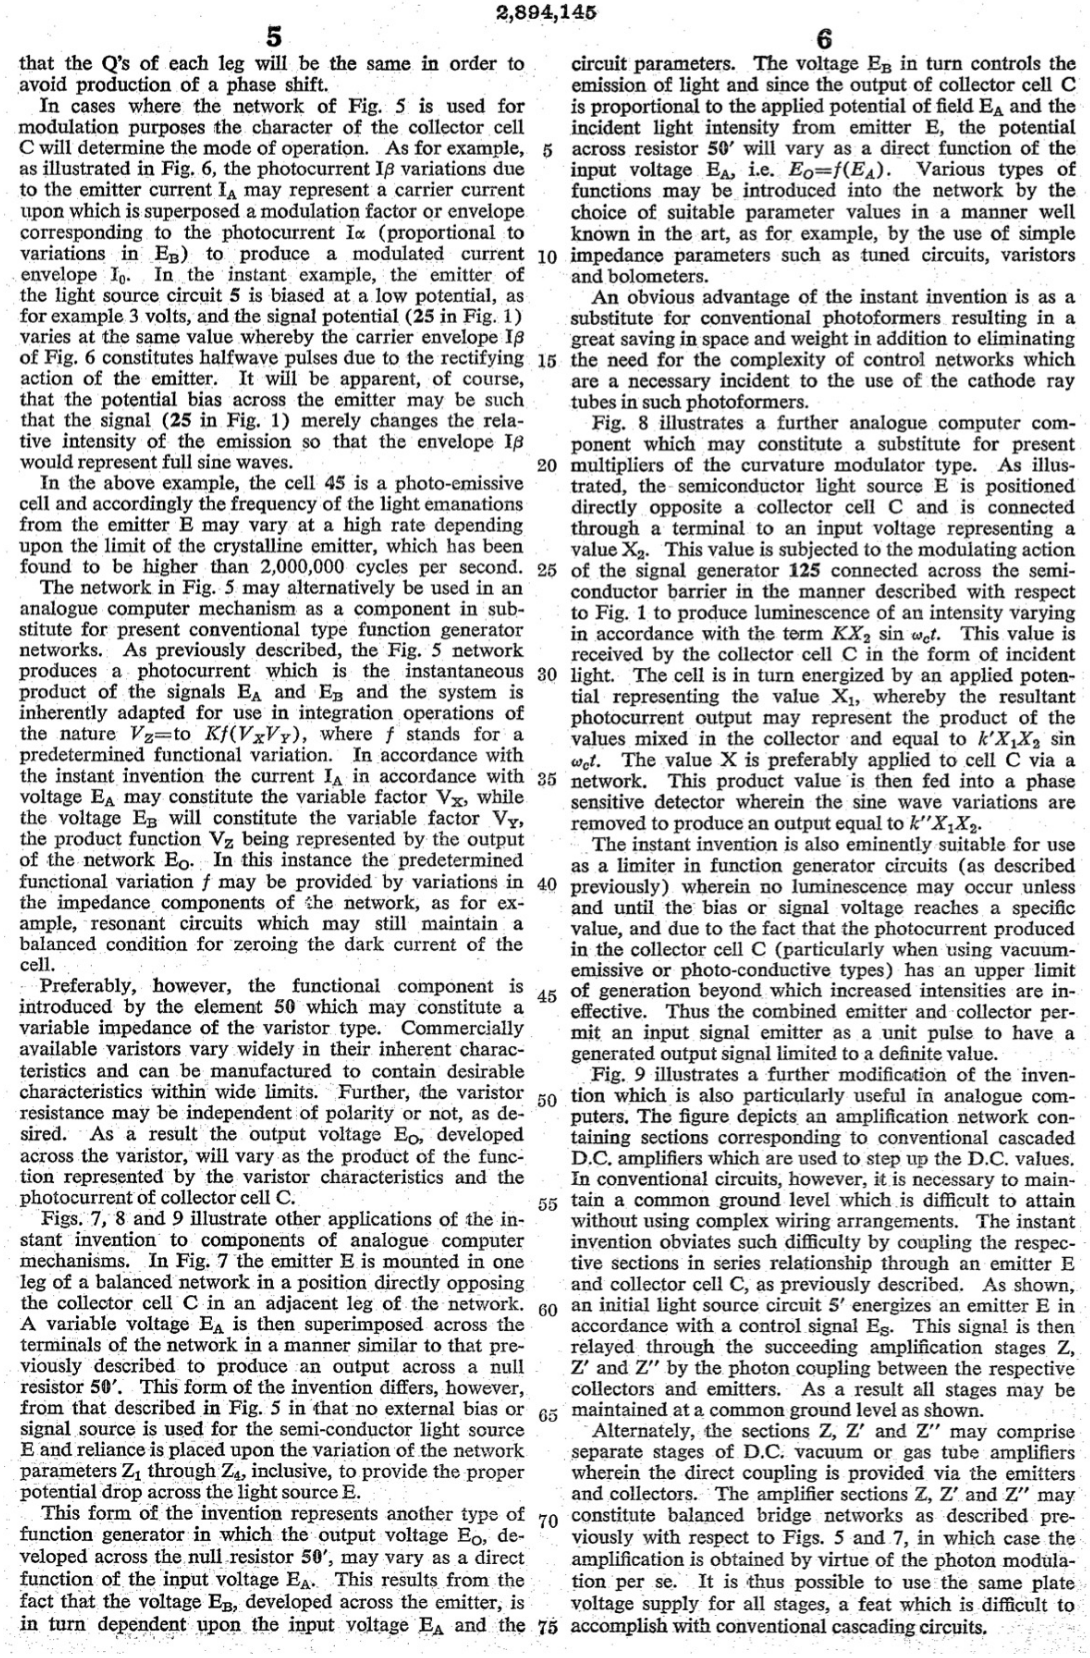
With this arrangement in the network **30**, an unbalancing potential development will be directly proportional to the photocurrent output of the collector cell C, depending upon the variations in E_B and E_A as superimposed within the cell and independent of the dark current. This photocurrent will flow across the resistor **50** and develop an output voltage E_O representing the instantaneous product of the signals A and B.

This unique arrangement may be availed of as a heterodyning signal generator in which case the signal A may be of one frequency while signal B of a second frequency. The output E_O, in addition to containing the components of each output signal, will contain the difference frequency components A plus or minus B in the usual manner.

It will also be apparent that the network of Fig. 5 is readily adaptable for power measurement in arbitrary wave shapes wherein signal I_A may represent a value in accordance with an external circuit current I_X, while the signal voltage E_B may vary in accordance with the external circuit voltage E_X. In such case the output across the resistor **50** represents the instantaneous product of signals A and B and thereby indicates the instantaneous power in such external circuit; the power factor being inherently accounted for by the operation of the collector cell C. If desired, a suitable calibrated measuring instrument may replace resistor **50**.

When the measurement is of A.C. values, the respective impedances Z_1, Z_2, Z_3, and Z_4 should be so adjusted

Figure B.227: Kurt Lehovec worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs (possibly based on wartime work).



that the Q's of each leg will be the same in order to avoid production of a phase shift.

In cases where the network of Fig. 5 is used for modulation purposes the character of the collector cell C will determine the mode of operation. As for example, as illustrated in Fig. 6, the photocurrent $I\beta$ variations due to the emitter current I_A may represent a carrier current upon which is superposed a modulation factor or envelope corresponding to the photocurrent $I\alpha$ (proportional to variations in E_B) to produce a modulated current envelope I_0. In the instant example, the emitter of the light source circuit **5** is biased at a low potential, as for example 3 volts, and the signal potential (**25** in Fig. 1) varies at the same value whereby the carrier envelope $I\beta$ of Fig. 6 constitutes halfwave pulses due to the rectifying action of the emitter. It will be apparent, of course, that the potential bias across the emitter may be such that the signal (**25** in Fig. 1) merely changes the relative intensity of the emission so that the envelope $I\beta$ would represent full sine waves.

In the above example, the cell **45** is a photo-emissive cell and accordingly the frequency of the light emanations from the emitter E may vary at a high rate depending upon the limit of the crystalline emitter, which has been found to be higher than 2,000,000 cycles per second.

The network in Fig. 5 may alternatively be used in an analogue computer mechanism as a component in substitute for present conventional type function generator networks. As previously described, the Fig. 5 network produces a photocurrent which is the instantaneous product of the signals E_A and E_B and the system is inherently adapted for use in integration operations of the nature V_Z=to $Kf(V_XV_Y)$, where f stands for a predetermined functional variation. In accordance with the instant invention the current I_A in accordance with voltage E_A may constitute the variable factor V_X, while the voltage E_B will constitute the variable factor V_Y, the product function V_Z being represented by the output of the network E_O. In this instance the predetermined functional variation f may be provided by variations in the impedance components of the network, as for example, resonant circuits which may still maintain a balanced condition for zeroing the dark current of the cell.

Preferably, however, the functional component is introduced by the element **50** which may constitute a variable impedance of the varistor type. Commercially available varistors vary widely in their inherent characteristics and can be manufactured to contain desirable characteristics within wide limits. Further, the varistor resistance may be independent of polarity or not, as desired. As a result the output voltage E_O, developed across the varistor, will vary as the product of the function represented by the varistor characteristics and the photocurrent of collector cell C.

Figs. 7, 8 and 9 illustrate other applications of the instant invention to components of analogue computer mechanisms. In Fig. 7 the emitter E is mounted in one leg of a balanced network in a position directly opposing the collector cell C in an adjacent leg of the network. A variable voltage E_A is then superimposed across the terminals of the network in a manner similar to that previously described to produce an output across a null resistor **50′**. This form of the invention differs, however, from that described in Fig. 5 in that no external bias or signal source is used for the semi-conductor light source E and reliance is placed upon the variation of the network parameters Z_1 through Z_4, inclusive, to provide the proper potential drop across the light source E.

This form of the invention represents another type of function generator in which the output voltage E_O, developed across the null resistor **50′**, may vary as a direct function of the input voltage E_A. This results from the fact that the voltage E_B, developed across the emitter, is in turn dependent upon the input voltage E_A and the circuit parameters. The voltage E_B in turn controls the emission of light and since the output of collector cell C is proportional to the applied potential of field E_A and the incident light intensity from emitter E, the potential across resistor **50′** will vary as a direct function of the input voltage E_A, i.e. $E_O=f(E_A)$. Various types of functions may be introduced into the network by the choice of suitable parameter values in a manner well known in the art, as for example, by the use of simple impedance parameters such as tuned circuits, varistors and bolometers.

An obvious advantage of the instant invention is as a substitute for conventional photoformers resulting in a great saving in space and weight in addition to eliminating the need for the complexity of control networks which are a necessary incident to the use of the cathode ray tubes in such photoformers.

Fig. 8 illustrates a further analogue computer component which may constitute a substitute for present multipliers of the curvature modulator type. As illustrated, the semiconductor light source E is positioned directly opposite a collector cell C and is connected through a terminal to an input voltage representing a value X_2. This value is subjected to the modulating action of the signal generator **125** connected across the semiconductor barrier in the manner described with respect to Fig. 1 to produce luminescence of an intensity varying in accordance with the term $KX_2 \sin \omega_c t$. This value is received by the collector cell C in the form of incident light. The cell is in turn energized by an applied potential representing the value X_1, whereby the resultant photocurrent output may represent the product of the values mixed in the collector and equal to $k'X_1X_2 \sin \omega_c t$. The value X is preferably applied to cell C via a network. This product value is then fed into a phase sensitive detector wherein the sine wave variations are removed to produce an output equal to $k''X_1X_2$.

The instant invention is also eminently suitable for use as a limiter in function generator circuits (as described previously) wherein no luminescence may occur unless and until the bias or signal voltage reaches a specific value, and due to the fact that the photocurrent produced in the collector cell C (particularly when using vacuum-emissive or photo-conductive types) has an upper limit of generation beyond which increased intensities are ineffective. Thus the combined emitter and collector permit an input signal emitter as a unit pulse to have a generated output signal limited to a definite value.

Fig. 9 illustrates a further modification of the invention which is also particularly useful in analogue computers. The figure depicts an amplification network containing sections corresponding to conventional cascaded D.C. amplifiers which are used to step up the D.C. values. In conventional circuits, however, it is necessary to maintain a common ground level which is difficult to attain without using complex wiring arrangements. The instant invention obviates such difficulty by coupling the respective sections in series relationship through an emitter E and collector cell C, as previously described. As shown, an initial light source circuit **5′** energizes an emitter E in accordance with a control signal E_S. This signal is then relayed through the succeeding amplification stages Z, Z′ and Z″ by the photon coupling between the respective collectors and emitters. As a result all stages may be maintained at a common ground level as shown.

Alternately, the sections Z, Z′ and Z″ may comprise separate stages of D.C. vacuum or gas tube amplifiers wherein the direct coupling is provided via the emitters and collectors. The amplifier sections Z, Z′ and Z″ may constitute balanced bridge networks as described previously with respect to Figs. 5 and 7, in which case the amplification is obtained by virtue of the photon modulation per se. It is thus possible to use the same plate voltage supply for all stages, a feat which is difficult to accomplish with conventional cascading circuits.

7

The form of the invention illustrated in Fig. 10 represents a simple frequency analyzer unit employing a balanced bridge network of the Wien type. Here, the varying potential applied across the emitter E of light source **105** may constitute a complex wave having multiple frequency components, while the signal voltage E_B, applied across the input terminal of the bridge, may constitute a fixed frequency signal of variable magnitude provided by a sine wave generator. As is well known, a superimposition of sine waves having amplitudes equal to E_A and E_B with the difference frequency equal to $\omega/2\pi$ results in the production of a modulated envelope having a value equal to the square root of the sum of the squares of the average input signals plus twice the product of such signals at the beat or difference frequency. The shape is identical to the wave output of a full wave rectifier when the superimposed voltages are of equal magnitude and will approach a sine wave variation only when the amplitude of one is extremely small as compared to the other.

The bridge signal E_B may be adjusted to equal the desired frequency component contained in signal E_A to provide a convenient means for ascertaining the value of such component by rectifying the output derived across the null points of the bridge, as by means of a detector **150**. The output of the rectifier will therefore vary in magnitude at the difference frequency (in this case zero) and may consequently be measured in the output circuit of the detector as a D.C. value. This rectified current is also a function of the phase relationship between the components E_A and E_B of equal frequency. Thus by incorporating a phase shifting circuit (not illustrated) with the sine wave generator, it is possible to not only compare the amplitude of the various frequencies but also their phase relationship to the signal E_B.

This phase shifting device alternatively may be incorporated into the bridge as one of the legs. By this means the output voltage developed across the null points may be shifted in the phase from 0° to 180° with no change in amplitude. In some instances (high frequency work), it will be desirable to use a twin T-network in lieu of that illustrated.

Preferably the detector **150** includes an output circuit having a variable resistance by which residual D.C. due to the plate circuit bias may be balanced out in the absence of a signal voltage.

A convenient and efficient arrangement for a frequency analyzer according to the instant invention may comprise a semi-conductor light source having means for varying the emitted light intensity at a signal value equal to a superimposition of various frequencies, a light-sensitive collector cell of the photo-voltaic type and a crystal detector. In this instance, the output developed across the null points of the bridge may be controlled to lie in the millivolt region, which region is also the most effective value for utilizing crystal detectors as square wave rectifiers. The entire device will be a size which compares favorably with printed circuit techniques; the bridge and network components may be provided by the use of screening, plating or painting methods used in commercial printed circuits. Further, since it is only necessary to compare wave components, the bias of the signal voltages may be kept low.

A further form of the invention may comprise a high impedance potential source connected across a plurality of semi-conductor light sources in series. The light quanta emitted from each source may be collected by a single cell to produce a photocurrent equal to the summation of emissions from all cells. In this manner, good amplification may be obtained. The sources may be physically oriented to balance out any emission delay factor.

It will be apparent that semiconductor light sources, such as are described in said copending application (e.g. graded seal junction) may be used as the light-sensitive

8

photo-conductive cell in lieu of the types previously mentioned. In such case, the dual material silicon-germanium or selenium-tellurium cell provides an added advantage in that each such cell unit has a separate absorption edge for each of the matrix materials whereby its utility is doubled. These graded seal junction semiconductors may thus be used with two different source wave lengths corresponding to the absorption edge of each matrix material.

Alternately, a photo-modulation unit such as that disclosed in said copending application and which includes a long wave length light source and an interposed semiconductor light modulator may be substituted for the instant type light source, as for example, in place of the circuit 5 in Fig. 5. In such case the collector cell C would preferably comprise a germanium light sensitive semiconductor biased in the blocking direction. With this arrangement an infrared light source would be positioned to direct a light beam of approximately 1.5 microns adjacent the barrier region of the cell C, after passing through a silicon semiconductor modulator biased in the forward direction at a value and rate dependent upon the intelligence desired to be transmitted. The light beam incident upon the cell C would thus be modulated by the photo-modulator in a manner more fully described in said copending application to produce a photocurrent in the bridge circuit of Fig. 5 dependent upon the modulated incident light beam and the normal current flow in the cell due to the biasing potential.

As many apparently widely different embodiments of this invention may be made without departing from the spirit and scope hereof, it is to be understood that the above invention is not limited, except as defined in the appended claims.

What is claimed is:

1. A photon modulation system including a semi-conductor light source, a light-sensitive cell for producing a photo current dependent upon applied electrode potential and incident light, an impedance network, means providing a potential having a band of frequency components for modulating the intensity of the light emitted from said light source, means for providing a potential across said light-sensitive cell of a fixed frequency and adjustable amplitude whereby said cell produces a photo current in said network which is proportional to the instantaneous summation of said modulations said impedance network including phase shifting means and a square law detector to detect any band frequency component at said fixed frequency.

2. A photon modulation system including a semi-conductor light source, having a substantially linear relationship between light output and current, a light-sensitive cell arranged to receive light from said light source for producing a photo current dependent upon applied electrode potential and incident light, an impedance network connected to said cell, means for providing a potential comprising a band of frequency components to be analyzed for modulating the intensity of the light emitted from said light source and means for providing a potential of adjustable frequency and adjustable amplitude across said light-sensitive cell and a square law detector connected in said network to detect any band frequency component which is the same frequency as said potential of adjustable frequency, whereby the amplitude of each frequency component in said band of frequency components may be determined.

3. The combination set forth in claim 2 in which said network includes phase shifting means whereby the phase and amplitude of each frequency component in said band of frequency components may be determined.

SECTION I

CONSIDER a crystal volume V, in the shape of a cube with the edge L, thought to be repeated with the period L in all (x, y, z) directions. (This is the scheme of F. Bloch, cf. Sh., pp. 129–153. We put Sh.'s $A_x = A_y = A_z$, and write L for these.) Let d be the lattice constant (this is Sh.'s a), then $L = Nd$, $N = 1, 2, \cdots$. (Sh.'s $N_x = N_y = N_z$, we write N for these.) The general crystal-invariant translation of the general point $\vec{r} = (x, y, z)$ (x, y, z are only defined mod L) is $\vec{r} \rightarrow \vec{r} + d\vec{j}$, where $\vec{j} = (j_x, j_y, j_z)$, with $j_x, j_y, j_z = 0, \pm 1, \pm 2, \cdots$, and only defined mod N. (Sh.'s i, j, k are these j_x, j_y, j_z.) We choose the complete set of stationary state wave functions (eigenfunctions) for electrons in the field of this crystal so, that for the state a, i.e., the eigenfunction ψ_a, the crystal-invariant translation $\vec{r} \rightarrow \vec{r} + \vec{d}_j$ merely multiplies ψ_a by a constant factor of absolute value 1, $\Theta(\vec{j})$:

$$\psi_a \rightarrow \Theta(\vec{j})\, \psi_a.$$

Then necessarily

$$\Theta(\vec{j}) = \exp\left(\frac{2\pi i}{N}(\vec{n} \cdot \vec{j})\right)$$

where

$$\vec{n} = (n_x, n_y, n_z)$$

with

$$n_x, n_y, n_z = 0, \pm 1, \pm 2, \cdots,$$

and only defined mod N.

We can also write

$$\Theta(\vec{j}) = \exp\left(\frac{2\pi i}{h}(\vec{P} \cdot d\vec{j})\right)$$

where

$$\vec{P} = \frac{h}{L}\,\vec{n}. \tag{1}$$

$\vec{P}$ is the "crystal-momentum" of the state a.

SECTION II

A Brillouin-Zone B contains precisely 2 (opposite spin) states for each $\vec{P}$, i.e., for each $\vec{j}$. Hence the total number of its states is $2N^3 = 2L^3/d^3$, i.e., $2/d^3$ states per unit volume.

The energy of the state a, E_a, is a function of $\vec{j}$, or equivalently of $\vec{P}$. We write it in the latter form:

$$E_a = F(\vec{P}).$$

The points

$$\text{I:} \quad n_x = n_y = n_z = O(\text{mod } N), \quad \text{i.e.,}$$

$$P_x = P_y = P_z = O\left(\text{mod } \frac{h}{a}\right)$$

and

$$\text{II:} \quad n_x = n_y = n_z = \frac{N}{2}(\text{mod } N)$$

(we assume, for the sake of simplicity, that N is even), i.e.,

$$P_x = P_y = P_z = \frac{h}{2d}\left(\text{mod } \frac{h}{d}\right)$$

are of special significance—E_a assumes its maximum and its minimum at I and at II, respectively, or at II and at I, respectively. We introduce $\vec{n}'$ and $\vec{P}' = (h/L)\,\vec{n}'$, as follows:

$$\text{For I:} \quad \vec{n}' = \vec{n}, \quad \text{i.e.,} \quad \vec{P}' = \vec{P}.$$

$$\text{For II:} \quad \vec{n}' = \vec{n} - \frac{N}{2}(1, 1, 1), \quad \text{i.e.,}$$

$$\vec{P}' = \vec{P} - \frac{h}{2d}(1, 1, 1).$$

At the maximum, i.e., the upper edge of the zone,

$$E_a = V^u = \frac{1}{2m}|\vec{P}'|^2, \tag{2}$$

at the minimum, i.e., the lower edge of the zone,

$$E_a = V^e = \frac{1}{2m}|\vec{P}'|^2. \tag{3}$$

Here m is the equivalent mass of the hole or the electron, respectively, but it is actually adequately approximated for our present purposes by the mass of the electron (Sh., pp. 176–182, 398).

SEMICONDUCTOR MASER WITH MODULATING MEANS

Walter Heywang, Munich, Germany, assignor to Siemens und Halske Aktiengesellschaft, Berlin and Munich, a corporation of Germany
Filed Apr. 22, 1959, Ser. No. 808,255
Claims priority, application Germany Apr. 30, 1958
16 Claims. (Cl. 332—52)

This invention relates to the control of very high frequency radiation and is particularly concerned with producing or amplifying very high frequency radiation according to the principle of microwave amplification by stimulated emission of radiation briefly referred to as "Maser" principle.

Arrangements operating in accordance with this principle make use of the fact that, when a particle, for example, an electron, is by radiation stimulated to pass from a term of higher energy content to a term of lower energy content, a radiation will be transmitted which corresponds to the energy difference of both terms, such radiation being often stronger than the stimulating radiation, the frequencies of the transmitted and of the stimulating radiation being the same.

Continuous transmission of radiation may be obtained by an auxiliary radiation which is in turn effective to cause particles to pass from the term of lower energy content to a term with an energy content exceeding that of the term from which the particles due to the stimulating radiation pass again into the lower energy content.

The various objects and features of the invention will appear in the course of the description which will be rendered below with reference to the accompanying drawing. In the drawing,

FIG. 1 shows an example of the manner in which a continuous transmission of radiation may be effected;

FIGS. 2*a* and 2*b* illustrate an embodiment of the invention; and

FIGS. 3, 4 and 5 show further embodiments of the invention.

Referring now to FIG. 1, showing in schematic representation the manner of effecting continuous transmission of radiation, terms *a*, *b*, *c* are indicated by short horizontal lines, the energy content of these terms decreasing from the top downwardly. The term *a* accordingly corresponds to an energy content greater than that of *b*, and *b* has an energy content exceeding that of *c*. In this arrangement, a particle (electron) is by auxiliary radiation lifted from the term *c* to the term *a* (see arrow 1), such electron thereupon dropping to the term *b* (see arrow 2), where it adheres. The stimulating radiation, which corresponds to the energy spacing between the terms *b* and *c*, thereupon causes this electron to pass from *b* to *c* (see arrow 3), thereby effecting transmission of amplified radiation the frequency of which as well as that of the stimulating radiation corresponds to the energy spacing E_{bc} between the term *b* and *c*, according to the known formula $E_{bc}=h\cdot\nu$, wherein h is Plank's constant and ν the frequency. Additional information with respect thereto may be found in the book entitled "Introduction to Solid State Physics," by Charles Kittel (University of California), published 1956 by Wiley, New York, page 122. The fact that the lifting of the electron on its path from *c* to *a* requires a greater energy than is liberated upon passage from *b* to *c*, shows that the auxiliary radiation for the lifting of the electron must have greater power than the radiation transmitted upon passage of the electron from *b* to *c*. However, the fact that the frequency of the auxiliary radiation by which the electron is lifted from *c* to *a* must be in accordance with the equation $\nu_{ca}\cdot h=E_{ca}$ higher than that of the transmitted radiation, is in such an arrangement more disturbing. The advantage of continuous transmission of a high frequency radiation is accordingly obtained at the expense of the serious drawback of having to provide for an auxiliary radiation which must not only have very high power but also a higher frequency.

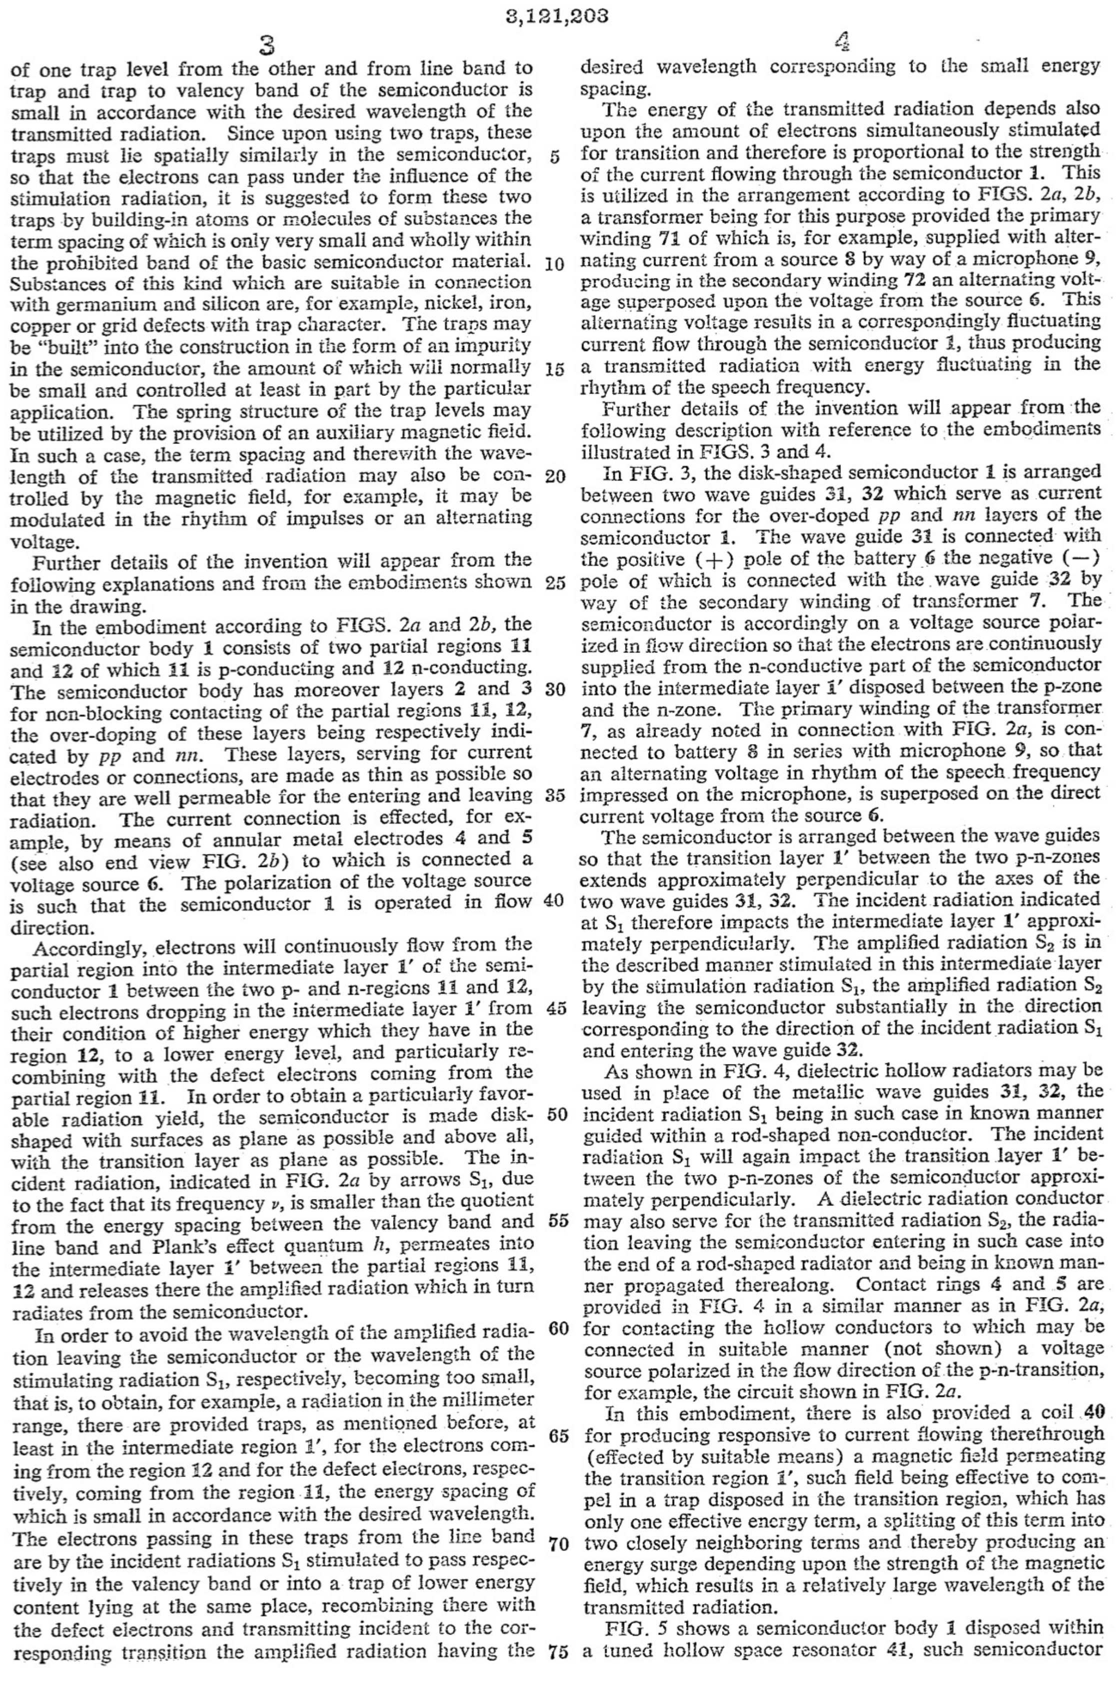
The invention avoids these disadvantages in most surprisingly simple manner by providing an arrangement for amplifying very high frequency radiation according to the Maser principle, comprising (*a*) an electron-conducting, particularly a mono-crystalline semi-conductor body having two mutually different regions in which the charge carriers have upon current flow through the semiconductor body different energy content, and in whose transition or junction area between these two regions the charge carriers of higher energy can be responsive to stimulation with high frequency radiation give off an amplified energy radiation of the same frequency; (*b*) a voltage source for effecting flow of charge carriers from the region of higher energy to the transition area; and (*c*) a radiation source the high frequency radiation of which permeates at least into the transition area of the semiconductor body.

The advantage resulting from the above noted features is that electrons of higher energy are by the voltage source continuously introduced into the transition zone between the two partial areas of the semiconductor body, these areas, under the influence of the stimulation radiation entering into the transition zone, passing to lower energy stages while giving off the amplified radiation, for example, recombining with positive charge carriers, and that maintenance of the radiation merely requires continuous current flow through the semiconductor body. The voltage placed on the semiconductor body is preferably a direct current voltage; however, for the modulation of the high frequency radiation transmitted from the semiconductor body, it may preferably fluctuate in the rhythm of the desired modulation frequency. Impulsewise transmission of radiation may be effected by placing on the semiconductor body which is continuously irradiated by a weak stimulation radiation, an alternating voltage or voltage impulses to provide in this manner for the transmission of high frequency radiation impulses.

Basic semiconductor materials very well adapted for arrangements according to the invention include known substances adapted for diodes and transistors, for example, silicon, germanium, $A^{III}B^{V}$-compounds and, in addition other semiconductor substances, for example, bismuthtellurid (Bi_2Te_3). The latter substance is particularly well adapted for purposes of the invention since it exhibits only a slight spacing between the valency band and the line band and having relative to the first mentioned substances only a slight heat conductivity, thereby further favoring the Maser effect.

In order to obtain in the semiconductor body regions of different energy content of the charge carriers, it will be advisable to use a semiconductor body having a p-zone and an n-zone. However, since the frequency of the stimulation radiation and the frequency of the transmitted radiation are, as noted before, in a fixed relationship to the energy loss suffered by the electron, stimulated by the permeating radiation, upon transition of the electron into the term of lower energy content, and since this frequency corresponds in the case of germanium or silicon to a wavelength of about 1 μm, it is for obtaining long wave radiation advisable to provide traps in the transition region between the two p- and n-zones. As explained in the book of Kittel, page 515, first paragraph, traps are impurity atoms or other imperfections in the crystal, the energy level of which may be at times occupied by electrons or holes. Traps are produced as impurities, for example, in silicon or germanium, by the building-in of nickel-, iron- and/or copper atoms. The energy spacing

Figure B.234: Walter Heywang filed detailed patent applications on laser diodes in 1958.



of one trap level from the other and from line band to trap and trap to valency band of the semiconductor is small in accordance with the desired wavelength of the transmitted radiation. Since upon using two traps, these traps must lie spatially similarly in the semiconductor, so that the electrons can pass under the influence of the stimulation radiation, it is suggested to form these two traps by building-in atoms or molecules of substances the term spacing of which is only very small and wholly within the prohibited band of the basic semiconductor material. Substances of this kind which are suitable in connection with germanium and silicon are, for example, nickel, iron, copper or grid defects with trap character. The traps may be "built" into the construction in the form of an impurity in the semiconductor, the amount of which will normally be small and controlled at least in part by the particular application. The spring structure of the trap levels may be utilized by the provision of an auxiliary magnetic field. In such a case, the term spacing and therewith the wavelength of the transmitted radiation may also be controlled by the magnetic field, for example, it may be modulated in the rhythm of impulses or an alternating voltage.

Further details of the invention will appear from the following explanations and from the embodiments shown in the drawing.

In the embodiment according to FIGS. 2*a* and 2*b*, the semiconductor body 1 consists of two partial regions 11 and 12 of which 11 is p-conducting and 12 n-conducting. The semiconductor body has moreover layers 2 and 3 for non-blocking contacting of the partial regions 11, 12, the over-doping of these layers being respectively indicated by *pp* and *nn*. These layers, serving for current electrodes or connections, are made as thin as possible so that they are well permeable for the entering and leaving radiation. The current connection is effected, for example, by means of annular metal electrodes 4 and 5 (see also end view FIG. 2*b*) to which is connected a voltage source 6. The polarization of the voltage source is such that the semiconductor 1 is operated in flow direction.

Accordingly, electrons will continuously flow from the partial region into the intermediate layer 1′ of the semiconductor 1 between the two p- and n-regions 11 and 12, such electrons dropping in the intermediate layer 1′ from their condition of higher energy which they have in the region 12, to a lower energy level, and particularly recombining with the defect electrons coming from the partial region 11. In order to obtain a particularly favorable radiation yield, the semiconductor is made disk-shaped with surfaces as plane as possible and above all, with the transition layer as plane as possible. The incident radiation, indicated in FIG. 2*a* by arrows S_1, due to the fact that its frequency ν, is smaller than the quotient from the energy spacing between the valency band and line band and Plank's effect quantum h, permeates into the intermediate layer 1′ between the partial regions 11, 12 and releases there the amplified radiation which in turn radiates from the semiconductor.

In order to avoid the wavelength of the amplified radiation leaving the semiconductor or the wavelength of the stimulating radiation S_1, respectively, becoming too small, that is, to obtain, for example, a radiation in the millimeter range, there are provided traps, as mentioned before, at least in the intermediate region 1′, for the electrons coming from the region 12 and for the defect electrons, respectively, coming from the region 11, the energy spacing of which is small in accordance with the desired wavelength. The electrons passing in these traps from the line band are by the incident radiations S_1 stimulated to pass respectively in the valency band or into a trap of lower energy content lying at the same place, recombining there with the defect electrons and transmitting incident to the corresponding transition the amplified radiation having the desired wavelength corresponding to the small energy spacing.

The energy of the transmitted radiation depends also upon the amount of electrons simultaneously stimulated for transition and therefore is proportional to the strength of the current flowing through the semiconductor 1. This is utilized in the arrangement according to FIGS. 2*a*, 2*b*, a transformer being for this purpose provided the primary winding 71 of which is, for example, supplied with alternating current from a source 8 by way of a microphone 9, producing in the secondary winding 72 an alternating voltage superposed upon the voltage from the source 6. This alternating voltage results in a correspondingly fluctuating current flow through the semiconductor 1, thus producing a transmitted radiation with energy fluctuating in the rhythm of the speech frequency.

Further details of the invention will appear from the following description with reference to the embodiments illustrated in FIGS. 3 and 4.

In FIG. 3, the disk-shaped semiconductor 1 is arranged between two wave guides 31, 32 which serve as current connections for the over-doped *pp* and *nn* layers of the semiconductor 1. The wave guide 31 is connected with the positive (+) pole of the battery 6 the negative (−) pole of which is connected with the wave guide 32 by way of the secondary winding of transformer 7. The semiconductor is accordingly on a voltage source polarized in flow direction so that the electrons are continuously supplied from the n-conductive part of the semiconductor into the intermediate layer 1′ disposed between the p-zone and the n-zone. The primary winding of the transformer 7, as already noted in connection with FIG. 2*a*, is connected to battery 8 in series with microphone 9, so that an alternating voltage in rhythm of the speech frequency impressed on the microphone, is superposed on the direct current voltage from the source 6.

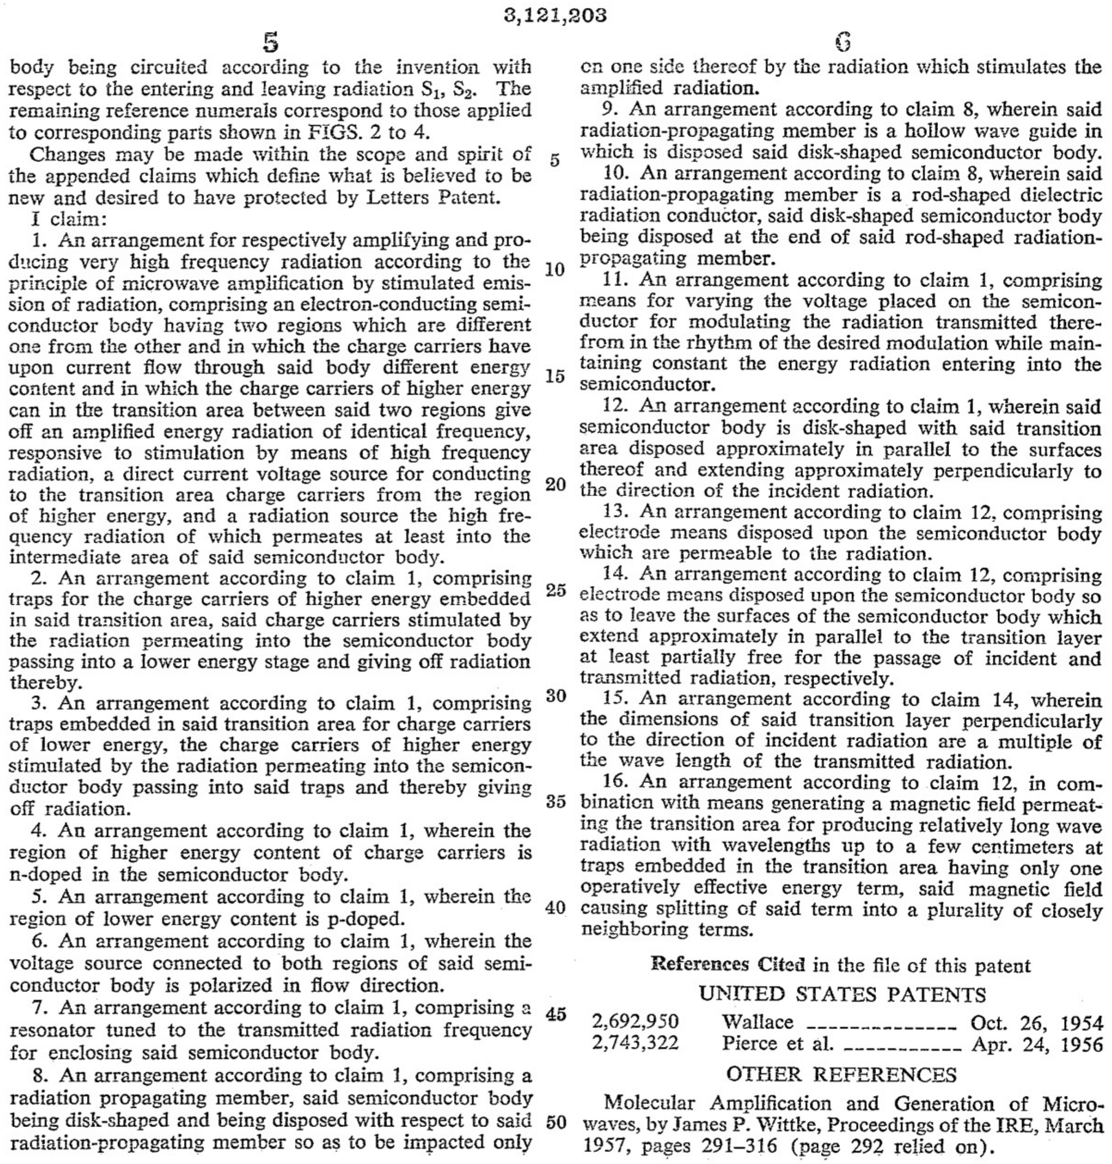
The semiconductor is arranged between the wave guides so that the transition layer 1′ between the two p-n-zones extends approximately perpendicular to the axes of the two wave guides 31, 32. The incident radiation indicated at S_1 therefore impacts the intermediate layer 1′ approximately perpendicularly. The amplified radiation S_2 is in the described manner stimulated in this intermediate layer by the stimulation radiation S_1, the amplified radiation S_2 leaving the semiconductor substantially in the direction corresponding to the direction of the incident radiation S_1 and entering the wave guide 32.

As shown in FIG. 4, dielectric hollow radiators may be used in place of the metallic wave guides 31, 32, the incident radiation S_1 being in such case in known manner guided within a rod-shaped non-conductor. The incident radiation S_1 will again impact the transition layer 1′ between the two p-n-zones of the semiconductor approximately perpendicularly. A dielectric radiation conductor may also serve for the transmitted radiation S_2, the radiation leaving the semiconductor entering in such case into the end of a rod-shaped radiator and being in known manner propagated therealong. Contact rings 4 and 5 are provided in FIG. 4 in a similar manner as in FIG. 2*a*, for contacting the hollow conductors to which may be connected in suitable manner (not shown) a voltage source polarized in the flow direction of the p-n-transition, for example, the circuit shown in FIG. 2*a*.

In this embodiment, there is also provided a coil 40 for producing responsive to current flowing therethrough (effected by suitable means) a magnetic field permeating the transition region 1′, such field being effective to compel in a trap disposed in the transition region, which has only one effective energy term, a splitting of this term into two closely neighboring terms and thereby producing an energy surge depending upon the strength of the magnetic field, which results in a relatively large wavelength of the transmitted radiation.

FIG. 5 shows a semiconductor body 1 disposed within a tuned hollow space resonator 41, such semiconductor

Figure B.235: Walter Heywang filed detailed patent applications on laser diodes in 1958.



body being circuited according to the invention with respect to the entering and leaving radiation S_1, S_2. The remaining reference numerals correspond to those applied to corresponding parts shown in FIGS. 2 to 4.

Changes may be made within the scope and spirit of the appended claims which define what is believed to be new and desired to have protected by Letters Patent.

I claim:

1. An arrangement for respectively amplifying and producing very high frequency radiation according to the principle of microwave amplification by stimulated emission of radiation, comprising an electron-conducting semiconductor body having two regions which are different one from the other and in which the charge carriers have upon current flow through said body different energy content and in which the charge carriers of higher energy can in the transition area between said two regions give off an amplified energy radiation of identical frequency, responsive to stimulation by means of high frequency radiation, a direct current voltage source for conducting to the transition area charge carriers from the region of higher energy, and a radiation source the high frequency radiation of which permeates at least into the intermediate area of said semiconductor body.

2. An arrangement according to claim 1, comprising traps for the charge carriers of higher energy embedded in said transition area, said charge carriers stimulated by the radiation permeating into the semiconductor body passing into a lower energy stage and giving off radiation thereby.

3. An arrangement according to claim 1, comprising traps embedded in said transition area for charge carriers of lower energy, the charge carriers of higher energy stimulated by the radiation permeating into the semiconductor body passing into said traps and thereby giving off radiation.

4. An arrangement according to claim 1, wherein the region of higher energy content of charge carriers is n-doped in the semiconductor body.

5. An arrangement according to claim 1, wherein the region of lower energy content is p-doped.

6. An arrangement according to claim 1, wherein the voltage source connected to both regions of said semiconductor body is polarized in flow direction.

7. An arrangement according to claim 1, comprising a resonator tuned to the transmitted radiation frequency for enclosing said semiconductor body.

8. An arrangement according to claim 1, comprising a radiation propagating member, said semiconductor body being disk-shaped and being disposed with respect to said radiation-propagating member so as to be impacted only on one side thereof by the radiation which stimulates the amplified radiation.

9. An arrangement according to claim 8, wherein said radiation-propagating member is a hollow wave guide in which is disposed said disk-shaped semiconductor body.

10. An arrangement according to claim 8, wherein said radiation-propagating member is a rod-shaped dielectric radiation conductor, said disk-shaped semiconductor body being disposed at the end of said rod-shaped radiation-propagating member.

11. An arrangement according to claim 1, comprising means for varying the voltage placed on the semiconductor for modulating the radiation transmitted therefrom in the rhythm of the desired modulation while maintaining constant the energy radiation entering into the semiconductor.

12. An arrangement according to claim 1, wherein said semiconductor body is disk-shaped with said transition area disposed approximately in parallel to the surfaces thereof and extending approximately perpendicularly to the direction of the incident radiation.

13. An arrangement according to claim 12, comprising electrode means disposed upon the semiconductor body which are permeable to the radiation.

14. An arrangement according to claim 12, comprising electrode means disposed upon the semiconductor body so as to leave the surfaces of the semiconductor body which extend approximately in parallel to the transition layer at least partially free for the passage of incident and transmitted radiation, respectively.

15. An arrangement according to claim 14, wherein the dimensions of said transition layer perpendicularly to the direction of incident radiation are a multiple of the wave length of the transmitted radiation.

16. An arrangement according to claim 12, in combination with means generating a magnetic field permeating the transition area for producing relatively long wave radiation with wavelengths up to a few centimeters at traps embedded in the transition area having only one operatively effective energy term, said magnetic field causing splitting of said term into a plurality of closely neighboring terms.

SOLID STATE RADIATION EMITTERS

Herbert Kroemer, Sunnyvale, Calif., assignor to Varian Associates, Palo Alto, Calif., a corporation of California

Filed Aug. 16, 1963, Ser. No. 302,647
20 Claims. (Cl. 313—108)

This invention relates to solid state radiation emitters, and in particular to novel and improved semiconductor devices that afford enhanced radiating characteristics.

Although the semiconductor device of this invention may be useful for various applications, the description will be directed to the use of the inventive device as a laser, for the purpose of description and explanation. It should be understood that the inventive concept is not limited to laser applications only.

Radiation or lasing action by semiconductors may be achieved in one way by the recombination of injected excess charge carriers. By exciting or stimulating certain semiconductors by means of light energy or electric current, these semiconductors will emit visible light, infrared, or other radiation.

However, radiating or lasing structures utilizing solid state devices have been limited to the direct gap type semiconductors, such as gallium arsenide, indium arsenide and indium phosphide, and to the semiconductor alloys $GaAs_xP_{1-x}$ and $Ga_xIn_{1-x}As$. It has not been possible to effect highly radiative recombination with the common semiconductors of the indirect energy gap type, such as Ge, Si, GaP for example, because a very high carrier injection level is required. The indirect gap type semiconductor is characterized in that an electron from the lowest energy state in the conduction band is not able to recombine radiatively with a hole in the highest energy state in the valence band. In order for the higher electron states to contain any electrons, it is necessary that very high carrier densities be injected, whereby the indirect gap semiconductors will be capable of emitting light by means of recombination.

Also, the presently known semiconductor radiation emitters or lasers are of the homojunction type, that is, the two sides of the PN junction are formed from a single semiconductor material. A homojunction structure cannot inject a higher carrier density than the doping density on the more heavily doped side of the semiconductor junction, and therefore, it is not possible to realize carrier densities or injection levels that are high enough to overcome the degeneracy threshold of the semiconductor, nor the even higher carrier densities needed to cause lasing in indirect gap semiconductors.

The degeneracy threshold may be defined as the injection level above which injected electrons fill more than half of the available electron states at the lower edge of the conduction band, and above which more than half of the electron states at the upper edge of the valence is empty, or filled with holes. The value of the degeneracy threshold varies with the semiconductor material being used. At room temperature, this value may be approximately 10^{18} carriers per cubic centimeter, by way of example. However, the degeneracy threshold decreases with a decrease in temperature, being approximately proportional to $T^{+3/2}$, where T is the absolute temperature. To achieve optimum efficiency, it is preferable to utilize an injected carrier density that is close to the degeneracy threshold. Furthermore, to accomplish coherent light emission, it is necessary that the injected carrier density

2

be greater than the degeneracy threshold. Since only limited injection levels are possible with conventional PN junctions, such as found in the presently known semiconductor lasers, the degeneracy threshold must be lowered by extreme cooling of the structure to provide a suitable injection level.

Thus it is obvious that if high injection densities were provided, there would be no need for the extreme cooling of semiconductor lasers down to cryogenic temperatures. Also, if high injection densities were provided, indirect gap type as well as direct gap type semiconductors could be made to radiate or lase coherently, and at ambient or room temperatures.

Furthermore, with presently known semiconductor lasers having homojunctions, the light is radiated from the end of the junction in a direction substantially perpendicular to the current flow. It would be desirable, as an alternative, to obtain coherent light that is emitted transversely relative to the junction surface of the lasing body and in the direction of current flow so that the light emission covers a substantially wide area.

An object of this invention is to provide novel and improved solid state radiation emitters.

Another object of this invention is to provide high density injection light-emitting structures characterized by increased operating efficiency.

Another object is to provide solid state light emitters and lasers that can operate at ambient temperatures.

A further object is to provide coherent laser devices that afford wide area emission.

According to this invention, a solid state radiation emitter device comprises a semiconductor base, and means for injecting charge carriers of high density into such base and for preventing the outflow of the injected carriers from the base, so that the charge carriers may be efficiently utilized in a radiative recombination process.

In one embodiment of the invention, a solid state radiation emitter includes a thin base or support formed from a first semiconductor material having a relatively low energy gap, and injector electrodes formed from another semiconductor material disposed on each side of such base to form heterojunctions. The injector electrode material is heavily doped and has a substantially wider energy gap than the base material. The pair of wider energy gap injector electrodes are preferably of opposite polarity, one being P-type and the other N-type. An external source of power such as direct electric current, is coupled to the injector electrodes for supplying a forward bias voltage to the emitter device. Thus, excess charge carriers may be injected with a high density so that the degeneracy threshold of the base material is overcome at ambient or room temperatures with resultant emission of radiation. In this manner, a highly efficient light-emitting action is obtained by recombination radiation with indirect gap type semiconductors as well as with direct gap semiconductors at ambient temperatures.

In another embodiment of the invention, the injector electrodes are doped to have the same polarity, and suitable biasing means are coupled to the injector electrodes and to the base to provide high density carrier injection to the base.

In specific embodiments of the invention, reflective or opaque conducting electrodes are disposed on the emitter device so that radiation is directed in predetermined configurations and directions.

It is recognized that various configurations are possible within the scope of the invention whereby injector elec-

Figure B.238: Herbert Kroemer invented the double-heterostructure laser diode in 1963.

trodes formed from a semiconductor material with a higher energy gap are disposed adjacent to a semiconductor base with a relatively lower energy gap, and energizing means are provided for actuating injection of high density charge carriers into the base. The injector electrodes are so located relative to the base that carrier outflow from the base and surface recombination are prevented.

The invention will be described in greater detail with reference to the drawing in which:

FIGURE 1 is a representational schematic diagram of a semiconductor laser, in accordance with this invention;

FIGURES 2 and 3 are isometric views, partly broken away, of embodiments of this invention;

FIGURES 4 and 5 are isometric views of alternative embodiments of the inventive structure;

FIGURE 6 is a sectional view of another alternative embodiment; and

FIGURES 7–9 are representational schematic diagrams of other embodiments of the invention.

Similar numerals refer to similar parts throughout the drawing. It is to be noted that the figures of the drawing are merely illustrative, and that the parts are not represented in exact proportion.

In the schematic diagram of FIGURE 1, a semiconductor radiation emitter structure, according to this invention, comprises a weakly doped base **10** formed from a lower energy gap material; a higher energy gap P-type injector electrode **12** on one surface of the base; and a higher energy gap N-type injector electrode **14** disposed on the opposite surface of the base **10**. A direct current source **16** supplies a positive potential to the P-type injector electrode **12**, whereas a negative potential is supplied to the N-type injector electrode **14**.

In one embodiment of the invention, the lasing base **10** is formed from a single crystal germanium (Ge) wafer, and the injector electrodes **12** and **14** are made from gallium arsenide (GaAs) that has been suitably doped. The junctions formed between the dissimilar materials are referred to as heterojunctions, in contrast to homojunctions. When manufacturing the inventive laser utilizing these particular materials, a pair of layers of GaAs are grown on a germanium wafer or base having a thickness of about 100 microns or less.

The GaAs layers are formed by first preparing a melt consisting of gallium with a small percentage of arsenic. The arsenic content in the melt depends on the growing temperature, which may range from 350° to 750° C. by way of example. At a growing temperature of 500° C., a mixture comprising approximately 5 atomic percent of arsenic is used. The prepared melt is slowly heated to about 600° C. so that the arsenic reacts with the gallium to form GaAs. (Alternatively, an appropriate amount of GaAs may be dissolved in gallium to provide a suitable mixture.) In order to dissolve the residual arsenic that has not reacted, the melt is stirred repeatedly for the first ten minutes of the slow heating process. When the melt reaches about 600° C., the temperature is maintained for at least ten minutes to allow the excess arsenic to be evaporated, and to remove any condensation nuclei. The temperature of the melt is then reduced rapidly by about 100° C., within a period of less than ten minutes. When the temperature of the melt approaches approximately 500° C., the Ge wafer is quickly immersed into the supercooled melt.

The wafer acts as a seed so that the GaAs grows on the wafer support epitaxially. Before immersion, the Ge wafer is heated to a temperature higher than the melt, i.e. over 600° C., for example. The wafer is left in the melt for at least one minute and then withdrawn, providing a GaAs layer that is about 5–20 microns thick, for example. The above steps are performed in a reducing atmosphere, such as in pure hydrogen.

It is known that commercial arsenic contains impurities which produce only N-type GaAs injector electrodes. To increase the intensity of the N-type doping whereby higher injection levels are realized, an N-type dopant such as tin is added to the melt in a 1% proportion relative to the mixture.

However, in order to obtain a highly efficient semiconductor laser, one of the two GaAs layers is preferably made as a P-type injector electrode **12** by diffusing a P-type dopant such as zinc therein. To introduce the Zn into the GaAs layer, the base wafer and Zn doping material are heated within an evacuated quartz ampoule at about 800° C. for about one hour. The Zn dopant may comprise an alloy of 90% indium and 10% zinc, where the zinc is the primary diffusant and the indium acts as a buffer to prevent excess Zn vapor pressure. In order to retain the N-type doping of the other GaAs injector electrode, the N-type layer is masked with a film of evaporated or vapor-deposited SiO_2 prior to the introduction of the Zn dopant. The Zn diffuses rapidly in the exposed GaAs layer, but relatively slowly in the Ge wafer, and the diffusion virtually stops at the Ge-GaAs junction interface. After diffusion, the SiO_2 masking film is removed from the N-type layer with hydrochloric acid.

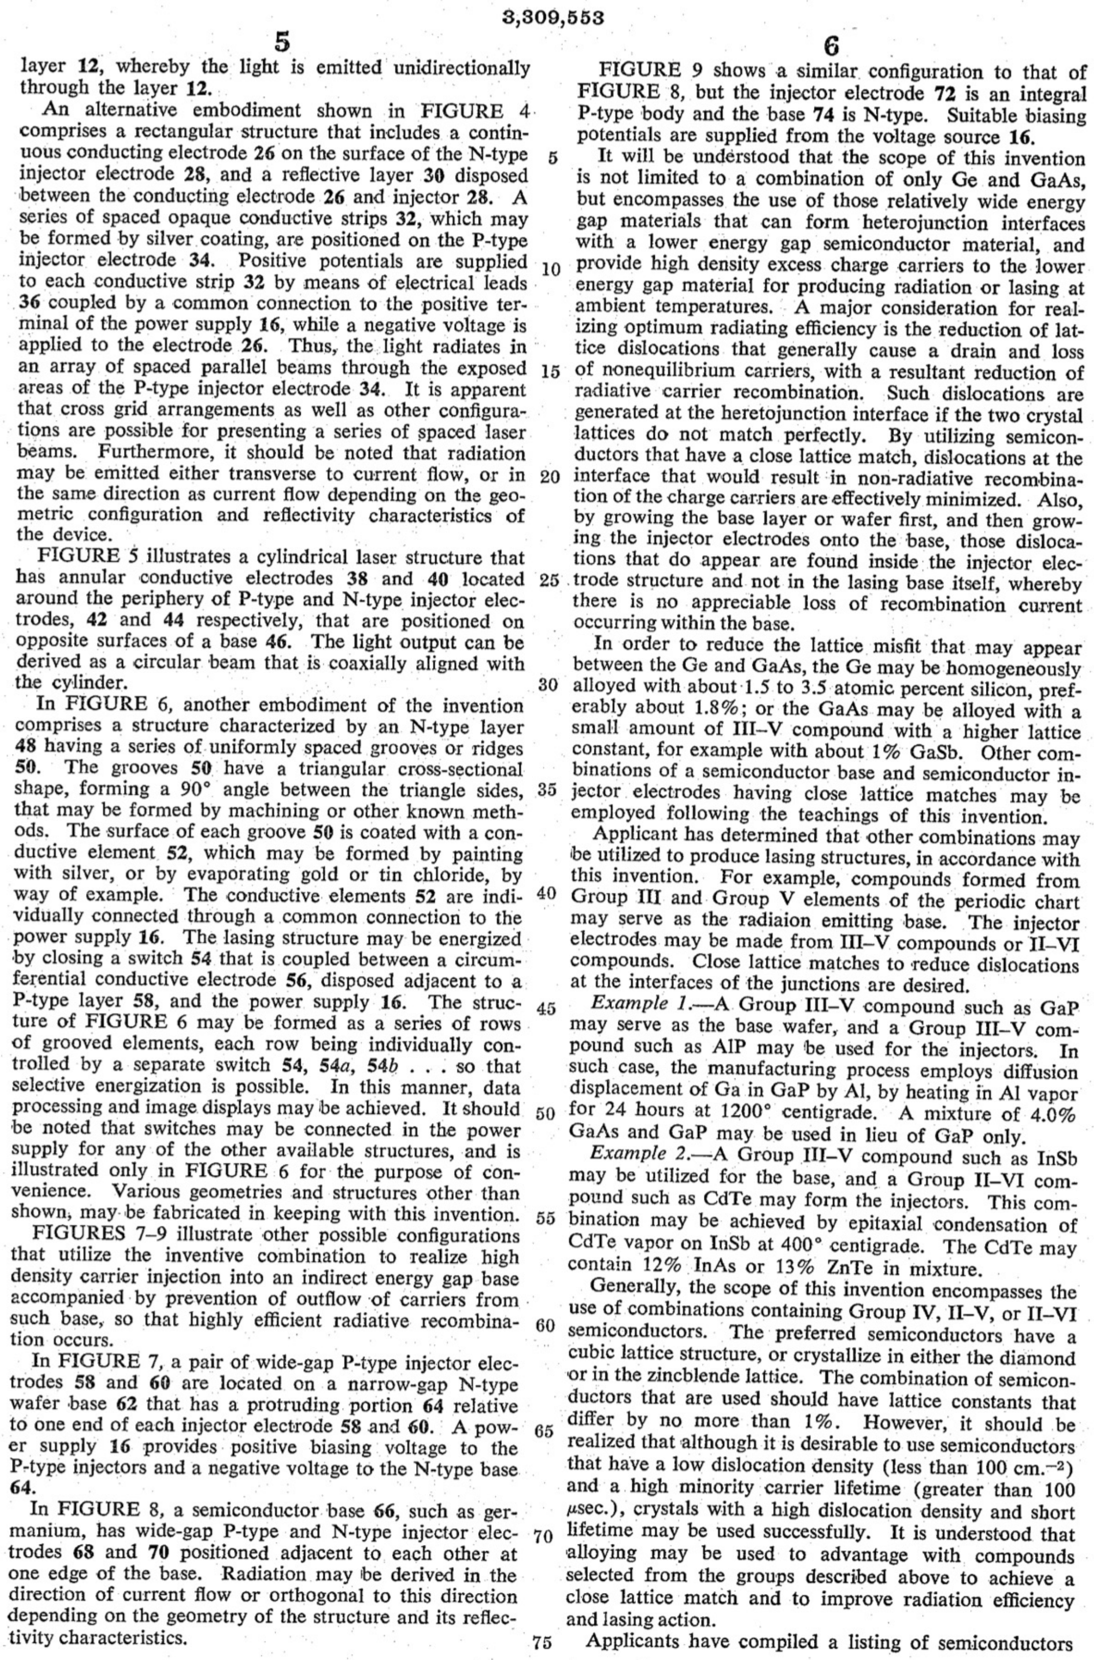
An alternative method of forming the semiconductor laser structure, with opposite polarity injector electrodes disposed on each side of a lasing base, employs a pair of Ge wafers that are placed back-to-back in a GaAs solution. N-type GaAs is grown on the exposed side of each wafer, while the surfaces that are positioned closely adjacent to each other are maintained unwetted. The edge surfaces also remain unwetted by coating the wafer edges with colloidal graphite. After growing suitable N-type injector electrodes, the wafers are then placed in a second GaAs solution that has been made P-type by adding one percent Zn, with the two coated N-type grown layers closely adjacent to each other in a back-to-back position. The P-type injector electrodes are then grown, and the graphite coating is subsequently removed from the edges of the two wafers. It is recognized that laser structure with injector electrodes may be produced by vapor epitaxy techniques.

After growing the injector electrode layers of opposite polarity, the structures are cut or cleaved to a desired shape or size, such as illustrated in FIGURES 2–6. Suitable conducting electrodes **18** and **20** are formed on the injector electrodes by evaporation, plating or other known means in any desired configuration, using screening or masking techniques. The electrodes may be formed by brushing or spraying silver paint or by evaporating thin conducting films, such as tin chloride or gold, in a well-known manner. The conducting electrodes may be made opaque or light-transmitting; or may be formed as a combination of opaque and transparent areas to allow selective areal transmission of light.

Various structures incorporating the inventive combination are shown in FIGURES 2–6. With reference to FIGURE 2, an embodiment of the invention includes a disk-like base structure **10** (shown in part) sandwiched between a P-type injector electrode **12** and N-type injector electrode **14.** Annular conducting electrodes **18** and **20**, which may be formed from silver paint, are disposed on the injector electrodes **12** and **14** respectively, and are connected to the terminals of a direct current supply **16.** Upon application of D.C. current, for example 1.0 volt, radiation or light is transmitted transversely to the plane of the base disk **10.** It is understood that the diameter of the base **10** may be of such length that the radiation is emitted radially from the base **10.**

FIGURE 3 illustrates a laser structure similar to that of FIGURE 2, but provides a continuous conducting electrode **22** covering the entire surface of the N-type injector electrode **14.** A reflecting layer **24**, formed from aluminum, for example, that has been positioned between the N-type injector layer **14** and the conductive electrode **22** serves to reflect the light radiation towards the P-type

Figure B.239: Herbert Kroemer invented the double-heterostructure laser diode in 1963.



layer **12**, whereby the light is emitted unidirectionally through the layer **12**.

An alternative embodiment shown in FIGURE 4 comprises a rectangular structure that includes a continuous conducting electrode **26** on the surface of the N-type injector electrode **28**, and a reflective layer **30** disposed between the conducting electrode **26** and injector **28**. A series of spaced opaque conductive strips **32**, which may be formed by silver coating, are positioned on the P-type injector electrode **34**. Positive potentials are supplied to each conductive strip **32** by means of electrical leads **36** coupled by a common connection to the positive terminal of the power supply **16**, while a negative voltage is applied to the electrode **26**. Thus, the light radiates in an array of spaced parallel beams through the exposed areas of the P-type injector electrode **34**. It is apparent that cross grid arrangements as well as other configurations are possible for presenting a series of spaced laser beams. Furthermore, it should be noted that radiation may be emitted either transverse to current flow, or in the same direction as current flow depending on the geometric configuration and reflectivity characteristics of the device.

FIGURE 5 illustrates a cylindrical laser structure that has annular conductive electrodes **38** and **40** located around the periphery of P-type and N-type injector electrodes, **42** and **44** respectively, that are positioned on opposite surfaces of a base **46**. The light output can be derived as a circular beam that is coaxially aligned with the cylinder.

In FIGURE 6, another embodiment of the invention comprises a structure characterized by an N-type layer **48** having a series of uniformly spaced grooves or ridges **50**. The grooves **50** have a triangular cross-sectional shape, forming a 90° angle between the triangle sides, that may be formed by machining or other known methods. The surface of each groove **50** is coated with a conductive element **52**, which may be formed by painting with silver, or by evaporating gold or tin chloride, by way of example. The conductive elements **52** are individually connected through a common connection to the power supply **16**. The lasing structure may be energized by closing a switch **54** that is coupled between a circumferential conductive electrode **56**, disposed adjacent to a P-type layer **58**, and the power supply **16**. The structure of FIGURE 6 may be formed as a series of rows of grooved elements, each row being individually controlled by a separate switch **54**, **54***a*, **54***b* . . . so that selective energization is possible. In this manner, data processing and image displays may be achieved. It should be noted that switches may be connected in the power supply for any of the other available structures, and is illustrated only in FIGURE 6 for the purpose of convenience. Various geometries and structures other than shown, may be fabricated in keeping with this invention.

FIGURES 7–9 illustrate other possible configurations that utilize the inventive combination to realize high density carrier injection into an indirect energy gap base accompanied by prevention of outflow of carriers from such base, so that highly efficient radiative recombination occurs.

In FIGURE 7, a pair of wide-gap P-type injector electrodes **58** and **60** are located on a narrow-gap N-type wafer base **62** that has a protruding portion **64** relative to one end of each injector electrode **58** and **60**. A power supply **16** provides positive biasing voltage to the P-type injectors and a negative voltage to the N-type base **64**.

In FIGURE 8, a semiconductor base **66**, such as germanium, has wide-gap P-type and N-type injector electrodes **68** and **70** positioned adjacent to each other at one edge of the base. Radiation may be derived in the direction of current flow or orthogonal to this direction depending on the geometry of the structure and its reflectivity characteristics.

FIGURE 9 shows a similar configuration to that of FIGURE 8, but the injector electrode **72** is an integral P-type body and the base **74** is N-type. Suitable biasing potentials are supplied from the voltage source **16**.

It will be understood that the scope of this invention is not limited to a combination of only Ge and GaAs, but encompasses the use of those relatively wide energy gap materials that can form heterojunction interfaces with a lower energy gap semiconductor material, and provide high density excess charge carriers to the lower energy gap material for producing radiation or lasing at ambient temperatures. A major consideration for realizing optimum radiating efficiency is the reduction of lattice dislocations that generally cause a drain and loss of nonequilibrium carriers, with a resultant reduction of radiative carrier recombination. Such dislocations are generated at the heretojunction interface if the two crystal lattices do not match perfectly. By utilizing semiconductors that have a close lattice match, dislocations at the interface that would result in non-radiative recombination of the charge carriers are effectively minimized. Also, by growing the base layer or wafer first, and then growing the injector electrodes onto the base, those dislocations that do appear are found inside the injector electrode structure and not in the lasing base itself, whereby there is no appreciable loss of recombination current occurring within the base.

In order to reduce the lattice misfit that may appear between the Ge and GaAs, the Ge may be homogeneously alloyed with about 1.5 to 3.5 atomic percent silicon, preferably about 1.8%; or the GaAs may be alloyed with a small amount of III–V compound with a higher lattice constant, for example with about 1% GaSb. Other combinations of a semiconductor base and semiconductor injector electrodes having close lattice matches may be employed following the teachings of this invention.

Applicant has determined that other combinations may be utilized to produce lasing structures, in accordance with this invention. For example, compounds formed from Group III and Group V elements of the periodic chart may serve as the radiaion emitting base. The injector electrodes may be made from III–V compounds or II–VI compounds. Close lattice matches to reduce dislocations at the interfaces of the junctions are desired.

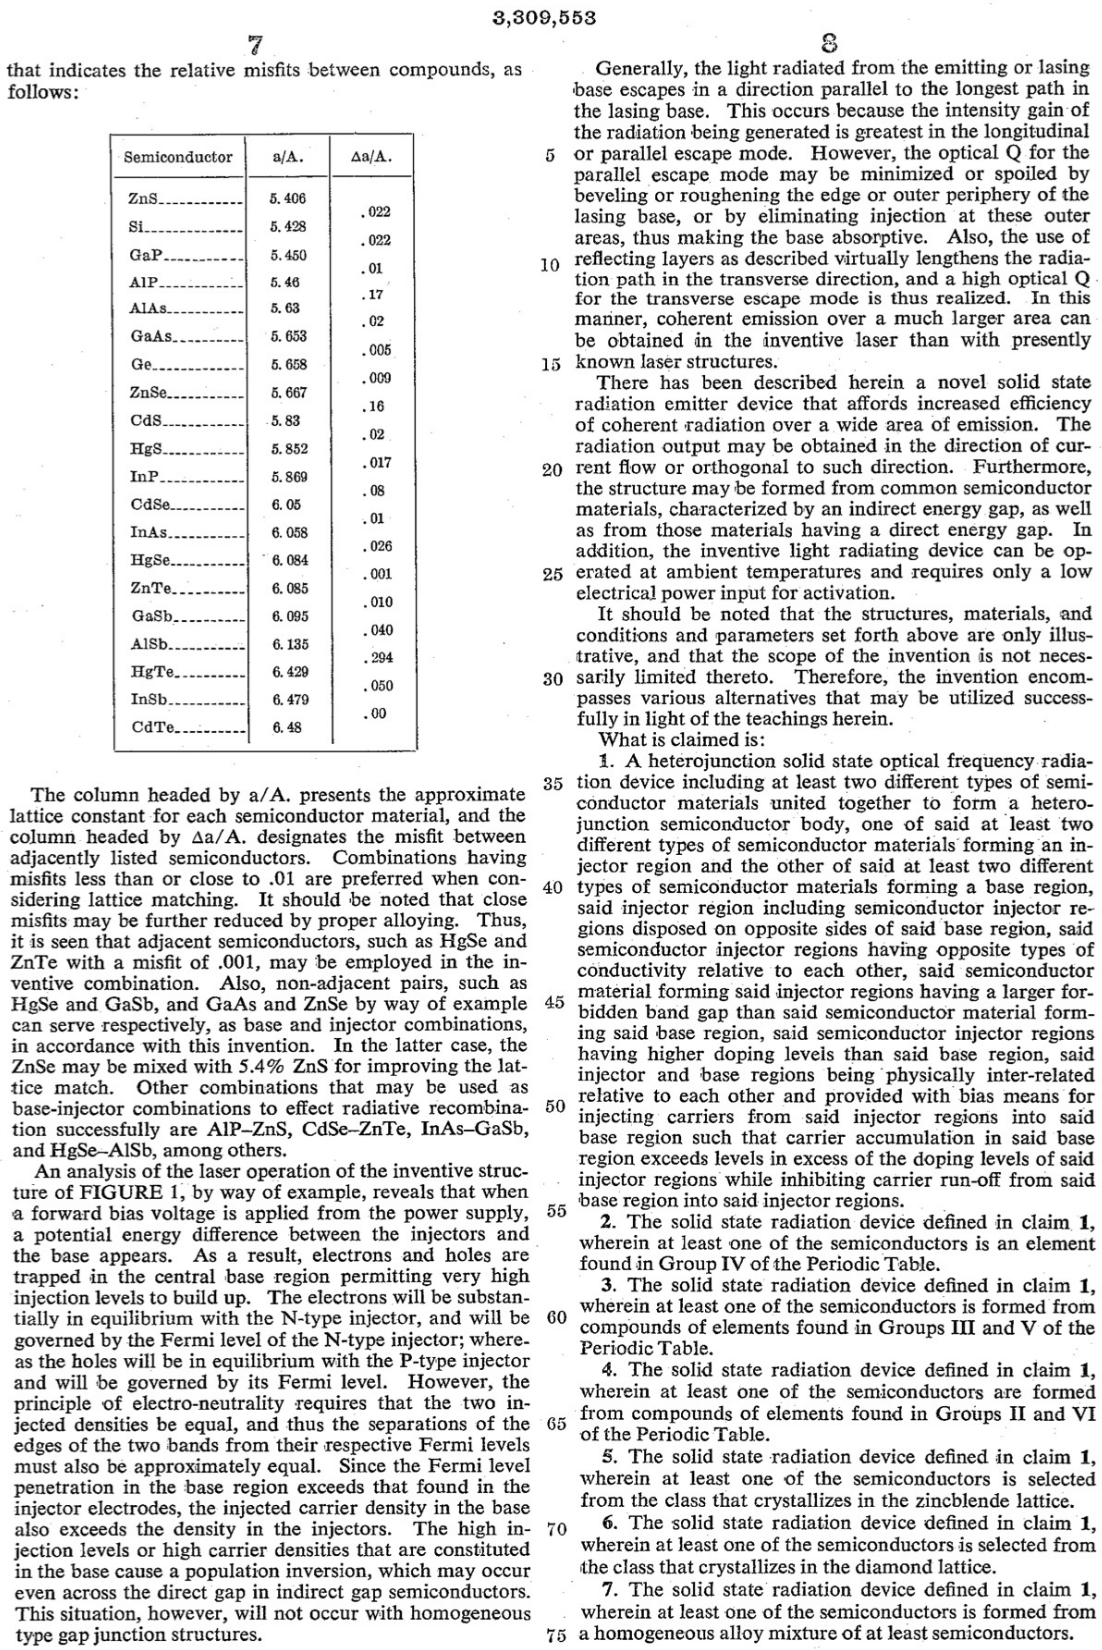
Example 1.—A Group III–V compound such as GaP may serve as the base wafer, and a Group III–V compound such as AlP may be used for the injectors. In such case, the manufacturing process employs diffusion displacement of Ga in GaP by Al, by heating in Al vapor for 24 hours at 1200° centigrade. A mixture of 4.0% GaAs and GaP may be used in lieu of GaP only.

Example 2.—A Group III–V compound such as InSb may be utilized for the base, and a Group II–VI compound such as CdTe may form the injectors. This combination may be achieved by epitaxial condensation of CdTe vapor on InSb at 400° centigrade. The CdTe may contain 12% InAs or 13% ZnTe in mixture.

Generally, the scope of this invention encompasses the use of combinations containing Group IV, II–V, or II–VI semiconductors. The preferred semiconductors have a cubic lattice structure, or crystallize in either the diamond or in the zincblende lattice. The combination of semiconductors that are used should have lattice constants that differ by no more than 1%. However, it should be realized that although it is desirable to use semiconductors that have a low dislocation density (less than 100 cm.$^{-2}$) and a high minority carrier lifetime (greater than 100 μsec.), crystals with a high dislocation density and short lifetime may be used successfully. It is understood that alloying may be used to advantage with compounds selected from the groups described above to achieve a close lattice match and to improve radiation efficiency and lasing action.

Applicants have compiled a listing of semiconductors

Figure B.240: Herbert Kroemer invented the double-heterostructure laser diode in 1963.



that indicates the relative misfits between compounds, as follows:

Semiconductor	a/A.	Δa/A.
ZnS	5.406	
		.022
Si	5.428	
		.022
GaP	5.450	
		.01
AlP	5.46	
		.17
AlAs	5.63	
		.02
GaAs	5.653	
		.005
Ge	5.658	
		.009
ZnSe	5.667	
		.16
CdS	5.83	
		.02
HgS	5.852	
		.017
InP	5.869	
		.08

		.00
CdTe	6.48	

The column headed by a/A. presents the approximate lattice constant for each semiconductor material, and the column headed by Δa/A. designates the misfit between adjacently listed semiconductors. Combinations having misfits less than or close to .01 are preferred when considering lattice matching. It should be noted that close misfits may be further reduced by proper alloying. Thus, it is seen that adjacent semiconductors, such as HgSe and ZnTe with a misfit of .001, may be employed in the inventive combination. Also, non-adjacent pairs, such as HgSe and GaSb, and GaAs and ZnSe by way of example can serve respectively, as base and injector combinations, in accordance with this invention. In the latter case, the ZnSe may be mixed with 5.4% ZnS for improving the lattice match. Other combinations that may be used as base-injector combinations to effect radiative recombination successfully are AlP–ZnS, CdSe–ZnTe, InAs–GaSb, and HgSe–AlSb, among others.

An analysis of the laser operation of the inventive structure of FIGURE 1, by way of example, reveals that when a forward bias voltage is applied from the power supply, a potential energy difference between the injectors and the base appears. As a result, electrons and holes are trapped in the central base region permitting very high injection levels to build up. The electrons will be substantially in equilibrium with the N-type injector, and will be governed by the Fermi level of the N-type injector; whereas the holes will be in equilibrium with the P-type injector and will be governed by its Fermi level. However, the principle of electro-neutrality requires that the two injected densities be equal, and thus the separations of the edges of the two bands from their respective Fermi levels must also be approximately equal. Since the Fermi level penetration in the base region exceeds that found in the injector electrodes, the injected carrier density in the base also exceeds the density in the injectors. The high injection levels or high carrier densities that are constituted in the base cause a population inversion, which may occur even across the direct gap in indirect gap semiconductors. This situation, however, will not occur with homogeneous type gap junction structures.

Generally, the light radiated from the emitting or lasing base escapes in a direction parallel to the longest path in the lasing base. This occurs because the intensity gain of the radiation being generated is greatest in the longitudinal or parallel escape mode. However, the optical Q for the parallel escape mode may be minimized or spoiled by beveling or roughening the edge or outer periphery of the lasing base, or by eliminating injection at these outer areas, thus making the base absorptive. Also, the use of reflecting layers as described virtually lengthens the radiation path in the transverse direction, and a high optical Q for the transverse escape mode is thus realized. In this manner, coherent emission over a much larger area can be obtained in the inventive laser than with presently known laser structures.

There has been described herein a novel solid state radiation emitter device that affords increased efficiency of coherent radiation over a wide area of emission. The radiation output may be obtained in the direction of current flow or orthogonal to such direction. Furthermore, the structure may be formed from common semiconductor materials, characterized by an indirect energy gap, as well as from those materials having a direct energy gap. In addition, the inventive light radiating device can be operated at ambient temperatures and requires only a low electrical power input for activation.

It should be noted that the structures, materials, and conditions and parameters set forth above are only illustrative, and that the scope of the invention is not necessarily limited thereto. Therefore, the invention encompasses various alternatives that may be utilized successfully in light of the teachings herein.

What is claimed is:

1. A heterojunction solid state optical frequency radiation device including at least two different types of semiconductor materials united together to form a heterojunction semiconductor body, one of said at least two different types of semiconductor materials forming an injector region and the other of said at least two different types of semiconductor materials forming a base region, said injector region including semiconductor injector regions disposed on opposite sides of said base region, said semiconductor injector regions having opposite types of conductivity relative to each other, said semiconductor material forming said injector regions having a larger forbidden band gap than said semiconductor material forming said base region, said semiconductor injector regions having higher doping levels than said base region, said injector and base regions being physically inter-related relative to each other and provided with bias means for injecting carriers from said injector regions into said base region such that carrier accumulation in said base region exceeds levels in excess of the doping levels of said injector regions while inhibiting carrier run-off from said base region into said injector regions.

2. The solid state radiation device defined in claim **1**, wherein at least one of the semiconductors is an element found in Group IV of the Periodic Table.

3. The solid state radiation device defined in claim **1**, wherein at least one of the semiconductors is formed from compounds of elements found in Groups III and V of the Periodic Table.

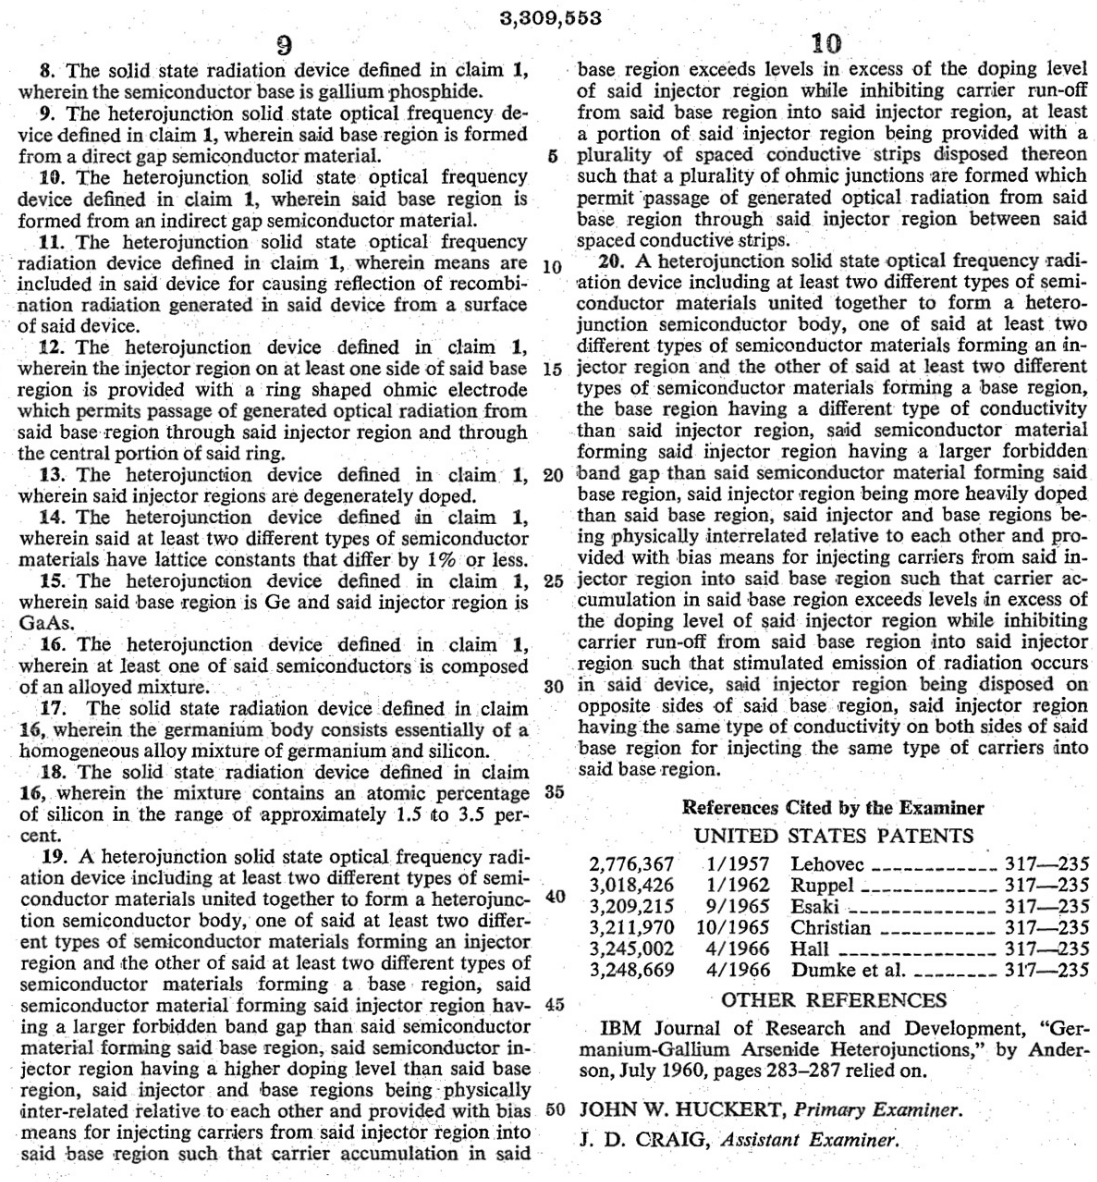
4. The solid state radiation device defined in claim **1**, wherein at least one of the semiconductors are formed from compounds of elements found in Groups II and VI of the Periodic Table.

5. The solid state radiation device defined in claim **1**, wherein at least one of the semiconductors is selected from the class that crystallizes in the zincblende lattice.

6. The solid state radiation device defined in claim **1**, wherein at least one of the semiconductors is selected from the class that crystallizes in the diamond lattice.

7. The solid state radiation device defined in claim **1**, wherein at least one of the semiconductors is formed from a homogeneous alloy mixture of at least semiconductors.

Figure B.241: Herbert Kroemer invented the double-heterostructure laser diode in 1963.



8. The solid state radiation device defined in claim **1**, wherein the semiconductor base is gallium phosphide.

9. The heterojunction solid state optical frequency device defined in claim **1**, wherein said base region is formed from a direct gap semiconductor material.

10. The heterojunction solid state optical frequency device defined in claim **1**, wherein said base region is formed from an indirect gap semiconductor material.

11. The heterojunction solid state optical frequency radiation device defined in claim **1**, wherein means are included in said device for causing reflection of recombination radiation generated in said device from a surface of said device.

12. The heterojunction device defined in claim **1**, wherein the injector region on at least one side of said base region is provided with a ring shaped ohmic electrode which permits passage of generated optical radiation from said base region through said injector region and through the central portion of said ring.

13. The heterojunction device defined in claim **1**, wherein said injector regions are degenerately doped.

14. The heterojunction device defined in claim **1**, wherein said at least two different types of semiconductor materials have lattice constants that differ by 1% or less.

15. The heterojunction device defined in claim **1**, wherein said base region is Ge and said injector region is GaAs.

16. The heterojunction device defined in claim **1**, wherein at least one of said semiconductors is composed of an alloyed mixture.

17. The solid state radiation device defined in claim **16**, wherein the germanium body consists essentially of a homogeneous alloy mixture of germanium and silicon.

18. The solid state radiation device defined in claim **16**, wherein the mixture contains an atomic percentage of silicon in the range of approximately 1.5 to 3.5 percent.

19. A heterojunction solid state optical frequency radiation device including at least two different types of semiconductor materials united together to form a heterojunction semiconductor body, one of said at least two different types of semiconductor materials forming an injector region and the other of said at least two different types of semiconductor materials forming a base region, said semiconductor material forming said injector region having a larger forbidden band gap than said semiconductor material forming said base region, said semiconductor injector region having a higher doping level than said base region, said injector and base regions being physically inter-related relative to each other and provided with bias means for injecting carriers from said injector region into said base region such that carrier accumulation in said base region exceeds levels in excess of the doping level of said injector region while inhibiting carrier run-off from said base region into said injector region, at least a portion of said injector region being provided with a plurality of spaced conductive strips disposed thereon such that a plurality of ohmic junctions are formed which permit passage of generated optical radiation from said base region through said injector region between said spaced conductive strips.

20. A heterojunction solid state optical frequency radiation device including at least two different types of semiconductor materials united together to form a heterojunction semiconductor body, one of said at least two different types of semiconductor materials forming an injector region and the other of said at least two different types of semiconductor materials forming a base region, the base region having a different type of conductivity than said injector region, said semiconductor material forming said injector region having a larger forbidden band gap than said semiconductor material forming said base region, said injector region being more heavily doped than said base region, said injector and base regions being physically interrelated relative to each other and provided with bias means for injecting carriers from said injector region into said base region such that carrier accumulation in said base region exceeds levels in excess of the doping level of said injector region while inhibiting carrier run-off from said base region into said injector region such that stimulated emission of radiation occurs in said device, said injector region being disposed on opposite sides of said base region, said injector region having the same type of conductivity on both sides of said base region for injecting the same type of carriers into said base region.

B.5 Postwar Transfer of Microelectronics Technologies

[Detailed technical information on semiconductors and microelectronics technologies was transferred from the German-speaking world to Allied countries after World War II. Some examples have already been mentioned earlier in this appendix. Pages 2926–3013 present additional examples of archival documents demonstrating the postwar transfer of microelectronics documents, hardware, personnel, and knowledge. There was likely a great deal of additional technology transfer that was not recorded in official documents.

The financially and politically powerful combined corporate entity American Telephone & Telegraph (AT&T), Bell Telephone Laboratories (Bell Labs), and Western Electric (the manufacturing arm of the corporation) committed a number of its personnel to studying technology from the German-speaking world, both collecting information in Europe and analyzing information that had been sent from Europe to the United States. While certainly not an exhaustive list, some representative examples of involved personnel include:

- Edwin Y. Webb Jr. worked for AT&T 1928–1944 before entering government service during the war. He was Chief in charge of investigating and transferring electronics and communications-related technologies out of the German-speaking world for the United States.
- George Richert worked for Bell Telephone 1927–1942 before entering government service during the war. He was Assistant Chief in charge of investigating and transferring electronics and communications-related technologies out of the German-speaking world for the United States.
- T. M. Odarenko worked for Bell Telephone 1928–1943 before entering government service during the war. He was one of the senior U.S. scientists involved in investigating and transferring electronics and other technologies out of Germany and Austria.
- Pierre Mertz worked at Bell Labs and visited Germany to transfer electronics and related technologies.
- Frederick E. Henderson worked at Western Electric and visited Germany to transfer electronics and related technologies.
- Roland H. McCarthy worked at Western Electric and visited Germany to transfer electronics and related technologies.
- John A. Parrott worked at AT&T and visited Germany to transfer electronics and related technologies.
- R. E. Russell worked at AT&T and visited Germany to transfer electronics and related technologies.
- John R. Townsend worked at Bell Labs and studied German hardware and information both in Europe and at Bell.
- Victor Ronci worked at Bell Labs developing improved versions of vacuum tubes, and was involved in analyzing captured German hardware and information that was sent to Bell Labs.

- Lloyd Espenschied worked at Bell Labs to study captured German hardware and information that was sent to the lab.
- John N. Shive worked at Bell Labs to study captured German hardware and information that was sent to the lab.
- F. A. Cowan worked at AT&T and advised the U.S. government what specific targets and topics to investigate with regard to wire communications systems.
- George W. Gilman worked at Bell Labs and advised the U.S. government what specific targets and topics to investigate with regard to radio communications systems.
- R. E. Poole worked at Bell Labs and advised the U.S. government what specific targets and topics to investigate with regard to radar systems.
- W. H. Martin worked at Bell Labs and advised the U.S. government what specific targets and topics to investigate with regard to "special systems."
- Julian Blanchard was assigned by AT&T/Bell/Western Electric to work full time in Washington, D.C. during 1946–1947 searching the many tons of captured German reports for any useful information he could send to the corporation.
- Both William Shockley and John Bardeen of Bell Labs visited laboratories in several European countries during a research trip from June through August 1947. During that time, Shockley or Bardeen may have encountered scientists, reports, or information from the earlier transistor work that had been conducted in the German-speaking world. Alternatively they might have encountered Allied investigators who had already examined that work and could pass along useful information. Shockley and Bardeen's transistor experiments at Bell Labs were entirely unsuccessful during the long period before their European trip, and extremely successful very shortly after their trip [Hoddeson and Daitch 2002, pp. 128–131].

Other American and British electronics and other companies also committed large numbers of investigators to study and bring back technologies from the German-speaking world.

Many English-language reports were written about German microelectronics technologies. Some examples include:

BIOS 724. *Electronic Principles as Applied in Germany to the Testing of Materials.* [Piezo-electric, electronic materials testing]

BIOS 725. *German Research on Rectifiers and Semi-Conductors.*

BIOS 980. *Electro-Acoustics in Germany. Part I & II.*

BIOS 1751. *German Research on Semi-Conductors, Metal Rectifiers, Detectors and Photocells.*

FIAT 54. *German Developments in Semi-Conducting Materials.* [by T. M. Odarenko]

FIAT 56. *Selenium Rectifier Development in Germany.* [by T. M. Odarenko]

> FIAT 272. *Telefunken A.G. Dachau, Germany and C. H. F. Mueller A.G. Fuhlsbuettel, Hamburg.* [Silicon crystals]
>
> FIAT 294. *Interrogation of German Television and Electronic Authorities.* [Electronics developments, photoelectric, IR image tubes, silicon detector cells]
>
> FIAT 641. *The Interrogation of German Scientists Regarding Quartz Crystals and other Piezoelectric Materials.*
>
> FIAT 706. *Report on Selenium Dry Rectifier Developments.*
>
> FIAT 954. *A Highly Sensitive D.C. Controlling & Measuring Device.* [Amplifier]

For example, BIOS 725 described how German groups were making wafers of monocrystalline pure silicon, doping semiconductor materials with impurities to create the desired electrical properties, and producing semiconductor devices both from silicon and from germanium:

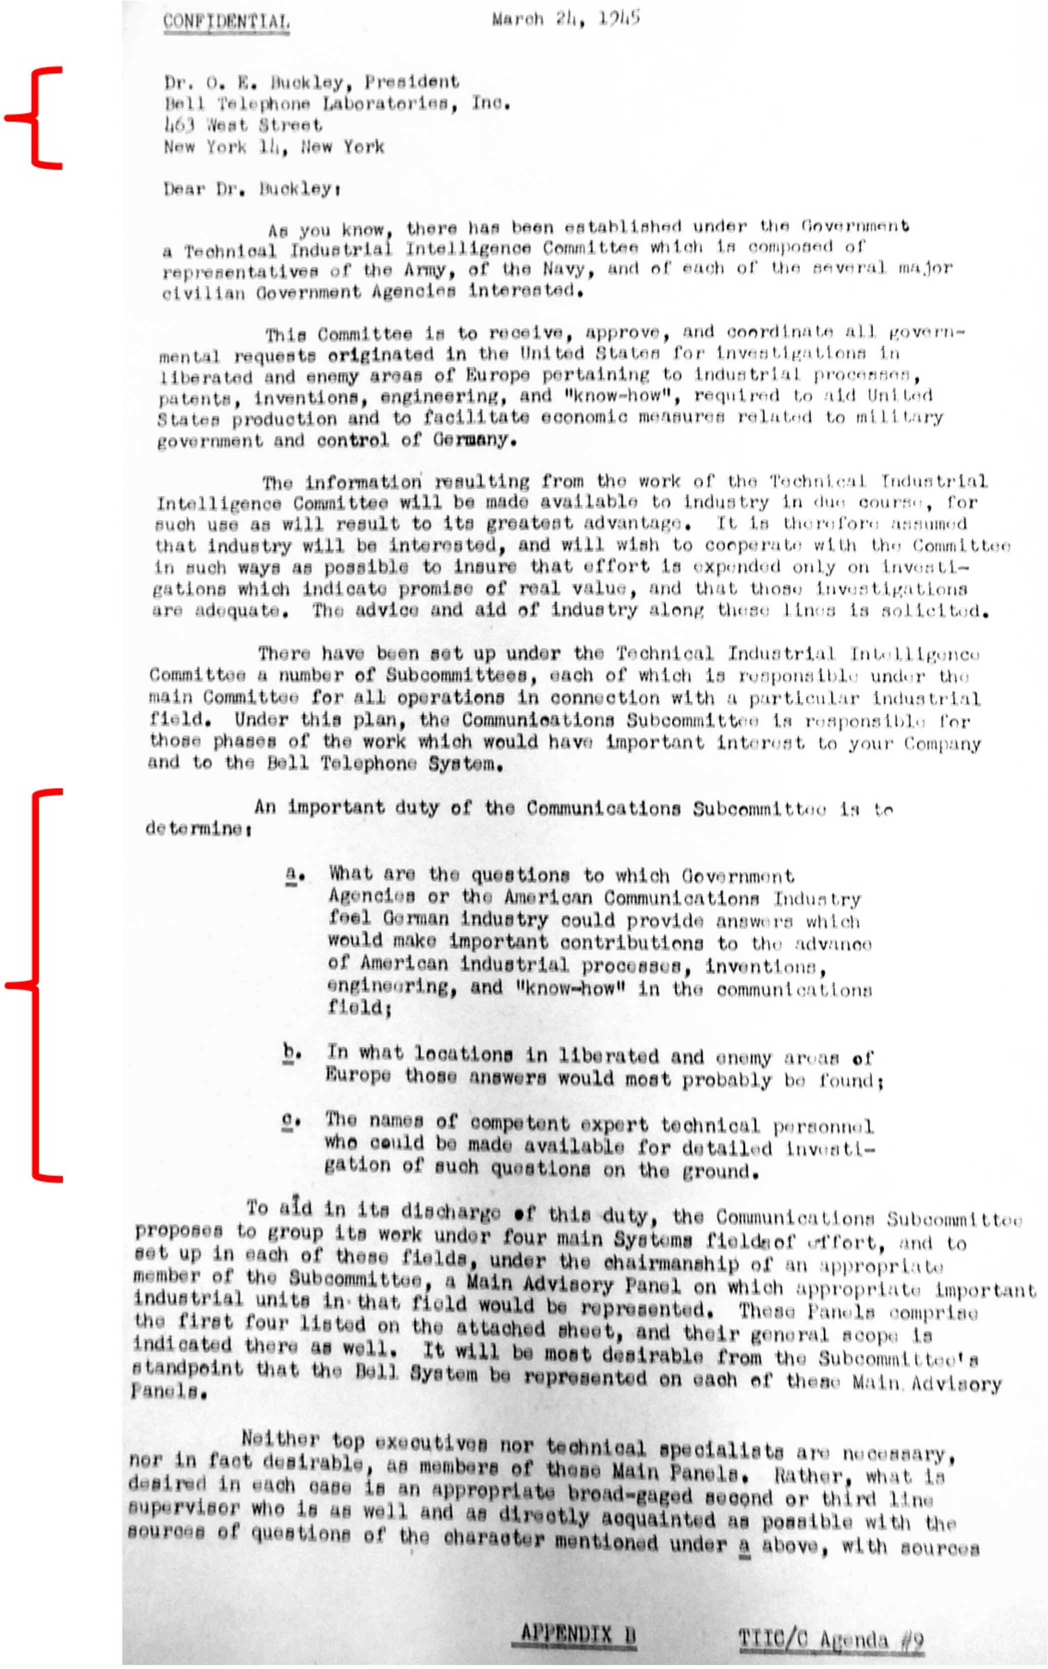
> Impurities in a semi-conductor produce additional energy-levels; perhaps a pure material could not be a semi-conductor. There must be some broadening of the energy levels into bands... Joos tried to produce large crystals of silicon for use in silicon-carbon detectors for cm. waves. The method was deposition from a solution of silicon in molten aluminum. The crystals so obtained were spectroscopically pure... They were aggregations of thin plates... Prof. Pohl confirmed that Dr. König had studied germanium and silicon rectifiers at Göttingen...

Countless tons of both electronics equipment and German technical documents were shipped to the United States and other countries.

German-speaking scientists were repeatedly interrogated in Europe, and/or brought to the United States or other countries to work, as covered in Chapter 11. For example, Hans K. Ziegler (German, 1911–1999) came to the United States in Operation Paperclip. He became the Chief Scientist of a U.S. Army laboratory in Fort Monmouth, New Jersey, that employed many other German-speaking scientists and harnessed many microelectronics technologies acquired from Germany, Austria, and Czech territory [Fort Monmouth Historical Office 2008]. See pp. 1153–1154, 2760, and 3013. Many other German-speaking scientists were hired by other U.S. laboratories or companies.

On top of all of the technology transfer that was documented to have occurred, it seems likely that there was a considerable amount of additional technology transfer that was not recorded in official documents. The German-speaking world was filled with advanced technologies, and it would have been a great temptation for any Allied investigator or company to try to claim some of those technologies in order to get ahead of their rivals. Thus the innovations from the German-speaking world probably had a much greater postwar impact on the United States and other countries than can be strictly proven from the existing archival documents.]

DECLASSIFIED
Authority NND 968018



CONFIDENTIAL March 24, 1945

Dr. O. E. Buckley, President
Bell Telephone Laboratories, Inc.
463 West Street
New York 14, New York

Dear Dr. Buckley:

As you know, there has been established under the Government a Technical Industrial Intelligence Committee which is composed of representatives of the Army, of the Navy, and of each of the several major civilian Government Agencies interested.

This Committee is to receive, approve, and coordinate all governmental requests originated in the United States for investigations in liberated and enemy areas of Europe pertaining to industrial processes, patents, inventions, engineering, and "know-how", required to aid United States production and to facilitate economic measures related to military government and control of Germany.

The information resulting from the work of the Technical Industrial Intelligence Committee will be made available to industry in due course, for such use as will result to its greatest advantage. It is therefore assumed that industry will be interested, and will wish to cooperate with the Committee in such ways as possible to insure that effort is expended only on investigations which indicate promise of real value, and that those investigations are adequate. The advice and aid of industry along these lines is solicited.

There have been set up under the Technical Industrial Intelligence Committee a number of Subcommittees, each of which is responsible under the main Committee for all operations in connection with a particular industrial field. Under this plan, the Communications Subcommittee is responsible for those phases of the work which would have important interest to your Company and to the Bell Telephone System.

An important duty of the Communications Subcommittee is to determine:

a. What are the questions to which Government Agencies or the American Communications Industry feel German industry could provide answers which would make important contributions to the advance of American industrial processes, inventions, engineering, and "know-how" in the communications field;

b. In what locations in liberated and enemy areas of Europe those answers would most probably be found;

c. The names of competent expert technical personnel who could be made available for detailed investigation of such questions on the ground.

To aid in its discharge of this duty, the Communications Subcommittee proposes to group its work under four main Systems fields of effort, and to set up in each of these fields, under the chairmanship of an appropriate member of the Subcommittee, a Main Advisory Panel on which appropriate important industrial units in that field would be represented. These Panels comprise the first four listed on the attached sheet, and their general scope is indicated there as well. It will be most desirable from the Subcommittee's standpoint that the Bell System be represented on each of these Main Advisory Panels.

Neither top executives nor technical specialists are necessary, nor in fact desirable, as members of these Main Panels. Rather, what is desired in each case is an appropriate broad-gaged second or third line supervisor who is as well and as directly acquainted as possible with the sources of questions of the character mentioned under a above, with sources

CONFIDENTIAL - 2 -

of information of the character mentioned under b, and with the men both inside and outside your organization who would be competent and who could probably be made available to undertake investigations of the sort contemplated under c. The duties of Main Panel members will be limited to the collection of information of this character, and to its presentation and discussion at half-day meetings in Washington not more frequently than once a month for a period of perhaps six months. Thereafter, it would be expected such meetings would be less frequent.

The following have been suggested as men who, from the point of view of the Communications Subcommittee, would be admirably suited to represent the Bell Telephone System on the four Main Panels:

PANEL I WIRE COMMUNICATIONS SYSTEMS

Mr. George Gillman, B.T.L.

PANEL II RADIO COMMUNICATIONS SYSTEMS

Mr. F. M. Ryan, AT&T Co.

PANEL III RADAR SYSTEMS

Mr. J. R. Wilson, B.T.L., or
Mr. R. E. Poole, B.T.L.

PANEL IV SPECIAL SYSTEMS

Mr. W. H. Martin, B.T.L.

These names will perhaps serve to convey an idea of the character of men we feel could appropriately constitute the Panels.

I am sending a copy of this letter to Mr. Pilliod and I would appreciate it very much if you could consider delegating the Bell Laboratories men listed or appropriate substitutes whom you could spare for this work.

We have also given some consideration to the formation of five additional Panels, - listed as Auxiliary Apparatus Panels on the attached sheet. The Subcommittee feels, however, that such an arrangement would make the whole Panel plan a little unwieldy, and it is not proposing to form these Auxiliary Panels at this time. Rather, it would hope your members on the Main Panels could in turn contact representatives of your organization designated to cover each of the general classes of apparatus listed under these Auxiliary Panels, and could thus place themselves in a position to relay to the Main Systems Panel corresponding information bearing on the several types of Apparatus involved. I shall be very much interested in any comments you may have on this approach to our problem in connection with specific types of apparatus, as well as on the Subcommittee's proposed program as a whole.

You will of course find it necessary to consider and to discuss this whole matter with those whom you may wish to advise you in connection with it. I am required to point out, however, that all matters concerned with the methods of securing and handling intelligence are classified as CONFIDENTIAL by the Armed Services, and I know you will have this in mind in any such discussions.

Yours very truly,

/s/

Leighton H. Peebles
Steering Member
Communications Subcommittee

Technical Industrial Intelligence Committee

May 11, 1945

DIRECTOR, AIR TECHNICAL SERVICE COMMAND

Wright Field

Dayton, Ohio

Dear Sir: Attention: Chief, Aircraft Radio Laboratories, Radio and Radar Subdivision, Engg Div., TSERR2A2

This is in reply to your letter of 4 May 1945 telling of the establishment of the Technical Industrial Intelligence Committee and of the opportunity for industrial organizations to collaborate with this committee to the end that information of technical value may be made available to United States production. Your letter under reply also offers this Company the opportunity to submit through Air Technical Service Command, technical problems to be investigated in liberated or enemy areas of Europe.

At the invitation of Mr. L. H. Peebles, Chairman of the Communications Subcommittee of the Technical Industrial Intelligence Committee, the Bell Telephone System has already designated representatives to the several Panels of the Communications Subcommittee and it had been our intention to clear questions and problems of interest to this Company through these Panel representatives. For information, these Panel representatives are as follows:

PANEL I WIRE COMMUNICATIONS SYSTEMS

Mr. F. A. Cowan, A.T.&T.Co.

PANEL II RADIO COMMUNICATIONS SYSTEMS

Mr. G. W. Gilman, B.T.L.

PANEL III RADAR SYSTEMS

Mr. R. E. Poole, B.T.L.

PANEL IV

Mr. W. H. Martin, B.T.L.

Also at the invitation of the Communications Subcommittee, we have designated two highly qualified representatives of Bell Telephone Laboratories to serve as investigators in liberated or enemy areas of Europe in this connection. It is our understanding that the Communications Subcommittee is processing these representatives through the Foreign Economic Administration for such duties in Europe. Under these circumstances, we feel that the needs of this Company in this matter are already cared for and we are accordingly not planning to take advantage of the opportunity offered by your letter under reply to present technical problems through Air Technical Service Command. We are, however, glad to cooperate with the Technical Industrial Intelligence Committee and shall appreciate receiving any reports of investigations in the communications field that can be made available to industry.

Very truly yours,

(Original Signed by
D. A. Quarles)

Director of
Apparatus Development

TECHNICAL INDUSTRIAL INTELLIGENCE COMMITTEE
COMMUNICATIONS SUBCOMMITTEE
ADVISORY PANEL I - WIRE SYSTEMS AND EQUIPMENT

Agenda for Meeting #2 in Room 2037, Temporary Bldg. "R"
Tuesday, 19 June 1945 at 1400

PANEL MEMBERSHIP:

Mr. L. H. Peebles, Steering Member TIIC/C, Chairman
Lt. Col. E. E. Sullo, TIIC/C
Major H. E. Gove, TIIC/C
Major C. K. Chappuis, TIIC/C
Major F. H. King, TIIC/C (Alternate for Major Chappuis)

Mr. R. E. Smith, International Tel. & Tel. Corp.
(Vice President, International Telephone & Radio Corp.)
Mr. F. B. Bramhall, Western Union Telegraph Co.
Mr. F. A. Cowan, American Tel. & Tel. Co.
Mr. R. M. Kalb, U. S. Independent Tel. Assn. (Ind. Tel. Mfrs.)
(In Charge of Engineering, Kellogg Switchboard & Supply Co.
Mr. D. G. Little, Westinghouse Electric Corp.
Mr. E. G. Fraim, Raytheon Manufacturing Co.

1. MR. PEEBLES

a. Welcome representatives from industry.

b. Thank them for evidence of cooperation already shown.

c. Ask Mr. Edwards to report on progress to date.

2. MR. EDWARDS

a. Investigators Made Available:

International Tel. & Tel. Corp.
Federal Telephone & Radio - Mr. Norman Snyder
Dr. T. M. Odarenko

Western Union Telegraph Co. - Mr. C. H. Cramer

Bell Telephone System
American Tel. & Tel. Co. - Mr. J. A. Parrott
Bell Laboratories - Dr. P. Mertz
- Mr. J. R. Townsend
Western Electric - Mr. R. H. McCarthy
—Mr. F. E. Henderson

b. Examples of Technical Investigators who have been made available to Communications Subcommittee by industry, and who are already overseas or being processed to go overseas:

(1) Dr. P. Mertz - Bell Laboratories
Transmission Expert on facsimile, television, telegraph, broad-band multiplex telephone, etc.

(2) Mr. R. H. McCarthy - Western Electric Co.
Manufacturing planning engineer,-expert on production of telephone central office apparatus and equipment, vacuum tubes, telephone cable and wire, etc.

(3) Mr. C. W. Hansell - Radio Corporation of America
Expert radio circuit and apparatus engineer on telephone, telegraph, facsimile, and television.

(4) Mr. J. A. Parrott - American Telephone & Telegraph Co.
Expert in overall planning, layout, and operation of wire and radio communications plant.

(5) Mr. J. R. Townsend - Bell Laboratories
Expert materials engineer on springs, die castings, plastics, welding, gauging, etc. as applied to design and production of communications apparatus. President-Elect, A.S.T.M.

5. INDUSTRY MEMBERS

Opportunity to present:

a. Position of their companies with respect to above program;

b. Suggested items for CAFT investigators to keep their eyes open for as they center a new geographical area of Germany;

c. Any specific targets which they may have ready;

d. Estimates of number and importance of further targets which they feel they will be able to present at subsequent meetings:

e. Names of competent utility investigators whom their Companies might now be able to make available;

f. Names and specialties of competent expert investigators whom their Companies might now be able to make available;

g. Estimates of number of investigators their Companies might be able to make available at later dates, and approximately when.

Mr. R. Hunt Brown - International Telephone & Telegraph Corp.
Mr. F. B. Bramhall - Western Union Telegraph Co.
Mr. F. A. Cowan - American Telephone & Telegraph Co.
Mr. D. G. Little - Westinghouse Electric & Mfg. Co.
Mr. R. M. Kalb - Kellogg Switchboard & Supply Co. (Representing Independent Telephone Mfrs. of U. S. Independent Telephone Assn.)

6. GENERAL DISCUSSION

7. NEXT MEETING

If industry members indicate they might have more targets or investigators to present at an early date, suggest meeting on Tuesday, 19 June at 2:00 PM, same place.

Otherwise, meeting on call of Chairman.

4. MR. EDWARDS

a. Examples of targets already submitted by industry:

(1) Indiana Steel Products Co. has asked for all available information on composition and processing of permanent magnets, - submitting list of 17 German patents and names of German companies and German personnel for investigation and interrogation.

(2) General Electric Company has asked general and specific questions regarding vacuum tubes, selenium rectifiers, polarized relays, Karbowid resistors, and thermocouples, - giving names of German companies and personnel in some instances.

b. Examples of Technical Investigators who have been made available to Communications Subcommittee by industry, and who are already overseas or being processed to go overseas:

(1) Mr. Norman Snyder, Federal Telephone and Radio Laboratories
Expert on radio, facsimile, television, navigational aids, etc.
Fluent command of German.

(2) Mr. F. E. Henderson, Western Electric Co.
Manufacturing planning engineer,-expert on production of radio transmitters and receivers, field telephone sets, ground and search radars, radar test sets, airplane crew trainers, etc.

(3) Mr. C. W. Mansell, Radio Corporation of America
Expert radio circuit and apparatus engineer on telephone, telegraph, facsimile, and television.

(4) Mr. J. A. Parrott, American Telephone & Telegraph Co.
Expert in overall planning, layout, and operation of wire and radio communications plant.

(5) Mr. J. R. Townsend, Bell Laboratories
Expert materials engineer on springs, die castings, plastics, welding, gauging, etc. as applied to design and production of communications apparatus. President-Elect, A.S.T.M.

5. INDUSTRY MEMBERS

Opportunity to present:

a. Position of their companies with respect to above program;

b. Suggested items for CAFT investigators to keep their eyes open for (as they enter a new geographical area of Germany);

SUBJECT: German High-Frequency Establishments in Russian-Occupied Territory.

Dr. Güllner, the Blaupunkt Company high-frequency expert, who is now working for the Russian army in Berlin, was taken on an inspection tour of German plants in the Russian-occupied zone of Germany. Following is a report about this trip which he submitted to the Alsos Mission:

"During the collapse and the invasion by the Red Army, I was with my family in Guesen near Burg. About ten days after the occupation of Guesen by the Russians, I was ordered to appear at their city headquarters. The town commandant explained that the head of the German Communist Party, Mr. Wricke, had told him that I was a well-known scientist along the lines of war-technology and that I had received the Dr. Fritz Todt Prize. The Red Army was much interested in me and was ready to offer me a suitable position in Moscow. The commandant asked me to report to headquarters every evening. During the course of the following eight days, a large number of Red Army officers came, among them engineers, who talked with me about the fields in which I specialized. Headquarters at Guesen immediately saw to it that my family and I received plentiful extra rations.

"After about eight days, I was again ordered to appear at headquarters. It was explained to me that the Red Army was going to transport me to Berlin where I was to resume activities with my firm for the Red Army. That was at the end of May. However, instead of being transported to Berlin, I was sent to the GPU at Kirchmoeser. Here non-specialists questioned me about six times concerning my activities with the firm of Blaupunkt and had me sign several protocols. These interviews and protocols were totally useless since they were made by non-specialists and contained only superficial data of the Blaupunkt developments. After about two weeks, the GPU section left Kirchmoeser and transferred me to a GPU section at Brandenburg. There several officers asked me the same questions as the ones I had been asked at Kirchmoeser, mostly at night. Upon my suggestion to call in specialists for these interrogations, it was explained to me that that would come later.

"After approximately ten more days, I was awakened at three o'clock one morning and told that I could leave for Berlin the next morning.

"Two days after my arrival in Berlin, several Russian officers called on me. This time they were scientists from Moscow who wanted to be oriented on the development projects of the firm of Blaupunkt. In addition to radar, the gentlemen were particularly interested in remote-control devices, especially

in remote-control devices connected with V 1 and V 2 and with future V-weapons. After this conversation Colonel Schapiro asked me to accompany him on a trip through the Russian-occupied territories; the purpose of the trip was to obtain data from the still-existing plants and engineers about the electrical equipment and control of the V-weapons and of the A 4-program. We started out on the trip a few days later, about the end of June. The party consisted of Colonel Schapiro, Professor of Ballistics at the Military Academy at Moscow, two majors, one of whom was a high-frequency and the other an aerodynamics man, two chauffeurs and myself. A truck and a regular car were at our disposal.

"The following places were visited:

"Sorau: (Telefunken remote-control development)

"Most of the Telefunken plant was empty, inasmuch as engineers had removed machines and other apparatus before the occupation by the Russians. Only some plans for the "Rheinland" system (rocket radio control), particularly about the "Elsass" system were found.

"Sagan:

"In Sagan itself, a state-owned depot (reichseigenes Lager) was visited; a few less important devices FuG 16 etc. were found here.

"Zittau.

"In Zittau, the firm of Seibt was visited. Apparatus "Erstling", receiver for the German recognition system, as well as apparatus "Neptun", a warning device for night fighters, were found. The firm of Seibt had been cleared out only in part and still had large reserves, partly finished apparatus, partly single construction pieces.

"Reichenberg:

"Here the development and the construction plant of the firm of Blaupunkt was visited. The development equipment had been largely removed while the construction plant was still completely intact. Apparatus known as "Erstling" and "Kuh" were found at Blaupunkt. Found also were plans and a sample, also testing apparatus for the "Tonne p", a television head (Fernsehkopf) for gliding bombs (Gleitbombe).

"Tannwald near Gablonz:

"There the Fernseh A.G., a sister firm of Blaupunkt, was visited. This firm was capable of full production; only a few parts had been evacuated before the Russian occupation. Here about 150 research engineers and specialists were still at work. We found nearly all television devices developed in Germany, such as "Tonne", "Sprotte", and the receiver "Seedorf", with full

details. The firm had a Russian commandant, with a Czech officer as an aide. Colonel Schapiro did not take any material from this plant because it was accessible to the Red Army anyway.

"Morchenstern:

"Here we visited the firm Getewent, since television devices and other material were supposed to be stored there. But we only found a few devices such as "Tonne a" of the firm of Blaupunkt and a few television cameras (Fernseh-Kamera) FHK 11 of the Fernseh A.G.

"Hirschberg:

"We visited an evacuation depot of the firm of Askania. The majority of engineers and specialists working there were still present. The plant had not been damaged or evacuated. Plans of standard circuits (Normkreis) used by the German army in V-projectiles were found, as well as plans for automatic pilots, for new automatic optical aiming devices for fighters, for piloting apparatus and, especially important and interesting, for new-type oil pressure motors which served as steering motors in the V-projectiles.

"Glatz (Mittelstein):

"Firm Patin was visited which had supplied parts for the steering-mechanism of the V 1 projectile. The factory was in the process of being evacuated by the Russians; it was to be transported to Russia together with the engineers most of whom had volunteered.

"Brieg and Breslau:

"In neither of these two places did we visit electro-technical or high-frequency plants. Colonel Schapiro visited the firm of Lincke-Hoffmann which had assembled V-projectiles, but he did that without me.

"Originally a continuation of the trip to Prague had been planned; it had to be abandoned, however, when the gasoline supply taken along gave out.

"The whole trip lasted approximately twelve days. The competence of Colonel Schapiro and of the Major in the field of high-frequency technique was considered good. The result of the trip was satisfactory.

"Two days after my return to Berlin about the 10th of July, I was visited by Colonel Schapiro and asked to come to Weissensee, in order to work as a member of his commission on the plans for the remote-control of V-projectiles. About 15 engineers comprised this commission, mostly employees of Telefunken.

"The work rooms of this commission were originally at Zehlendorf. A few hours prior to the occupation by the Americans, they were transferred to

Weissensee. The engineers themselves were living in villas which had been vacated on short notice and were well taken care of. As remuneration, their old salaries were promised to them. This commission was mainly reconstructing the "Rheinland" system and was collecting basic information. From Blaupunkt two more gentlemen besides myself were working in the commission.

CONFIDENTIAL

"The firm of Blaupunkt is to supply material for homing devices, television heads (Fernsehkopf), proximity fuzes, etc.

"A few days later, I was asked to accompany Colonel Schapiro on a trip to Belzig, Burg and Rathenow. This trip lasted for about four days.

"At the end of July, Blaupunkt was visited by a commission, with Colonels Schapiro and Gromow present; the following was agreed upon.

"1) Blaupunkt is to reconstruct the plans of all its developments of a peaceful nature, particularly radio and television sets, and of all its war developments. For this purpose a commission under my chairmanship is to be created, to consist, at first, of approximately 50 persons. On the basis of these plans, the Red Army will give orders to Blaupunkt.

"2) Blaupunkt is immediately to reopen its development section of approximately 200 persons, in order to produce samples.

"The plant is to be at Treptow, in the Russian zone of occupation.

"The Red Army is to undertake temporarily the payment of the employees at the old rates. Later the payment is again to be made by the firm itself.

"This action which the Red Army took with respect to Blaupunkt has also been taken with other firms such as Kreisel G.m.b.H., Askania. Upon orders from Moscow the Russians have also started an Institute for High-Frequency Technique, especially for the development of tubes; it is headed by the well-known German tube expert, Dr. Steimel of Telefunken. Up to 1800 persons are said to be working for this Institute, including 300 Russian engineers who are replaced by new ones every few years. Russian engineers also are to be active in the Blaupunkt works and are to be replaced from time to time. Problems in the Institute of Dr. Steimel are mainly those of tube technique and of high-frequency technique in the cm region.

"For purposes of liaison, a Major Gurewitsch is working at Blaupunkt. It is continuously being stressed that the Russians want apparatus primarily for peace purposes. On the other hand, however, they are also very much interested in homing devices and proximity fuzes.

"Dr. Guellner said the following about his personal impressions of the abilities of the Russians along the lines of organization and technique:

"The officers with whom I had dealings had very little freedom of action; they received their orders directly from Moscow. Their capabilities are consistently good; the same holds for their scientific knowledge except that they do not have practical minds, with the result that they have no ability when it comes to construction and fabrication.

"The knowledge of the Russians in high-frequency technique, especially remote-control, measuring techniques and cm-technique is generally very slight, since they have not worked on these problems to any great extent.

"Except for these officers who belonged to the very thin layer of intelligentsia, I have the worst possible opinion of the Russians with regard to their ability for organization and their mental capacity. Sufficient organization simply does not exist. Most bureaus work parallel without regard to one another. So, e.g., it is impossible for Blaupunkt to get some of its important apparatus returned which the evacuation-commission had transported to the railway station at Rummelsburg, even though Colonel Schapiro had manifested a very great interest in it and even though it would be easily obtainable at the station.

"All basic developments must be done over again, causing much difficult work and permitting only partial completion.

"A man with a good knowledge of new Russia explained to me that, if a Russian wants to repair his bicycle, he will take his automobile apart in order to get spare parts, even though he knows that he will need his automobile in a few days."

S. A. GOUDSMIT
Scientific Chief

Figure B.254: Account from a German electrical engineer regarding some former German advanced electronics facilities that were now in Soviet-controlled territory [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL].

Klaus-Dietmar Henke. 2015. *Die amerikanische Besetzung Deutschlands.* 2nd ed. Berlin: De Gruyter. pp. 754–758. https://books.google.com/books?id=J73yCQAAQBAJ

Ebenfalls im Mai hatte sich, wie gezeigt, in der Truman-Administration trotz der massiven Einwände Churchills die übereinstimmende Auffassung herauskristallisiert, die amerikanischen Truppen müßten auf jeden Fall in Kürze aus der künftigen sowjetischen Besatzungszone in Mitteldeutschland abgezogen werden. Von Mitte Juni datiert das Telegramm, in dem der amerikanische Präsident dies Stalin mitteilte.[310] Entsprechend zielstrebig ging die Army in Mitteldeutschland vor. Am 25. Mai erfolgte die Weisung an das Ordnance Technical Intelligence Team im Harz, die dortigen Spezialisten samt ihren Familien so weit nach Westen wegzuführen, daß sie mit Sicherheit unter amerikanischer Kontrolle bleiben würden.[311] Bald darauf korrespondierten Eisenhower und Marshall über die Lage im Raum Nordhausen, die Phantasie und Energie der T-Forces so gefangennahm. Dabei verwies der Oberbefehlshaber darauf, daß die Intelligence Teams ihre Arbeit in den unterirdischen Produktionsstätten für Raketen nirgends auch nur annähernd abgeschlossen hätten.[312] Obwohl Eisenhower es nicht erwähnte, galt diese Feststellung natürlich erst recht für die übrigen wissenschaftlich-technischen Objekte in Sachsen und Thüringen, die ebenfalls kriegswichtig, aber weniger spektakulär und deshalb nicht alle von Anfang an mit demselben Nachdruck ausgeforscht worden waren.

Also in May, as shown, the consensus view had emerged in the Truman administration, despite Churchill's massive objections, that American troops would have to be withdrawn from the future Soviet occupation zone in central Germany in any case in the near future. The telegram in which the American president communicated this to Stalin dates from mid-June.[310] The Army proceeded with corresponding determination in central Germany. On May 25, instructions were given to the Ordnance Technical Intelligence team in the Harz Mountains to move the specialists there, together with their families, so far west that they would certainly remain under American control.[311] Soon thereafter, Eisenhower and Marshall corresponded about the situation in the Nordhausen area, which so captured the imagination and energy of the T-Forces. In doing so, the commander in chief pointed out that the intelligence teams had nowhere even remotely completed their work in the underground production facilities for rockets.[312] Although Eisenhower did not mention it, this observation naturally applied a fortiori to the other scientific and technical facilities in Saxony and Thuringia, which were also important to the war effort but less spectacular and therefore had not all been explored with the same vigor from the beginning.

[310] Cf. Eisenhower Papers, VI/4.

[311] Lasby, Paperclip, p. 43.

[312] Eisenhower's telegram to Marshall v. 7. 6. 1945; Eisenhower Papers, VI, p. 143 ff.

Dieser ärgerliche Umstand mag Eisenhower zwei Tage zuvor besonders schmerzlich bewußt geworden sein, als beim ersten Zusammentreffen der Militärgouverneure in Berlin in aller wünschenswerten Klarheit herauskam, daß die Räumung der sowjetischen Besatzungszone unmöglich noch länger hinausgeschoben werden konnte. Das steigerte die Hektik der allierten T-Forces noch, deren detektivisch-kriminalistische Arbeit überall, aber besonders in Mitteldeutschland, unter einem beträchtlichen Zeit- und Konkurrenzdruck durchgeführt werden mußte. Im Juni steigerte sich die Hektik der Intelligence Teams, die in den überaus ergiebigen, bald zu übergebenden Gebieten noch längst nicht alles unter Dach und Fach hatten, zu kopfloser Hast. Unmittelbar nachdem Truman den britischen Premierminister und Stalin von dem bevorstehenden Rückzug seiner Truppen in Kenntnis gesetzt hatte, erließ das Allierte Oberkommando in Einklang mit der militärischen Führung in Washington am 18. und 19. Juni 1945 die streng geheimen Befehle, beim Abzug alle jene deutschen Wissenschaftler und Techniker zu "evakuieren", deren Fähigkeiten und Kenntnisse Großbritannien und die Vereinigten Staaten nutzen wollten.[313]

Eisenhower may have become particularly painfully aware of this annoying circumstance two days earlier when, at the first meeting of the military governors in Berlin, it emerged with all desirable clarity that the evacuation of the Soviet occupied zone could not possibly be postponed any longer. This increased the hectic pace of the Allied T-Forces, whose detective-criminal work had to be carried out everywhere, but especially in central Germany, under considerable time and competitive pressure. In June, the hectic pace of the intelligence teams, who were far from having everything under control in the extremely productive areas soon to be handed over, increased to headlong haste. Immediately after Truman notified the British prime minister and Stalin of the impending withdrawal of his forces, the Allied High Command, in concert with the military leadership in Washington, issued top-secret orders on 18 and 19 June 1945 to "evacuate" on withdrawal all those German scientists and technicians whose skills and knowledge Britain and the United States wished to use.[313]

---

[313] Die Daten dieser Befehle (SHAEF, GBI/FIAT/322-21/1) gehen aus einem Schreiben des Chefs von FIAT an den Kommandierenden General von USFET, ACOS G-5, v. 16. 7. 1945 hervor ("Evacuation of German Scientists from Area now under Russian Occupation"); NA, RG 260, 17/11-1. Gimbel, U.S. and German Scientists, S. 438, nennt als Datum des Befchls den 15. Juni.

[313] The dates of these orders (SHAEF, GBI/FIAT/322-21/1) come from a letter from the chief of FIAT to the commanding general of USFET, ACOS G-5, v. 16 July 1945 ("Evacuation of German Scientists from Area now under Russian Occupation"); NARA, RG 260, 17/11-1. Gimbel, U.S. and German Scientists, p. 438, gives the date of the order as 15 June.

Es begann, was ein Offizier der Air Force als “Griff in die russische Zone” titulierte.[314] Zum zentralen Streitpunkt zwischen den USA und der Sowjetunion sollte bald die Frage werden, ob dabei Gewalt angewandt worden sei oder nicht. Obwohl die Amerikaner dies immer entrüstet abstritten, beharrten die Russen völlig zu Recht darauf, daß es keine einfache Evakuierung, sondern eine Zwangsevakuierung gewesen sei, die die U.S. Army bei ihrem Abzug aus Sachsen und Thüringen in Szene gesetzt habe. Tatsächlich gab es kaum eine Fabrik von technologischer Bedeutung, kaum ein naturwissenschaftliches Institut, das die Amerikaner vor ihrem Abrücken aus Mitteldeutschland nicht durchkämmt hätten, auch kaum einen Experten von Rang, den das CIC und die T-Forces in den beiden letzten Juniwochen nicht zur Abreise in den Westen aufgefordert, gedrängt, genötigt oder gezwungen hätten.

There began what one Air Force officer dubbed a “reach into the Russian zone.”[314] The central point of contention between the United States and the Soviet Union would soon become whether or not force had been used in the process. Although the Americans always indignantly denied this, the Russians quite rightly insisted that it was not a simple evacuation but a forced evacuation that the U.S. Army had staged during its withdrawal from Saxony and Thuringia. In fact, there was hardly a factory of technological importance, hardly a scientific institute that the Americans had not combed before their departure from central Germany, and hardly an expert of rank whom the CIC and the T-Forces had not asked, urged, coerced or forced to leave for the West in the last two weeks of June.

---

[314] Lasby, Paperclip, S. 29.

[314] Lasby, Paperclip, p. 29.

Bei Siemens & Halske im thüringischen Arnstadt wurde es am 21. Juni ernst.[315] Am Abend dieses Tages suchten zwei amerikanische Offiziere der 102nd Infantry Division Direktor Lohse in seiner Privatwohnung auf, stellen ihm zunächst einige allgemeine Fragen zur Firmenorganisation, zu den führenden Persönlichkeiten der mitteldeutschen Elektroindustrie (über die sie offenbar Dossiers hatten) und lenkten dann auf den Siemens-Anteil an der V-Waffenproduktion über. Seine Firma habe bestimmte elektrotechnische Bauelemente zugeliefert, erläuterte der für die thüringischen Fabriken bevollmächtigle Siemens-Manager, der nicht zum ersten Mal einer allierten Expertenkommission Rede und Antwort stehen mußte. Doch dann machten ihm die beiden Offiziere einige höchst überraschende Eröffnungen: “Das amerikanische Hauptquartier beabsichtige, im Westen oder Südwesten, jedenfalls nicht in Thüringen, eine Fabrik, die unsere Fertigungen umfassen solle, aufzuziehen”, beschrieb Lohse einige Monate später diese Unterredung. Der endgültige Standort sei ihnen selbst nicht bekannt, sagten die beiden Amerikaner weiter: “Die Fabrik gehöre zunächst keineswegs mehr zu Siemens, sondern unterstände unmittelbar dem Hauptquartier. Es würde aber denkbar sein, daß nach einer gewissen Zeit Fühlungnahme mit den westlichen Siemens-Fabriken möglich sei.”[316]

At Siemens & Halske in Arnstadt, Thuringia, things got serious on June 21.[315] On the evening of that day, two American officers of the 102nd Infantry Division visited Director Lohse in his private apartment, first asked him some general questions about the company’s organization, about the leading figures in the Central German electrical industry (about whom they apparently had dossiers), and then turned their attention to Siemens’ share in the production of V weapons. His company had supplied certain electrotechnical components, explained the Siemens manager authorized for the Thuringian factories, who had not for the first time had to answer the questions of an Allied expert commission. But then the two officers made some highly surprising revelations to him: “The American headquarters intends to set up a factory in the west or southwest, at any rate not in Thuringia, which is to include our production facilities,” Lohse described this conversation a few months later. The final location was not known to them themselves, the two Americans went on to say: “The factory would initially no longer belong to Siemens at all, but would be under the direct control of headquarters. It would be conceivable, however, that after a certain period of time, contact could be made with the Siemens factories in the West.”[316]

---

[315] Zur Situation dieses Zweigbetriebes in den Monaten zuvor vgl. VI/4.

[316] “Persönlicher Bericht über die Zeit von Ende März 1945 bis Ende November 1945” (mit Nachträgen von Anfang 1946), verfaßt von Direktor Adolf Lohse in Erlangen am 21. 11. 1945, dessen Richtigkeit von vier seiner leitenden Mitarbeiter durch Unterschrift bestätigt war; Siemens-Archiv, S AA 11.43/Lm 394, von Witzleben.

[315] For the situation of this branch in the months before, see VI/4.

[316] “Personal report on the period from the end of March 1945 to the end of November 1945” (with addenda from the beginning of 1946), written by Director Adolf Lohse in Erlangen on 21 Nov. 1945, the accuracy of which was confirmed by signature of four of his senior staff; Siemens Archives, S AA 11.43/Lm 394, von Witzleben.

Das war starker Tobak, der dem ahnungslosen Siemens-Direktor, welcher eben die Pläne für die Neuorganisation der mitteldeutschen Konzernbetriebe fertig hatte, mit dieser schon auf den ersten Blick ziemlich unglaubhaft klingenden Mitteilung verabreicht wurde. Er erkundigte sich deshalb auch sofort bei seinen Gästen, ob die Spitzenkräfte der thüringischen Betriebe freiwillig oder zwangsweise an den neuen Standort übersiedeln sollten. Lohse war natürlich vom ersten Augenblick an klar, daß ein für das Firmenschicksal derart einschneidender Schritt unmöglich von einem Tag auf den anderen und keinesfalls ohne Abstimmung zumindest mit Ernst von Siemens in München getan werden konnte. Seine beiden späten Besucher beeilten sich zwar zu beteuern, daß es sich "selbstverständlich" um eine freiwillige Ubersiedlung handele, andererseits verlangten die Offiziere aber "kategorisch", daß "die betr. Siemens-Herren ihre Familien an den fraglichen Ort mitnehmen müßten und daß der Abtransport binnen 48 Std. zu erfolgen habe". Schmackhaft gemacht wurde dieses Ultimatum durch das Versprechen, es stünden für die Familien "völlig eingerichtete Wohnungen" zur Verfügung, für Ernährung, Bekleidung und Erziehung der Kinder sorge das Hauptquartier.

"Als ich den Zusagen gegenüber leichte Zweifel äußerte", hielt der Direktor in seinem Rechenschaftsbericht später fest, "antwortete Mr. Ernest sehr empört, daß ich bedenken möge, daß noch nie eine deutsche Regierung ein derartig faires Angebot an Angehörige eines besiegten Volkes gemacht habe. Ich möchte in dieser Beziehung mich doch insbesondere an die Konzentrationslager, die sie auch in Thüringen vorgefunden hätten, rinnern." Direktor Lohse bekam Zeit bis 8.30 Uhr am nächsten Morgen, um die Mitarbeiter zu benennen, die ihn begleiten sollten. Auch sein Hinweis, er sei Kaufmann und kein Techniker und komme deshalb selbst wohl nicht für den geplanten Abtransport in Frage, fruchtete nichts. Das sei ihnen bekannt, verabschiedeten sich die beiden Offiziere, aber aufgrund ihrer Informationen über seine Person müßten sie Wert darauf legen, daß er den "vom Hauptquartier gewünschten Betrieb unbedingt selbst in die Hand nähme".

This was strong stuff, which the unsuspecting Siemens director, who had just finished the plans for the reorganization of the central German group companies, was presented with this announcement, which sounded quite unbelievable even at first glance. He therefore immediately inquired of his guests whether the top employees of the Thuringian plants were to move to the new location voluntarily or forcibly. Of course, it was clear to Lohse from the very first moment that such a drastic step for the fate of the company could not possibly be taken from one day to the next and under no circumstances without at least consulting Ernst von Siemens in Munich. His two late visitors hastened to affirm that it was "of course" a voluntary resettlement, but on the other hand the officers demanded "categorically" that "the Siemens men concerned must take their families with them to the place in question and that the removal must take place within 48 hours." This ultimatum was made palatable by the promise that "completely furnished apartments" would be available for the families, and that the headquarters would provide food, clothing, and education for the children.

"When I expressed slight doubts about the promises," the director later stated in his report, "Mr. Ernest replied very indignantly that I should remember that no German government had ever made such a fair offer to members of a defeated people. In this respect, I would like to recall in particular the concentration camps which they had also found in Thuringia." Director Lohse was given until 8:30 the next morning to name the staff members who were to accompany him. His comment that he was a merchant and not a technician, and that he himself was therefore probably not eligible for the planned removal, was of no avail. They were aware of this, the two officers said, but on the basis of the information they had about him, they would have to insist that he take the operation "desired by headquarters into his own hands."

Noch in derselben Nacht versammelte Lohse maßgebliche Kollegen um sich und beriet mit ihnen die Lage. Mit einer Reihe seiner engsten Mitarbeiter hatte er in den vorangegangenen Tagen schon wiederholt über die bevorstehende sowjetische Besetzung gesprochen, wobei sie sich einig gewesen waren, bis zur möglichen Liquidierung der Siemens-Betriebe durch die neue Besatzungsmacht auf jeden Fall in Thüringen zu bleiben. An diesem Entschluß änderte zunächst auch die amerikanische Aufforderung zur Übersiedlung in den Westen nichts, zumal sich in der nächtlichen Beratung zeigte, daß eine Reihe von Siemens-Mitarbeitern bereit waren, “mit ihren Familien dem Angebot der amerikanischen Regierung zu folgen”. Andere leitende Angestellte dachten ebenso wie Lohse gar nicht daran, auf die Vorschläge der Besatzungsmacht einzugehen.

Als der Morgen des 22. Juni kam, mußte die Siemens-Spitze in Arnstadt feststellen, daß sie überhaupt keine Entscheidungsfreiheit besaß. Die Amerikaner lehnten die vorbereitete Liste von Ersatzleuten, die bereit waren, mit ihnen abzurücken und die besagte neue Fabrik im Westen aufzubauen, glatt ab. “Mr. Ernest nahm kaum Kenntnis von dieser Aufstellung”, so beschreibt Direktor Lohse die Konfrontation mit der Besatzungsmacht, “sondern erklärte in ziemlich steifem Ton, daß er diese meine Stellungnahme erwartet habe nach der ganzen hinhaltenden Besprechung am Abend zuvor. Die Herren hätten inzwischen mit dem Hauptquartier telefonisch gesprochen und müßten mir nunmehr eröffnen, *daß von einer freiwilligen Abreise nicht die Rede sein könne*, sondern auch die Herren, die in Thüringen bleiben wollten, mit ihren Familien sich schnellstens zum Abtransport fertig zu machen hätten.”[317] Lohse und die übrigen maßgeblichen Siemens-Mitarbeiter, hinter denen die Amerikaner her waren, erkannten jetzt, da weitere Debatten sinnlos waren.

That same night, Lohse gathered senior colleagues around him and discussed the situation with them. In the preceding days, he had repeatedly discussed the impending Soviet occupation with a number of his closest coworkers, and they had agreed to remain in Thuringia in any case until the possible liquidation of the Siemens plants by the new occupying power. Initially, the American request to relocate to the West did not change this decision, especially since it became apparent during the nighttime meeting that a number of Siemens employees were prepared to “follow the American government’s offer with their families.” Other senior executives, like Lohse, did not even think of responding to the occupation forces’ proposals.

When the morning of 22 June came, the Siemens top management in Arnstadt had to realize that they had no freedom of decision at all. The Americans flatly rejected the prepared list of replacements who were willing to leave with them and build the new factory in question in the West. “Mr. Ernest hardly took any notice of this list,” is how Director Lohse describes the confrontation with the occupation forces, “but explained in a rather stiff tone that he had expected this statement of mine after the whole stalling meeting the night before. In the meantime, the gentlemen had spoken to headquarters by telephone and would now have to inform me *that there could be no question of a voluntary departure*, but that the gentlemen who wanted to stay in Thuringia would have to get ready for departure with their families as soon as possible.”[317] Lohse and the other key Siemens employees, whom the Americans were after, now realized that further debates were pointless.

---

[317] Hervorhebung von mir.

[317] Emphasis mine.

Am Morgen des Sonntag, dem 24. Juni, erfolgte der Abtransport der meisten der “befohlenen Herren” und ihrer Familien. Einigen mag es zur Beruhigung gedient haben, daß der unmittelbar vor der Evakuierung in Arnstadt auftauchende Werner von Siemens aus der Sicht der Konzernleitung keine prinzipiellen Bedenken gegen das amerikanische Vorhaben erhob. Dies genügte freilich nicht allen, um sich auf das Abenteuer der ungewissen Reise einzulassen. Ein leitender Angestellter, Wilhelm Vox, weigerte sich am Sontag noch immer mitzufahren. Daraufhin wurde er von der Besatzungsmacht verhaftet und gesondert abtransportiert. Wenige Tage später fand auch er sich in der US-Zone wieder.

Neben den leitenden Angestellten und deren Familien fuhren die Amerikaner aus dem Arnstadter Werk überdies 18 mit Maschinen und elektrotechnischen Geräten beladene Lastwagen über die Zonengrenze. Direktor Lohse und seinem engsten Mitarbeiter, die darauf bestanden, die Abwicklung auch in anderen Werken noch selbst zu überwachen, hatte die Besatzungsmacht das Recht eingeräumt, dem Haupttransport erst drei Tage später zu folgen. Als sie sich dann selbst nach Westen absetzten, sagten sie dem aufsichtsführenden amerikanischen Offizier unverhohlen ins Gesicht, daß sie “das feste Bewußtsein hätten, nicht eine Fabrik aufzubauen, wohl aber in ein Gefangenenlager zu kommen”.

On the morning of Sunday, 24 June, most of the “commanded gentlemen” and their families were transported away. Some may have been reassured by the fact that Werner von Siemens, who appeared in Arnstadt immediately before the evacuation, did not raise any objections in principle to the American plan from the point of view of the company management. This, of course, was not enough for everyone to embark on the adventure of the uncertain journey. One senior employee, Wilhelm Vox, still refused to go along on Sunday. As a result, he was arrested by the occupying forces and taken away separately. A few days later he too found himself in the U.S. zone.

In addition to the executives and their families, the Americans also drove 18 trucks loaded with machines and electrotechnical equipment from the Arnstadt plant across the zone border. Director Lohse and his closest colleague, who insisted on still supervising the processing in other plants themselves, had been granted the right by the occupying forces to follow the main transport only three days later. When they then set off westward themselves, they blatantly told the supervising American officer to his face that they “were firmly aware that they were not going to build a factory, but that they were going to a prison camp.”

Die Amerikaner haben nicht nur aus Arnstadt, sondern aus allen größeren Siemens-Werken Mitteldeutschlands Spitzenkräfte zwangsevakuiert, aus Rudolstadt ebenso wie aus Gera und aus Beendorf bei Helmstedt oder Molsdorf bei Erfurt.[318] Allein aus Gera und Arnstadt waren es einschließlich der Familienangehörigen ungefähr 125 Personen, darunter insgesamt gewiß mehrere Dutzend erstrangige Kräfte des Konzerns, denn Ende 1945 fanden sich noch immer über 30 von ihnen im Gewahrsam von FIAT; zwei Drittel kamen aus Arnstadt, wo sich die meisten Siemens-Angehörigen gesammelt hatten.[319]

The Americans forcibly evacuated top personnel not only from Arnstadt, but from all the larger Siemens plants in central Germany, from Rudolstadt as well as from Gera and from Beendorf near Helmstedt or Molsdorf near Erfurt.[318] From Gera and Arnstadt alone, there were about 125 people, including family members, among them certainly several dozen first-rate employees of the company, because at the end of 1945, more than 30 of them were still in FIAT custody; two thirds came from Arnstadt, where most Siemens employees had gathered.[319]

---

[318] Die Evakuierungen an diesen Standorten sind verschiedentlich erwähnt, so in Lohses Schilderung selbst, aber auch bei Gimbel, U.S. Policy and German Scientists, S. 440, sowie in dem Bericht Marschall Schukows an Stalin von Ende Juni 1945 ("Marshall Zhukov's Report on Removal by the Allies of Equipment and other Property from the factories in the Soviet Zone of Occupation"), auf den weiter unten näher eingegangen wird; abgedruckt in: FRUS, Conference of Berlin, II, S. 906 ff.

[319] Vgl. neben dem Bericht von Direktor Lohse die von FIAT zusammengestellte Liste aus Mitteldeutschland evakuierter Wissenschaftler und Techniker v. 19. 12. 1945; NA, RG 243, European War, G-2 Library, Entry 36, Envelope 760. In dieser umfangreichen Aufstellung, die etwa die Hälfte der insgesamt zwangsevakuierten Experten aufführt, findet sich auch der Name von Dr. Wilhelm Vox, der sich zunächst geweigert hatte, Arnstadt mit den Amerikanern zu verlassen, und daraufhin von der Besatzungsmacht verhaftet worden war.

[318] Evacuations at these sites are mentioned variously, as in Lohse's account itself, but also in Gimbel, U.S. Policy and German Scientists, p. 440, and in Marshal Zhukov's report to Stalin of late June 1945 ("Marshal Zhukov's Report on Removal by the Allies of Equipment and other Property from the factories in the Soviet Zone of Occupation"), discussed in more detail below; reprinted in: FRUS, Conference of Berlin, II, pp. 906 ff.

[319] See, in addition to the report by Director Lohse, the list of scientists and technicians evacuated from central Germany compiled by FIAT, dated December 19, 1945; NARA, RG 243, European War, G-2 Library, Entry 36, Box 760. This extensive list, which lists about half of the total number of forcibly evacuated experts, also includes the name of Dr. Wilhelm Vox, who had initially refused to leave Arnstadt with the Americans and was subsequently arrested by the occupying forces.

Die Zwangsevakuierten von Siemens wurden in das württembergische Heidenheim an der Brenz gebracht. Hier kamen sie zunächst in ein stark bewachtes, mit einem Drahtverhau umgebenes Barackenlager. Bald konnten sie in ein Schulhaus umziehen, und nach und nach wurden sie gewahr, daß sie ihr Schicksal mit Hunderten anderer "Internierter"—so Direktor Lohse—aus Thüringen teilten: "Die wahre Ursache des Transports nach Heidenheim konnte sehr schnell übersehen werden", berichtete er im November 1945 seiner Firma. "Offensichtlich hatte die amerikanische Regierung Wert darauf gelegt, alle Kräfte, die evtl. für den Wiederaufbau bzw. die Fertigungsfortsetzung von V-Waffen nützlich sein könnten, außerhalb Thüringens zu konzentrieren ... Die örtlichen militärischen Stellen der Amerikaner waren jedoch über die Absichten nicht im geringsten im Bilde. Sie hatten, wie mir ein amerikanischer Offizier selbst mitteilte, lediglich den Befehl vom Hauptquartier, as Thüringen verbrachte deutsche Fachkräfte unbedingt und sicher festzuhalten." Von einer "Unzahl von englischen und amerikanischen Militärkommissionen sämtlicher Truppenteile" wurden die Internierten ausgefragt, berichtete Lohse, aber keiner der Offiziere "konnte jemals auf unsere Frage antworten, ob und wann wir aus unserer Internierung entlassen würden". Auch die Bemühungen um Freilassung, die sofort von der Siemens-Gruppenleitung in München eingeleitet wurden, blieben zunächst ohne Erfolg. Erst Anfang Dezember konnten ungefähr zwei Drittel der in Heidenheim festgehaltenen Firmenmitglieder an den Erlanger Konzernstandort übersiedeln. Sie hatten sich weiterhin als interniert zu betrachten, konnten sich aber nun frei in der US-Zone bewegen. Verlassen durften sie das amerikanische Besatzungsgebiet nicht, wofür Direktor Lohse der Militärregierung persönlich zu bürgen hatte.

The forced evacuees from Siemens were taken to Heidenheim an der Brenz in Württemberg. Here they were initially placed in a heavily guarded barracks camp surrounded by a wire enclosure. Soon they were able to move into a schoolhouse, and gradually they became aware that they shared their fate with hundreds of other "internees"—as Director Lohse said—from Thuringia: "The true cause of the transport to Heidenheim could very quickly be overlooked," he reported to his company in November 1945. "Obviously, the American government had attached importance to concentrating outside Thuringia all forces that might be useful for the reconstruction or continuation of the production of V-weapons.... The local American military authorities, however, were not in the least aware of the intentions. They had, as an American officer himself told me, only the order from headquarters to hold German specialists deported to Thuringia absolutely and securely." Internees were questioned by a "number of English and American military commissions of all troop units," Lohse reported, but none of the officers "was ever able to answer our question as to whether and when we would be released from our internment." Efforts to secure release, which were immediately initiated by Siemens Group management in Munich, were also initially unsuccessful. It was not until early December that about two-thirds of the company members held in Heidenheim were able to move to the Erlangen group location. They still had to consider themselves interned, but could now move freely within the U.S. zone. They were not allowed to leave the American occupation zone, for which Director Lohse had to personally vouch to the military government.

Die Labors und Betriebsstätten der Telefunken, Gesellschaft für drahtlose Telegraphie m.b.H., die ebenfalls Bauteile für die V-Waffenproduktion entwickelt und hergestellt hatte, fanden bei den Amerikanern ähnliche Aufmerksamkeit wie die Fabriken des Konkurrenzunternehmens Siemens. Bereits am 16. Juni transportierte die Army (deren Ordnance Teams ja schon seit Ende Mai die Genehmigung hatten, Experten, die in irgendeiner Weise mit dem deutschen Raketetenprogramm verbunden waren, nach Westdeutschland zu bringen) aus der Fertigungsstätte in Bad Liebenstein im thüringischen Landkreis Meiningen den Konstrukteur Professor Fritz Schröter mit Frau und Tochter ab, nach dem sicheren Eindruck des Unternehmens eine Aktion "rein militärischen Charakters"[320]. Neben der Wegführung des prominenten Betriebsstättenleiters gab es auch freiwillige Abwanderungen mehrerer wichtiger Mitarbeiter und ihrer Familien, da die Firmenleitung—vermutlich unter dem Eindruck der bevorstehenden sowjetischen Besetzung—beschlossen hatte, ire während des Krieges nach Mitteldeutschland ausgelagerten Betriebe zurückzuführen. Als ester Sammelpunkt war Göttingen bestimmt worden, wohin deshalb im Laufe des Juni neben den Betriebsangchörigen auch Apparate, Geräte und Konstruktionsunterlagen gebracht wurden. In einer Aufstellung der Wirtschaftskammer Meiningen war sorgsam unterschieden zwischen denjenigen, die "abtransportiert" worden waren, und denen, die den Ort "freiwillig verlassen" hatten oder "unbekannt verzogen" waren. Einige der Abtransportierten—so Professor Hans Rukop (Röhrenexperte), Professor Paul Günther (Radarfachmann), Graf Michael von der Schulenburg oder Erich Chytrek, der auf dem Felde der Quarzkristalle forschte—befanden sich noch Ende des Jahres im Gewahrsam der alliierten Field Intelligence Agency, Technical. Aus dem Telefunken-Labor in Bad Blankenburg bei Rudolstadt hatte die Army bei ihrem Abzug neben wertvollen Apparaturen zwanzig Experten auf dem Gebiet der Funktechnik fortgeschafft.[321] Der Bestimmungsort der meisten Telefunken-Koryphäen war wie der ihrer Siemens-Kollegen das württembergische Städtchen Heidenheim.

The laboratories and operating facilities of Telefunken, Gesellschaft für drahtlose Telegraphie m.b.H., which had also developed and manufactured components for V-weapon production, attracted similar attention from the Americans as the factories of the rival company Siemens. As early as 16 June, the Army (whose Ordnance Teams had already been authorized since the end of May to bring experts in any way connected with the German missile program to West Germany) transported the designer Professor Fritz Schröter with his wife and daughter from the manufacturing plant in Bad Liebenstein in the Thuringian district of Meiningen, according to the company's clear impression an action of "purely military character."[320] In addition to the departure of the prominent plant manager, there were also voluntary departures of several important employees and their families, since the company management—presumably under the impression of the impending Soviet occupation—had decided to return their operations that had been outsourced to central Germany during the war. Göttingen had been designated as the main assembly point, to which not only the employees but also apparatus, equipment, and design documents were brought in the course of June. In a list compiled by the Meiningen Chamber of Commerce, a careful distinction was made between those who had been "deported" and those who had "voluntarily left" the town or had "moved to an unknown address." Some of the deportees—such as Professor Hans Rukop (tube expert), Professor Paul Günther (radar expert), Count Michael von der Schulenburg, or Erich Chytrek, who was doing research in the field of quartz crystals—were still in the custody of the Allied Field Intelligence Agency, Technical at the end of the year. When the Army withdrew from the Telefunken laboratory in Bad Blankenburg near Rudolstadt, it had taken away twenty experts in the field of radio technology as well as valuable equipment.[321] The destination of most of the Telefunken luminaries, like that of their Siemens colleagues, was the small town of Heidenheim in Württemberg.

[320] Schreiben der Telefunkenbetriebsstätte Bad Liebenstein an den örtlichen Bürgermeister v. 30. 7. 1945. Dokument Nr. 37 im Anhang zu Fuchs, Besatzungspolitik der USA; vgl. auch ebenda, S. 139. NARA RG 40, Entry UD-75, Box 24, Folder Evacuation of German Equipment

September 22, 1945

Lt. J. K. TIBBY, U.S.N.R.
Executive Secretary TIIC
Room 2213, Munitions Building
Washington, D. C.

Dear Lt. Tibby,

Your letter of September 12 requested comments on five questions concerning evacuation of manufacturing equipment to the United States from Germany

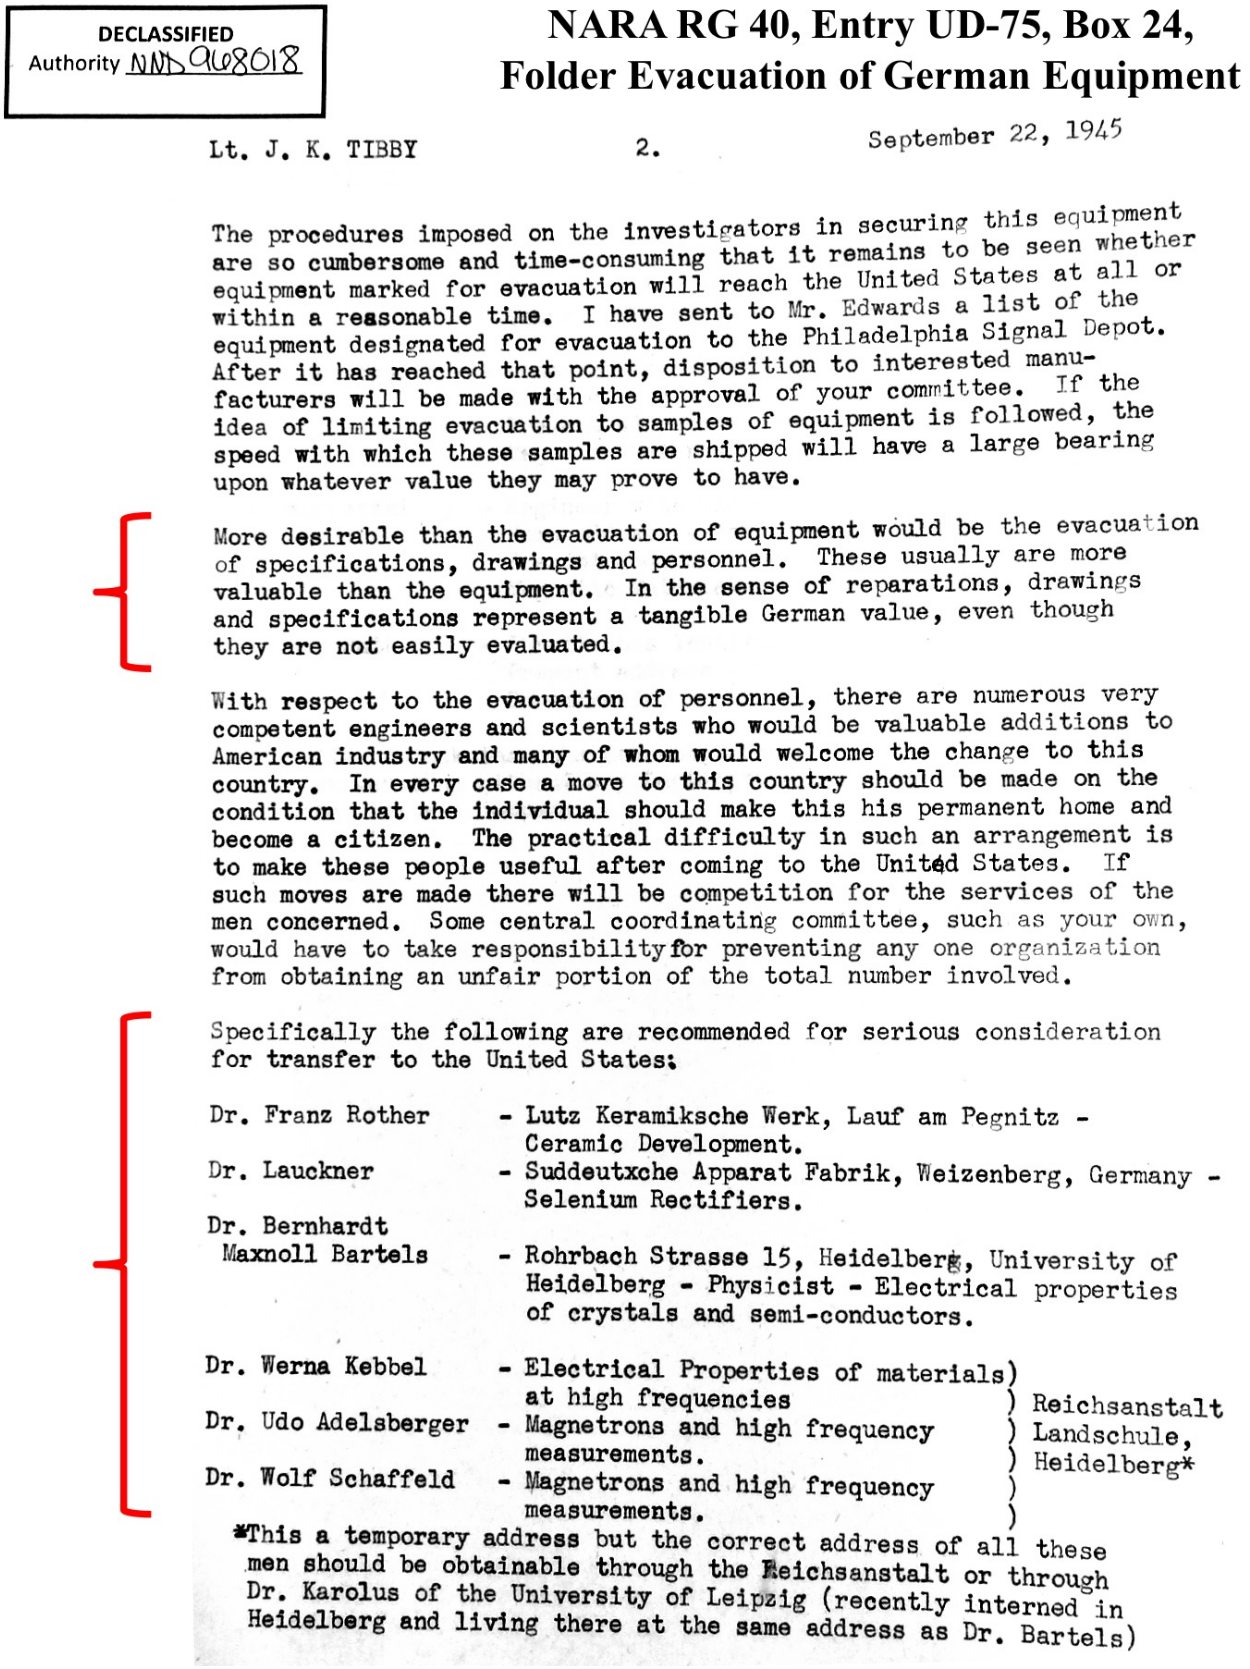
The first reaction to the general question is that there is much excellent manufacturing equipment in Germany which could be used for production in the United States. However, this reaction must be tempered by careful consideration of what effect the evacuation of equipment from Germany to the United States will have upon economics of American industry.

For example, there is a large amount of precision machinery such as, jig borers, jig mills and jig grinding machinery of excellent design and relatively new, that would find a ready market in the United States if cheaply priced. It is not all clear that such a move would relieve any potential unemployment condition that may exist in this country and it is reasonably to be anticipated that such a move would be resisted by our own manufacturers of high precision machinery.

Evacuation of machinery on a large scale requires study as to whether the cost of removal, transportation and reinstallation with whatever modifications that may be required in service fittings, power supplies, etc., to meet American practices would be less than the cost of reproduction in this country.

In my opinion, no mass evacuation of German industrial equipment to the United States should be undertaken. Any evacuation should be consistent with pre-war exports to the United States of productive facilities normally purchased from Germany and unavailable from our own manufacturers, and should be limited to samples of those novel items of equipment representing improvement over American equipment. Numerous samples of this kind have already been marked for shipment to the United States by TIIC investigators. When received the interested industries should be advised so that their performance and characteristics can be observed.

Figure B.258: In summer 1945, the U.S. military and AT&T "evacuated" German scientists who developed traveling wave tubes for the "master standard transmitter" radio-inertial guidance system on rockets, including Erhard Horn, Adolf Lohse, Herbert Schnitger, and Dieter Weber (plus many other electronics experts), as well as their equipment and information [NARA RG 40, Entry UD-75, Box 24, Folder Evacuation of German Equipment]. See also p. 1221 and Section E.2.



DECLASSIFIED
Authority NND968018

NARA RG 40, Entry UD-75, Box 24, Folder Evacuation of German Equipment

Lt. J. K. TIBBY 2. September 22, 1945

The procedures imposed on the investigators in securing this equipment are so cumbersome and time-consuming that it remains to be seen whether equipment marked for evacuation will reach the United States at all or within a reasonable time. I have sent to Mr. Edwards a list of the equipment designated for evacuation to the Philadelphia Signal Depot. After it has reached that point, disposition to interested manufacturers will be made with the approval of your committee. If the idea of limiting evacuation to samples of equipment is followed, the speed with which these samples are shipped will have a large bearing upon whatever value they may prove to have.

More desirable than the evacuation of equipment would be the evacuation of specifications, drawings and personnel. These usually are more valuable than the equipment. In the sense of reparations, drawings and specifications represent a tangible German value, even though they are not easily evaluated.

With respect to the evacuation of personnel, there are numerous very competent engineers and scientists who would be valuable additions to American industry and many of whom would welcome the change to this country. In every case a move to this country should be made on the condition that the individual should make this his permanent home and become a citizen. The practical difficulty in such an arrangement is to make these people useful after coming to the United States. If such moves are made there will be competition for the services of the men concerned. Some central coordinating committee, such as your own, would have to take responsibility for preventing any one organization from obtaining an unfair portion of the total number involved.

Specifically the following are recommended for serious consideration for transfer to the United States:

Dr. Franz Rother - Lutz Keramiksche Werk, Lauf am Pegnitz - Ceramic Development.

Dr. Lauckner - Suddeutxche Apparat Fabrik, Weizenberg, Germany - Selenium Rectifiers.

Dr. Bernhardt Maxnoll Bartels - Rohrbach Strasse 15, Heidelberg, University of Heidelberg - Physicist - Electrical properties of crystals and semi-conductors.

Dr. Werna Kebbel - Electrical Properties of materials at high frequencies)
Dr. Udo Adelsberger - Magnetrons and high frequency measurements.) Reichsanstalt Landschule, Heidelberg*
Dr. Wolf Schaffeld - Magnetrons and high frequency measurements.)

*This a temporary address but the correct address of all these men should be obtainable through the Reichsanstalt or through Dr. Karolus of the University of Leipzig (recently interned in Heidelberg and living there at the same address as Dr. Bartels)

NEW TUBE EXPANDS RADIO POSSIBILITIES

Device Can Send 10,000 Phone Calls at Once, 100 Million Wired Words a Minute

WIDENS TELEVISION FIELD

Old Broadcast Band Enlarged 800 Times and Improves Service in Accordance

By T. R. KENNEDY Jr.

A novel vacuum tube, not much larger than an ordinary radio receiving bulb, was made public here yesterday. It is expected to do as much for the future of very-high-frequency nation-wide communication as the deForest "audion" did for the broadcast and world-wide telephony and telegraphy pioneers a quarter of a century or more ago.

A product of the Bell Telephone Laboratories, the new device is said to make possible a "wave-guide" network of coast-to-coast proportions over which 10,000 telephone conversations may go simultaneously, or all the television programs needed for all the video stations likely to be operating in this country in years to come.

A wave-guide is a hollow metal tube through which "radio" waves may move like water. Wave-guides came into their own during the war, when no high-power radar could get along without them. The principle now is being applied to communication purposes.

Far Reaching in Significance

So far-reaching and significant are the new horizons thus created that experts hesitate to predict the full possibilities of such a network, which now seem to be appreciably nearer by the development of the new tube, technically known as a "traveling-wave" tube.

For instance, a wave-guide system set up to transmit and receive dots and dashes of the Morse code instead of telephone speech or television images would carry easily the equivalent of one hundred million words in dots and dashes each minute, it was said. An ordinary radio channel on the average world-wide frequencies carries only a few hundreds of words a minute.

The new tube has been expanded in other ways besides that of channel width. In the laboratory it has been able to "amplify" a signal millions of cycles wide so effectively as to produce what engineers call "a power gain of 10,000 times." When doing this, the tube operates over a band 800 megacycles wide (800 times as wide as the whole broadcast band from WQXR to above WMCA on the dial), and does it "1,000 times better" than the best other tubes of conventional design.

Figure B.261: One year later, in summer 1946, AT&T publicly claimed that it had just invented the traveling wave tube, which would revolutionize communications [NYT 1946-07-06].

Untersuchungen über selbsterregte Schwingungen in der Wanderfeldröhre

Von Herbert Schnitger und Dieter Weber

(Mitteilung aus dem Fernmeldetechnischen Zentralamt)

Inhalt

An üblichen Wanderfeldröhren (traveling-wave tubes) werden ohne äußere Schaltmittel sehr gut definierte, kräftige Schwingungen zwischen 5 und 50 cm beobachtet. Es lassen sich Schwingbereiche festlegen, deren mittlere Wellenlänge mit der Spannung wächst. Der Wellenlängenanstieg kann an einer Röhre bis zu 1:3 betragen bei fast gleich großer Spannungserhöhung. Innerhalb eines Schwingbereichs fällt die Wellenlänge schwach mit der Spannung; bei z. B. 24,6 cm beträgt die Frequenzänderung etwa 50 kHz pro Volt. Die erhaltenen Ergebnisse werden unter Benutzung der Theorie von I. R. Pierce diskutiert. Versuche mit Röhren, bei denen sich die Wendel außerhalb des Glaskolbens befindet, weisen auf die Möglichkeit einer noch einfacheren Variation der Wendeleigenschaften hin.

Im Jahre 1946 berichtete Kompfner [1] erstmalig über die Wanderfeldröhre (traveling-wave tube), die eine neuartige Laufzeitröhre für das Dezimeter- und Zentimetergebiet darstellt. 1947 veröffentlichte dann Pierce [2] eine umfassende Theorie, die die wichtigsten Eigenschaften dieser Röhre mit meist guter Annäherung wiedergibt. Der hier vorliegende grundsätzlich neue Mechanismus einer Wechselwirkung zwischen Welle und Elektronenstrahl und die überraschend guten Ergebnisse, die Kompfner bereits mit den ersten Verstärkerröhren dieser Art erzielte, regten schnell zu verhältnismäßig zahlreichen weiteren Untersuchungen an [3 bis 12]. Der experimentelle Anteil dieser Arbeiten ist aber noch nicht sehr umfangreich. Eigene Untersuchungen zeigten uns, daß z. B. der Bau von Verstärkern sehr durch eine leicht einsetzende Selbsterregung erschwert wird. Diese Selbsterregung wurde von Kompfner bereits erwähnt, aber nicht näher beschrieben. Um die Selbsterregung systematisch unterdrücken zu können, schien es uns daher zweckmäßig, sie experimentell zu untersuchen. Die erhaltenen Ergebnisse, über die im Folgenden berichtet wird, sind auch für die Theorie der Wanderfeldröhre, insbesondere für die Berechnung der Eigenschaften der Wendeln, interessant. Einige Besonderheiten des Schwingungsmechanismus könnten ferner dazu führen, daß die Wanderfeldröhre trotz ihres vorerst noch geringen Wirkungsgrades und des zur Zeit noch großen Aufwandes eine gewisse Bedeutung als Oszillatorröhre erhält, so z. B. für Meßsender mit besonderen Anforderungen, wie sie etwa die Einstellung der Frequenz über mehrere Oktaven durch ausschließliche Änderung einer Gleichspannung darstellt.

Aufbau und Funktion der Wanderfeldröhre

Den Aufbau der für die Messungen benutzten Wanderfeldröhren zeigt Bild 1. Die Röhre besteht aus zwei Hauptteilen: Der Elektronenspritze und der Wendel. Die Elektronenspritze erzeugt einen fadenförmigen Elektronenstrahl homogener Geschwindigkeit v_e, der die Wendel in Richtung der Achse durchläuft. Läßt man eine Welle auf der Wendel entlanglaufen, dann bewirkt die schraubenartige Struktur

Bild 1
a) Aufbau einer Wanderfeldröhre
b) Teil der Wendel mit Maßzahlen in mm

Figure B.262: It appears that Herbert Schnitger and Dieter Weber were not allowed to publish their own traveling wave tube work until much later, and much more quietly [Schnitger and Weber 1949].

SPECIAL MEMORANDUM NO 10

H-107

1. SUBJECT: V-2.
SOURCE : Reliable industrialists.

One of the institutes working on V-2 construction for the "Special Technical Commission of the USSR" in BLEICHENRODE (Harz) is the INSTITUT RABE, also located in BLEICHENRODE. Their speciality is the radio and television equipment of the V-2. At present this institute is very anxious to obtain "Cathode ray switches" and "Electrode ray switches" (Kathodenstrahlschalter und Elektrodenstrahlschalter) from other German radio industries as they themselves have failed to build them. These switches are based on the system of the "Braun Tube" and are used in the V-2 to send back the necessary data about the projectile's altitude, speed, direction of flight, etc.

Another institute working on similar type of equipment is the former SIEMENS A. G. in ARNSTADT (Thuringia), headed by Dr MUELLER and Dr GOBRECHT. This firm specializes in television tubes, super ikonoscopes and inverters which are used for the transmission of the target picture as registered by the nose of the missile and transferred to the base.

CHANCELLOR

2. SUBJECT: Aircraft Industry.
SOURCE : Two independent sources who reported essentially the same within five days of each other.

The JUNKERS plant in DESSAU is in the process of being dismantled and shipped to KOENIGSBERG (East Prussia). Preparations for the move have started around 1 October; the move itself is planned to be completed with all personnel and machines around 15 November.

At present approximately 1,200 technicians and skilled workers are employed in research and construction of the former fighter plane 262 and a bomber powered by four jet units. Other features of the bomber are one rocket unit under each wing with a propulsion power of 500 kg each for additional power take off and parachute brakes, as used today in British gliders.

Research for both these planes is practically completed.

CHANCELLOR

3. SUBJECT: Miscellaneous Industrial Information.
SOURCE : Reliable observer.

~~EXCLUDED FROM GENERAL DECLASSIFICATION SCHEDULE~~

a. According to official figures obtained from Russian sources, there are at present 28,000 skilled workers employed in the fine parts and precision instruments industry and an additional 13,550 in medical instruments industry throughout the entire Soviet Zone of Occupation in Germany. These figures are as of 15 October 1946.

b. It is reported from the typewriter factory of WALTER A. G. in DRESDEN that a new system is used by the SMA in order to have German industrial concerns converted into Russian corporations. The case of the WALTER A. G. is by no means the first one. This procedure has been used already for the past six to seven weeks.

Special Memorandum No 10, cont'd.

On 10 October a meeting was called by the Free German Trade Unions for all the workers in the factory. Several speakers pointed out to the assembly how advantageous it would be for the workers, if the factory were transformed into a Soviet enterprise. Examples of other factories were quoted. It was shown that their rations and general conditions were so much better and after two hours of talking an open vote was cast whether or not the assembled workers were in favor of signing a resolution to that effect. The large majority showed their agreement by raising their arms, a resolution was drawn up to that effect and addressed to the SMA. On [illegible] October the SMA had given their approval so that as of that date the firm WALTER A. G. is to be considered a Soviet enterprise.

c. Marshall SOKOLOWSKI has given orders to his economic section, represented by civilian engineer SOLOWJEW to find out the following details about industrial development in the three western zones of Germany:

(1) Present state of repair of industries and factories.
(2) Possibilities of repair, what repairs would be necessary to obtain a maximum of results.
(3) Present capacity of industries in running order now as compared to peace time capacity.
(4) Property relations and legal conditions of main industries.
(5) What is source of raw material for factories working at present.
(6) Destination of finished products.

d. Reliable source informs us that in the opinion of all industrialists ever talked to, the production in the Soviet Zone will have to be stopped completely around February or March, as all existing stocks of raw materials will be exhausted by that time.

OFFICE OF MILITARY GOVERNMENT FOR GERMANY (US)

SPECIAL INTELLIGENCE)
:
MEMORANDUM NO.....24)

D- 138175

APO 742, US Army
22 November 1946

Subject: Production of V-Weapons in Soviet Zone.
Source : Extremely reliable traveller who went to considerable trouble to double check the information given below.

According to source, there are at present only four plants in the Soviet Occupation Zone of Germany manufacturing V-Weapons. The largest of all is the GOTHAER WAGGONFABRIK (Railroad car factory of Gotha) located in GOTHA, employing approximately 2,600 workers on a two shift basis of ten hours per shift. This plant has a research staff of approximately 400 men, the remaining 2,200 workers being employed in actual production. Some V-2's are still being manufactured. However, emphasis is placed on V-2's without a warhead; and on an improved V-2 model, called V-3.

CONFIDENTIAL
Classification cancelled (or changed) to
by authority of
Date 12 Aug. 1952

The second largest factory is in the Soviet Sector of Berlin, the AEG KOEPENICK in OBERSHOENEWEIDE (not the notorious "Kabelwerk", whose workers were evacuated to some extent on 22 October 1946). This plant employs approximately 1,600 workers, mainly on research on V-3, but at least half of the staff is engaged in actual production.

The third plant is located in BLEICHERODE, already well known for its activity. Approximately 1,200 workers and employees, including a research staff of undetermined size.

The smallest of all V-plants is located at NORDHAUSEN with approximately 800 workers, working on V-2 exclusively. As far as could be determined, no research takes place at this center.

Some of the accessories for the V-weapons are being manufactured outside the above mentioned four plants, notably radio equipment and remote control equipment, which is the weak spot in Soviet research. So far, for instance, none of the V-2's manufactured under Russian supervision carried a cathode ray switch, a piece of equipment indispensable for the relay to the base, of data about height, direction of flight, speed, etc. Hence, the occasional appearance of guided missiles of unknown origin in the Baltic. (For cathode ray switches, see Special Memorandum No. 10, Office of AC of S, G-2, Berlin District, dated 23 October 1946).

The sleighs and launching platforms for the V-2 are believed to be manufactured in the factory KERNER (or Gerner or Koerner) in KRIMMITSCHAU (Land Saxony), a plant under complete Soviet supervision, employing approximately 140 workers.

Subject: V-2 Production in SovZone
Source : Extremely Reliable.

BLEICHERODE in the Harz mountains is still doing fine in the production of V-2 rockets. It was reported from this office that dismantling was going on, but it was stopped as of 1 December. The general procedure for dismantling of installations very dear to the Soviet heart is the following as illustrated best by BLEICHERODE.

As soon as Soviet troops took over the V-2 plants, they did everything in their power to get it reorganized and re-equipped. As soon as this was done, they started production. When they saw that the finished product was satisfactory, they began to dismantle the plant for the first time. The dismantling was not carried through completely, but was halted as soon as about half was taken. Together with the machinery some personnel was taken out, to be shipped to the USSR in order to set up the machinery which was confiscated and complete it with more later.

In the meantime the plant in BLEICHERODE was being rebuilt under supervision of German and Soviet engineers. Once rebuilt, production was started all over again and as soon as satisfactory results were achieved, the dismantling was continued. In this way, Soviet authorities enrich their own country by building up some priceless industries and on the other hand they see to it that the original plant in Germany is reconstructed and re-equipped after each time. Thus, they would be able theoretically to continue an uninterrupted flow of industries from Germany to the Soviet Union.

This procedure is known to have been applied to all V-weapon plants in BLEICHENRODE, NORDHAUSEN, GOTHA and BERLIN. In BLEICHERODE the installations were dismantled for the fourth time; in NORDHAUSEN for the sixth time; in Berlin only once; conditions in GOTHA are unknown.

The institution responsible for the manufacture and research of V-weapons in BLEICHERODE is the so-called "Zentralwerk Rabe", which consists of seven departments:

1. Remote control, steering and navigation.
2. Fuel
3. Aerodynamic
4. Explosives
5. Materials
6. Testing
7. Manufacture

Z

EXCLUDED FROM GENERAL
DECLASSIFICATION SCHEDULE

CONFIDENTIAL

Departments one to six are housed above surface, while department seven, Manufacture, is installed in subterranean factories. The chief difficulties encountered at present are first of all with remote control, and secondly with material. Considerable trouble was had with the density of the welded fuel containers. Among the two containers there are 99 yards of welding seam; if only four or five drops of fuel pass through these seams, an explosion is likely to occur. It is believed, however, that this particular difficulty was overcome.

Memo No 48, cont'd.

All radio and remote control equipment is manufactured on subcontract by the former SIEMENS Plant in ARNSTADT (Thuringia) while all other parts are manufactured directly in BLEICHERODE. The radio equipment will enable the rocket to send back to base 24 different signals within three seconds, mainly about altitude, airspeed, groundspeed, steering reaction and television view of the objective.

A new tactical use of V-2 rockets is intended. It is planned to equip one of the rockets with such an extensive radio and remote control system that route deviations of any kind would be hil. This rocket would not carry any explosive whatsoever. On the other hand, this rocket would be equipped with such radio installations to be able to control and steer an undetermined number of other rockets, fired at the same time. Technically this would be possible; it would save space, as the remote control equipment in the dependent rockets could be reduced considerably in favor of explosives. At the same time the "mother rocket" would be dead ballast, with the sole purpose of guiding the dependent rockets, thus the remote control problem would be limited to one rocket only.

Personnel working in BLEICHERODE are partly German and partly Russian, both workers and engineers. At present there is some unrest among the German contingent, due to repeated and persistent rumors that the next evacuation of skilled labour will take place sometime in January.

Dear Mr. Webb:

Confirming our telephone conversation of yesterday, we would like to arrange to send Mr. J. E. Clark, our expert on vacuum tubes, to visit with you and view the German vacuum tubes employing the ceramic to metal seal. Mr. Clark will get in touch with you in the next few days by telephone to make a specific engagement.

Very truly yours,

J R Townsend

CONDITIONS OF PURCHASE

Bills will be paid in accordance with the following schedules unless otherwise agreed:

Schedule 1 "10 day bills":—Bills dated from 1st to 10th not later than 15th; from 11th to 20th not later than 25th; from 21st to end of month not later than 5th of following month.

Schedule 2 "15 day bills":—Bills dated from 1st to 15th not later than 23rd; from 16th to end of month not later than 8th of following month.

Schedule 3 "30 day bills":—Not later than 20th of month following date of bill.

No charges allowed for packing or cartage, unless otherwise agreed.

All specifications, drawings, technical information or data furnished to you hereunder shall be used only in the manufacture of material furnished to us and shall be returned to us upon request.

All patterns, dies, moulds and tools which are furnished by us shall be returned to us promptly upon completion of the work called for in this order.

By accepting this order you hereby warrant that the material to be furnished hereunder will be in full conformity with the specification, drawing or sample and agree that this warranty shall survive acceptance of and payment for the material, and you agree to save us harmless from any loss, damage or expense whatsoever, including attorney's fees, that we suffer as a result of your failure to abide by such warranty. We reserve the specific right to have rejected material replaced by you or not at our option and at the purchase price stipulated in this order. Material rejected shall be returnable to you for full credit at the price charged, plus transportation charges. We reserve the further right to accept a part of any shipment which fulfills our specifications and to reject any part which does not fulfill such specifications and to consider this order breached to the extent of the amount of the rejected material.

By accepting this order you certify that you comply with the "Fair Labor Standards Act, 1938, as amended." Should we receive credible evidence that you have not done so we may cancel this order and refuse to take delivery under the same and may return goods delivered hereunder and obtain reimbursement therefor.

By accepting this order you hereby guarantee and agree that all machines, devices and materials furnished hereunder (and the normal use thereof) are and shall be free and clear of infringement of any valid patent, copyright or trademark, and that you will, at your own expense, defend any and all actions or suits charging such infringement and will save us, our customers and those for whom we may act as purchasing agent, harmless in case of any such infringement.

We are not bound by any printed matter on suppliers' acknowledgment forms or invoices which impose upon us conditions at variance with the terms of our contract or with this order.

Additional conditions on reverse side are part of this purchase order.

Dr. O. E. Buckley
President
Bell Telephone Laboratories
463 West Street
New York 14, New York

My dear Mr. Buckley:

I am enclosing a copy of a recent press release which was carried throughout the United States and Canada describing an infra-red night-seeing device used by the Germans.

This dispatch has aroused such interest, and inquiries concerning it continue to arrive. I am enclosing also a copy of a typical inquiry and my reply.

I believe it would be worthwhile for your company to undertake production of such a device, and shall be glad to consult with your engineers and furnish all the information I have concerning it.

I have a "Bilwandler" (image changer) tube here which is available for examination. This is the photo-sensitive tube which converts the infra-red image to visible light.

In case you find it worthwhile to undertake such development, I should be glad to have you advise me.

Sincerely yours,

Edwin Y. Webb, Jr.
Chief, Communications Unit
Technical Industrial Intelligence Branch

Mr. Walter S. Gifford
President
The American Telephone and Telegraph Company
195 Broadway
New York 7, N. Y.

My dear Mr. Gifford:

I am very grateful to you for your prompt response to my letter of 18 March and I appreciate sincerely your sending me your portrait. It will be a prized addition to my office.

If, upon your next visit to Washington, you find it convenient, I should like very much to see you and if your time permits, have lunch or dinner with you.

The work here continues to become more active and more valuable. Recently, 25 tons of German miniature vacuum tube machinery of novel design arrived and I am negotiating now to have it installed and operated for exploitation by all American Manufacturers. Also, there has just arrived, the 12-ton machine for making very small paper condensers by a novel and unique process of the Bosch Company. There has been extreme interest in these machines and I am in contact with Dr. Buckley and others in the matter of exploiting them. I shall be in touch with Mr. Rees also, so that he may advise others who might be interested.

Numerous other important machines are in transit at this time.

I send my thanks and good wishes to you.

Sincerely yours,

Edwin Y. Webb, Jr.

28 March 1946

Dr. O. E. Buckley
President
Bell Telephone Laboratories
463 West Street
New York 14, New York

My dear Mr. Buckley:

As you know a thorough search of the German activities in the scientific and technological field was undertaken by the United States Government upon the termination of the war in Europe in order to make the results of the German developments and techniques available to the special branches of the Government and to the Industry.

In this work the Industry as a whole and your organization have participated and have contributed freely to the accumulation of information of great value to the United States and to Industry.

As a result, a great number of the original German documents have been accumulated, such as technical reports, memoranda, data books, instruction books for special equipments, production plans and drawings for equipments and for component parts. Also, numerous samples of various components and of equipments, as well as special production tools and machines have been assembled. Technical reports have been prepared by the individual members of the investigating teams in Europe on subjects covering nearly the whole field of the scientific, technological and military activities of the Germans. All these reports and documents are being processed by the Government agencies in the United States and released for general use through the Publication Board of the Department of Commerce.

Severe shortage of adequately trained personnel available to these Agencies and the budgetary limitations do not permit the processing of the available information in as speedy a manner as is desirable. For this reason, this office has taken note of a suggestion, which came from the Industry, to draw upon the personnel of the Industry itself to speed up the process of review, analysis, digest and release of the information available in the form of documents and reports, equipments, samples and production tools.

With the transfer of the Technical Industrial Intelligence Branch to the Commerce Department, the activities of this organization are centered on the processing and distribution of the information on the technical achievements of Germany of exclusive interest to American Industry. It is most gratifying to me, therefore, to realize that the Industry is ready to participate actively and directly in the processing of the material assembled with the assistance of Industry and at a considerable expenditure of money, energy and time.

Dr. O. E. Buckley - 2 - 28 March 1946

In line with the policy of the Commerce Department, help and assistance will be rendered to the industrial representatives in their work. Such facilities as office space, secretarial and typing help, reproducing facilities, as well as the necessary access to all reports and documents, and to equipments, will be made available to them. In addition, all facilities of the Department will be available to the Industry in setting up new investigations in Germany or special projects which might be carried out in Germany with the participation of the German engineers and scientists.

I should like to know, therefore, if your Company would be willing to establish one or two men in Washington for a period of two or three months, on a Without-Compensation basis, in order to index the many thousands of reports on hand so that they can be effectively exploited for the benefit of your Company and Industry as a whole. I am making this same request of other interested companies.

Sincerely yours,

Dr. O. E. Buckley
President
Bell Telephone Laboratories
463 West Street
New York 14, N. Y.

My dear Dr. Buckley:

This is to notify you of the arrival in this Country of two important German industrial machines, the machine for manufacturing miniature (P-2000) vacuum tubes and the machine for manufacturing compact capacitors by the Bosch process.

The vacuum tube machinery was located by Messrs. McCarthy, Townsend, and Mertz, and is described briefly in Report C-62, which has been sent to you. I am negotiating with General Sarnoff of RCA in a plan for installing and operating this machinery and making it available for exploitation by The Industry, and I will notify you when plans are completed.

The condenser machine was located by Mr. Henderson of the Western Electric Co., in the Bosch plant at Stuttgart. It is described in Report C-2 and is protected by U.S. Patent 2,244,090, now in control of the Alien Property Custodian. This machine is being installed for operation by the Signal Corps at Bradley Beach, N. J., and requests to inspect it should be addressed to Lieutenant Colonel Salvatore Petrillo, Army Engineering Laboratories at Bradley Beach.

Soon I hope to be able to furnish you and others a sample condenser made by this machine. I will do this within a week or ten days if possible, before the machine is placed in operation.

Sincerely yours,

Edwin Y. Webb, Jr.

Dear Sir:

In an intelligence report written by Mr. J. L. Snyder of the General Ceramics Co. after his tour of inspection of German industrial plants in 1945 reference is made to an article by Dr. Rudolf Brill of the Institut für Anorganische und Physikalische Chemie at Darmstadt, Germany, on the subject of selenium rectifier investigations. The complete title of this article is "Erster Zwischenbericht über die Ergebnisse der Strukturuntersuchung an Selengleichrichtern". A copy of Dr. Brill's article was obtained and brought to this country, and I have been told both by Mr. Snyder and by Mr. G. D. Edwards of our Bell Laboratories' liaison group that the article is probably now in the intelligence archives under your supervision.

Please help us to locate this item. Can it be sent to us on loan, or should we ask for a photocopy?

Very truly yours,

John N. Shive

463 West Street
New York 14, New York

My dear Dr. Buckley:

Recently I transmitted a copy of 15 Intelligence Reports, C-51 through C-65, available through this office, concerning German research and development in the Communications field. These completed the series C-1 through C-65.

Ten additional reports, C-66 through C-75, are now available and are being sent to you, separately, today. In addition, Supplements to reports already processed are being included. These are, C-12A (Bartels), C-20A (Wesch), C-27A (Bosch), C-28A (Die Casting) and C-37A (Hass).

Reports above C-75 are being processed and will be sent to you when completed.

Within a short time, I will have on display in the Commerce Building approximately 200 items of German electronic equipment and approximately 200 different types of German vacuum tubes of novel design. I will have duplicates of many of these tubes which will be available for examination and research by interested companies. You may find it worth while to view this exhibit.

Sincerely yours,

Edwin Y. Webb, Jr.

Mr. R. E. Russell
Engineer
American Telephone and Telegraph Company
238 Hurt Building
Atlanta 3, Georgia

My dear Russell:

I was pleased to receive your recent letter and appreciate all the information you gave. If I am able to get down to Atlanta soon, you will be able to bring me up to date on all the news.

At this time, in Germany, investigators and associates of this Office have gathered more than 1-1/2 billion pages of technical information covering every phase of research and development. This information is composed of technical works, notebooks, and manuscripts which have not been published in Germany.

It is now our problem to screen this information to select the portion worth microfilming for dispatch to this Country. This task requires, of course, reading a vast amount of technical German, a representative portion being in the field of electronics and communications.

In connection with this work, I have a requirement for at least a dozen communications men who can read technical German to go to Germany for a period of six months. I am now working on this problem.

It occurs to me that due to your knowledge of the German language, and being a Communications Engineer, you are well qualified for this work. I should like to know, therefore, if you would accept an invitation to cooperate in this project in Germany. If so, I will undertake making formal arrangements for a furlough from your Company.

I offer you a P-5 Rating ($5180 per annum) plus $7 per diem for expenses. The Government will make all travel arrangements, of course, providing dispatch by either plane or boat. Since the work is carried out in cooperation with the Theatre Commander of the Military Forces, you will

- 2 -

be required to wear an Army uniform, and will abide by certain Army regulations.

Processing for dispatch will require four to six weeks. This includes obtaining passport, visa, etc., and if you accept the invitation, various questionnaires for passport, etc. will be sent to you in due course.

Please let me know if you are interested in this offer. I should like to know, also, of others in your acquaintance who might be interested.

Sincerely yours,

Edwin Y. Webb, Jr.
Chief, Communications Unit

Mr. J. B. Rees
Assistant Vice-President
The American Telephone
and Telegraph Company
195 Broadway
New York 7, New York

My dear Mr. Rees:

It was a pleasure to see you upon my recent visit to New York and hope I can see you again soon. From your office, Dr. Odarenko and I went to see Mr. Edwards of The Laboratories and had a successful visit with him. Dr. Odarenko, as you know, is preparing to go to Germany for a period of six months to act as my Hoechst Representative and direct activities there.

I have recently distributed 10 additional reports, C-66 through C-75, as well as an Index of the complete series (1 through 75). For your information, I am enclosing a copy of the Index and shall be glad to send you any reports you select. The complete set has been furnished to Dr. Buckley and Mr. Osborne. Incidentally, I enjoyed the paper delivered here yesterday by Dr. Buckley at the meeting of The National Academy of Science.

The German electronics equipment, composed of 200 items, as well as more than 1000 vacuum tubes, has arrived and I am now facing the problem of finding sufficient time to arrange it for display. Some very ingenious processes and novel ideas are disclosed in this equipment which will be of great benefit to the entire electronics and communications industries. The work here is so heavy that I am badly in need of help in order to handle it expeditiously and efficiently.

Upon your next visit to Washington I should appreciate your contacting me.

Sincerely yours,

Edwin Y. Webb, Jr.
Chief, Communications Unit

Mr. H. S. Osborne
Chief Engineer
The American Telephone
and Telegraph Company
195 Broadway
New York 7

My dear Mr. Osborne:

Towards the end of hostilities in Europe and under the sponsorship of the Government agencies of the United States, a plan was laid out for an exploitation of the German industrial, technological and scientific knowledge and practices. This plan has been in operation in Germany since the Spring of 1945.

On the basis of information so far assembled and processed, the results of the exploitation have proven of great benefit and of inestimable value to American Industry. The number of cases of direct applications of German technique and know-how to the industrial problems of this country have been increasing very rapidly.

As certain applications have been put into operation, new problems have arisen both in respect to details and certain fundamentals which call for additional information from Germany. Also, new ideas are being uncovered by industrial organizations and by the Government agencies from the evaluation of the already available German documents and equipment. These problems and ideas call for further exploratory activities in Germany and for the continuation of the work undertaken in Germany last year.

The over-all responsibility for these activities has recently been taken over by the Commerce Department. This responsibility covers the whole domain of the industrial, technological, and scientific activities. An important part of it is the telecommunications and electronics fields.

In order to carry on a systematic investigation in telecommunications and electronics, the Commerce Department, through the Communications Unit of the Technical Industrial Intelligence Branch, has succeeded in obtaining the services of Dr. T. M. Odarenko for a six months'

Figure B.281: Example of archival documents demonstrating the postwar transfer of microelectronics documents, hardware, personnel, and knowledge [NARA RG 40, Entry UD-75, Box 24, Folder Bell System]. NARA RG 40, Entry UD-75, Box 24, Folder Bell System

Mr. A. S. Osborne - 2 - 25 April 1946

duty in Europe as a representative of the Communications Unit. Dr. Odarenko spent several months in Europe during 1945 as a field investigator under TIIC and JIOA agencies. He is scheduled to depart for Europe early in May, and will be responsible there for the direction and organization of the exploitation activities relating specifically to telecommunications and electronics.

Until his departure to Germany, Dr. Odarenko will be available for discussion with your organization and its members of any problems relating to the technical intelligence work in Germany. His ability to be of general service to the Industry, and to your organization, will be the better if the problems you present to him are more concrete and definite. It is suggested, therefore, that should you have any problems calling for additional exploratory activities in Germany, you make use of his presence in this country, and discuss them with him immediately. The necessary arrangements for such discussions could be made through this office.

Sincerely yours,

Edwin Y. Webb, Jr.

O. E. BUCKLEY
PRESIDENT

June 17, 1946

MR. EDWIN Y. WEBB, JR.
Chief, Communications Unit
Technical Industrial Intelligence Branch
Office of Declassification and Technical Services
Department of Commerce
Washington 25, D. C.

Dear Mr. Webb:

We have been giving consideration to your suggestion that the Bell System loan one of its people to the Department of Commerce, to assist in abstracting and indexing selected portions of the technical material relating to communications which has been collected in that department and which is to be made available to industry. The Laboratories is agreeable to furnish this assistance, and we should have written earlier but for the delay which was caused while we canvassed our staff to select some one who would be suitable and also available for the period of time indicated in your letter.

Mr. J. Blanchard, a Member of our Technical Staff, will have some time AFTER ~~in~~ the next two to three months when he can be of assistance in this work. He is well qualified for this assignment since he has a considerable background in electronics, having been associated for a number of years with our tube development group. He will be in Washington June 17th and 18th on other Laboratories business, and will call you for an appointment on Wednesday the 19th, when the details of his assignment can be arranged.

I understand that the Department of Commerce will furnish Mr. Blanchard with office space, secretarial help etc., which he may require. The Laboratories will continue to pay his salary as well as his living expenses while in Washington.

I trust that this arrangement will meet with your approval and that Mr. Blanchard, in cooperation with representatives from other industries, will facilitate your plans for making this technical material more generally accessible.

Very truly yours,
O E Buckley
President

2 July 1946

Technical Industrial
Intelligence Branch

Mr. E. Bruce
Bell Telephone Laboratories, Inc.
463 West Street
New York 14, New York

My dear Mr. Bruce:

This is in reply to a letter of June 27 to the Department of Commerce concerning your interest in lead sulphide photo-electric cells developed in Germany. Unfortunately at this time, there are not as many as twelve of the 1-inch cell which you describe, as only those which have been captured in enemy equipment have been brought to this Country so far. Since receiving your letter, however, I have requested Dr. T. M. Odarenko, formerly of the Laboratories, who is at present my Director of Field Activities in Germany, to obtain more of these cells for research purposes.

The particular cell which you describe was manufactured by Carl Zeiss at Jena and is quite remarkable in its properties. You probably know that the cell is contained in a cylindrical plastic case approximately 1-inch in diameter and 3/16-inch thick. Light enters through a passage less than 1/16-inch in diameter. This particular cell was part of the receiving unit of the light-beam transmitters used by the German army. There were three such transmitters, the Licht Sprecher 60, Licht Sprecher 80 and the large Licht Sprecher 250. The Licht Sprecher 80 operates up to distances of five miles, the light source being a 2-volt bulb. You may see the Licht Sprecher 80 system in operation in this Office at any time.

Although the twelve cells which you desire are not available, I am glad to send you separately, one cell which has been removed from a light-beam transmitter. You may study this cell, disassembling it as necessary, in order to obtain as much information from it. This cell is being presented to you on the basis that you will furnish this office a copy of your report on the results of your research.

There are numerous reports available through the Publication Board of the Department of Commerce concerning German development of fluorescent screens and photo-sensitive cells which I believe will be worth while in your work. I am in correspondence with Dr. Buckley, Dr. Bown, Mr. Quarles, Mr. Edwards, Mr. J. E. Clark and others of the Laboratories, who are familiar with the work of this Office, and it may be that you can obtain additional information in which you are interested from them.

I hope that you will obtain worth while information from this cell and would like to hear from you concerning your results.

Sincerely yours,

Edwin Y. Webb, Jr.

Room 3E-200
Pentagon Building
Washington, D. C.

Dear General Ingles:

In cooperation with the Signal Corps and for the benefit of the Industry, the Office of Technical Services of the Department of Commerce is arranging a display of Captured Enemy Communications Equipment. Approximately three tons of this equipment have already been obtained from storage at the Holabird Signal Depot at Baltimore and will be delivered to Industry for research purposes.

There remains at the Depot captured equipment approximating 20 tons which is to be disposed of by the Signal Corps. In order to exploit completely all of the novel features of this equipment, resulting in greatest benefit to the Industry, it appears appropriate that custody of the remaining equipment be given to this Department.

In view of this, we ask that you make this transfer and advise this office of the details incidental to it. At the present time, the Department has no storage space available in Washington. Pending acquisition of suitable space, we would appreciate your agreeing to permit the equipment to remain at Holabird so that accredited manufacturers can examine and requisition it through proper Department channels.

Very truly yours,

ROBERT FRYE
Assistant Director

RF/vk
E.Webb/RF/vk

Dear Mr. Webb:

Since returning from my vacation I have learned that you succeeded in obtaining an extension of your leave and are still on the job in Washington.

It has been decided that I am to go down next week and begin work on the abstracting and indexing scheme you have suggested that we participate in. I shall probably be seeing you on Monday morning.

Yours sincerely,

J Blanchard

Washington, D. C.

Dear Mr. Webb:

Thank you very much for the exceedingly pleasant visit which Mr. J. E. Clark and I had with you on August 28. We found your display of captured German and Japanese communications equipment not only highly instructive but exceptionally well organized.

You may rest assured that the tubes which you kindly gave us will receive a most thorough examination. Any observations which we believe of importance will be communicated to you.

During our visit you will recall that we came across some German glass-cementing compound. If you can see your way to letting us have some of this material we shall be deeply appreciative. And, by the way, we inadvertently brought away with us the sample containing the two large tungsten rods tied together with two clamps. This will be returned to you immediately. The sample of trinitite which we discussed will be sent to you as soon as it has been mounted.

Again may we express our sincere appreciation and admiration for your efforts in circulating information which is bound to be of great value to the Electronics Industry.

It is to be hoped that you may find it possible to visit New York City in the near future when we shall try to repay in part, if we may, your courtesy and kindness.

With kindest regards,

VLRonci
VICTOR L. RONCI
Vacuum Tube Development Engineer.

Dear Mr. Webb:

For your kind reception a couple of weeks ago I do wish to thank you before it is lost to memory.

Some of the German devices you are exhibiting are ingenious and represent advanced technique. I am conscious of having been technically stimulated by what I saw. It is always difficult to evaluate the effect of an exposure of this kind so subtle is our inspiration and our mode of thought, but the influence cannot help but be beneficial. It is apparent that in calling these developments to the attention of American Industry you are doing a real service, and I for one wish to express my appreciation.

I have just about gouged out my eyes trying to scan down and select the more interesting items in the succession of issues of the "Bibliography of Scientific and Industrial Reports". Doubtless the subject index of these items now being prepared will be a real help in this matter of selection. I am looking forward to studying more fully some of the reports that will be obtained in full by Mr. Blanchard.

With personal best wishes,

Sincerely,

/s/ Lloyd Espenschied

BIOGRAPHY OF

GEORGE CHARLES RICHERT

(COMMUNICATIONS AND TECHNICAL EQUIPMENT)

Birth:
Born in Duquesne, Pennsylvania, January 4, 1904. Moved to Glenshaw, Pennsylvania on January 1, 1929. Moved to 211 Harden Avenue, Duquesne, Pennsylvania, (domicile) on July 1, 1942.

Education:
Attended schools in Duquesne, Pa.; graduated from high school in 1922 and received degree of A.B. from Pennsylvania State College in 1926.

Experience:
From July 1926 to July 1927 employed by Nat'l. Union Fire Insurance Co., Pittsburgh, Pa., in auditing work. From July 1927 to February 1942 employed by Bell Telephone Co. of Pennsylvania, Pittsburgh, Pa. as Commercial Representative, Assistant Division Sales Manager, Manager and Commercial Staff Engineer. During this period attended plan wiring school; analyzed subscriber telephone and teletypewriter service requirements; engineered facilities and equipment to meet such requirements; managed contractual and public relations activities; and estimated line and station growth for central office engineering. From February 1942 to February 1943 was engaged in liquidating and closing parents estate.

Present Employment:
From March 1943 to October 1944 employed by W.P.B., Communications Division as Technical Analyst in the Telephone and Telegraph Sections. Determined action to be taken on applications involving communications company and subscriber facility and equipment requirements, printerization of international submarine cables, and consolidation of Western Union Telegraph Co. and Postal Telegraph & Cable Co. functional offices. From October 1944 to November 1946 employed as Electrical Engineer - Communications by Treasury Department Procurement Division, Public Utilities Division. Prepared and submitted to the Bureau of the Budget, War and Navy Departments, Signal Corps and Federal Works Agency a recommendation involving highly difficult and technical engineering work and covering the establishment of a nation-wide leased-line network to meet the long distance telephone communication requirements of the Federal Government. The establishment of the proposed voice communications network will effect an annual saving to the Federal Government in excess of $300,000.00 Was consulted by various Government activities in Washington, D.C., for the resolution of local telephone and telegraph service engineering problems.

From November 7, 1946 to present employed by Department of Commerce, Office of Technical Services, Technical Industrial Intelligence Division, Electronics and Communications Section as a Technologist, assisting the Chief of the Unit in obtaining information on technical developments in Germany for use by American Industry. Present grade is P-6.

BIOGRAPHY OF

EDWIN Y. WEBB, JR.

(COMMUNICATIONS AND TECHNICAL EQUIPMENT)

Birth: Born in Wake Forest, North Carolina, October 13, 1904, son of Federal Judge Edwin Yates Webb and Willie Simmons Webb. Moved to Shelby, North Carolina at the age of two.

Education: Attended schools in Shelby and Washington, D. C.; graduated from high school in 1922 and received degree of B.S. from Greater University of North Carolina in 1926. Did post-graduate work at the Massachusetts Institute of Technology, 1927-1928. Received professional degree of Electrical Engineer. Member of Tau Beta Pi, honorary engineering fraternity, and graduated "Cum Laude".

Experience: From 1928 to 1944 was employed by the American Telephone and Telegraph Company in Atlanta, Georgia as Program Transmission Supervisor, Transmission Engineer, Planning Engineer and Equipment Engineer. During this period attended and taught numerous technical schools, including those concerning Type J, K and L carrier telephone and telegraph communications, and made numerous technical studies in research and development in communications problems.

Present Employment: Since July 1944 have been on loan from the AT&T Company to the War Production Board, Communications Division, and was Deputy Chief of the Telegraph Section. Became Chief of the Communications Unit of JIOA (Joint Intelligence Objectives Agency), organised under the Joint Chiefs of Staff in September 1945. This Unit was later transferred to the Department of Commerce and is charged with obtaining information on technical developments in Germany for use by American Industry. Am member of the Communications Committee on Standard Commodity Classification, under Executive order of the President. Own two patents covering a new secrecy system for voice communication, which was discussed in a recent issue of Collier's Magazine. Am at present writing a book titled "The Origin of Harmonic Frequencies in Vacuum Tube Circuits." Have owned and operated amateur radio telephone and telegraph station since 1920. This station was described at length in the amateur radio magazine "QST". In a recent issue of "Electronics" magazine, had an article published on "The Design of Dissymmetrical Pads". Present grade is P-7.

VACUUM TUBE DEVELOPMENTS

The discovery of the developments which the Germans had made as a result of wartime research in vacuum tubes used for radio, radar, telephone and telegraph communication purposes will probably prove to be of such value when exploited by domestic manufacturers as to justify many times the cost of all investigation work in the entire electronics and communications field.

German scientists found that by gold-plating the copper leads through the glass envelope of the tube, particles of the metal from the wires would be prevented from spreading microscopically into the glass, as is the case in the normal practice when these wires are sealed at high temperatures into the glass envelope. The insulating properties of the glass envelope are thus increased, thereby vastly improving operation of the tubes. This development is covered in Report No. PB-1638.

Exploitation by American industry of the discovery of the many improvements made by the Germans in the techniques involved in the production of glass envelopes for vacuum tubes will result in inestimable economies in domestic tube manufacture. This is also true of the cheap and simple process developed by Dr. Carl Bosch for applying metal to glass to form vacuum tight seals. Information pertaining to these developments is contained in Report No. PB-17553.

An excellent example of a material developed by the Germans for use in vacuum tube manufacture and unknown to domestic manufacturers is that of a glass soldering compound which will provide American industry with another means of effecting additional economies in vacuum tube manufacture. This will prove particularly beneficial because the use of the glass solder has no effect on the shape of the glass parts being soldered, thus permitting the soldering of the glass preformed vacuum tube base to the glass envelope of the tube. Samples of the glass solder used by the Germans are being evacuated to this country for exploitation by American industry.

Information pertaining to this development also is available in Report No. PB-17553 published by the Office of Technical Services of the Department of Commerce.

See attached letters.

and it was displayed at the Corporation's plant in Chattanooga and the ceramics Industry was invited to attend. The machine was then moved to the plant of the General Ceramics Company at Keasbey, New Jersey, where it is now on display. This dry stamping process is unique and has many advantages, particularly that the stamped part has no shrinkage, whereas in the wet process shrinkage always occured and in an amount which could not be predicted accurately. New ceramics parts made by this process are now being made available to the American market.

5) VACUUM TUBE TECHNIQUES

It is probable that the Germans made more improvements in vacuum tube design than in any other branch of electronics. This was brought about by the pressure of war and these improvements began as early as 1933 but were "Top Secret" and only became known when our investigators went into Germany at the termination of hostilities. Many vacuum tubes were evacuated to this country and disseminated to the vacuum tube companies of the Nation, and as a result, new and improved tubes are already available or are rapidly becoming available. See Sylvania letter attached.

6) X-RAY TUBE DEVELOPMENTS

Likewise, German scientists greatly improved X-ray tubes and techniques. New materials were developed and new techniques evolved which have extended the power and application of X-rays and at the same time reduced the size and voltages required. Office of Technical Services' investigators evacuated numerous complete X-ray installations and made them available to X-ray manufacturers in this country.

7) NEW OPTICAL DEVICES

Due to the requirements of war many new optical instruments were produced in Germany with improvements of associated techniques. New methods of

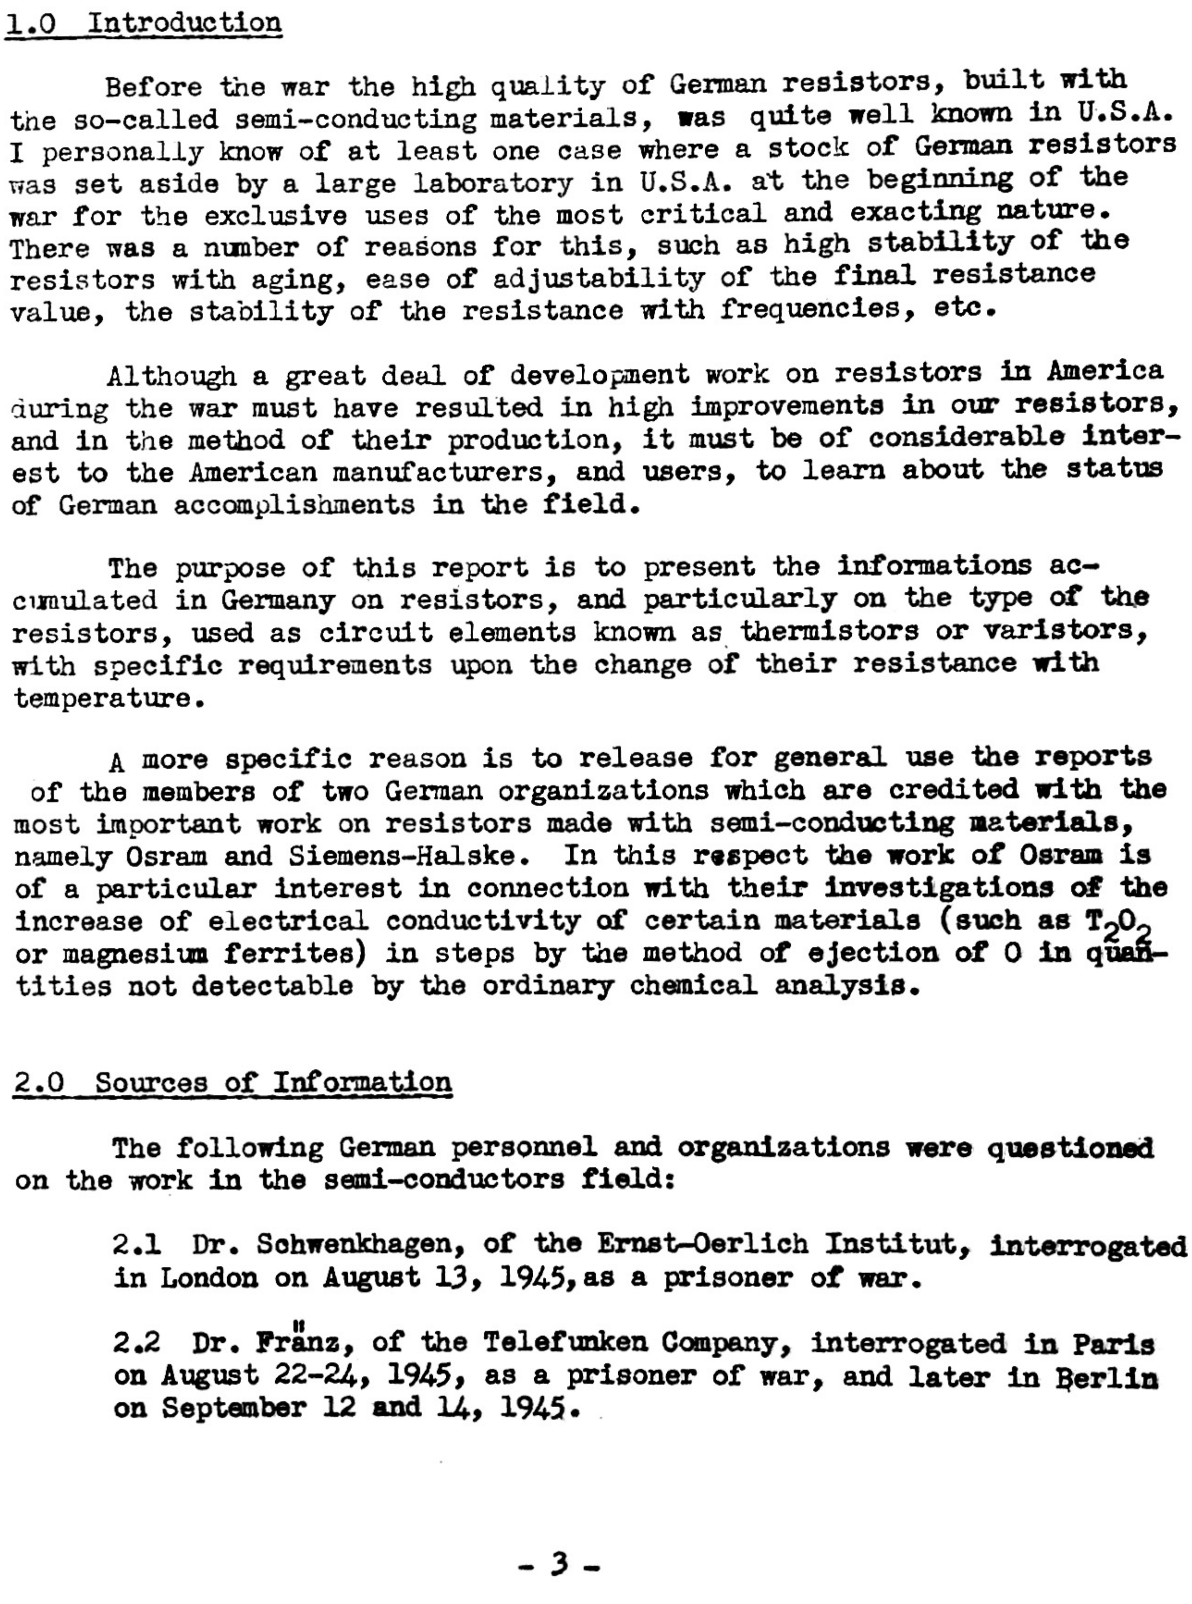
WASHINGTON, D. C.

Figure B.299: Example of archival documents demonstrating the postwar transfer of microelectronics documents, hardware, personnel, and knowledge [FIAT 54]. There was likely a great deal of additional technology transfer that was not recorded in official documents.



1.0 Introduction

Before the war the high quality of German resistors, built with the so-called semi-conducting materials, was quite well known in U.S.A. I personally know of at least one case where a stock of German resistors was set aside by a large laboratory in U.S.A. at the beginning of the war for the exclusive uses of the most critical and exacting nature. There was a number of reasons for this, such as high stability of the resistors with aging, ease of adjustability of the final resistance value, the stability of the resistance with frequencies, etc.

Although a great deal of development work on resistors in America during the war must have resulted in high improvements in our resistors, and in the method of their production, it must be of considerable interest to the American manufacturers, and users, to learn about the status of German accomplishments in the field.

The purpose of this report is to present the informations accumulated in Germany on resistors, and particularly on the type of the resistors, used as circuit elements known as thermistors or varistors, with specific requirements upon the change of their resistance with temperature.

A more specific reason is to release for general use the reports of the members of two German organizations which are credited with the most important work on resistors made with semi-conducting materials, namely Osram and Siemens-Halske. In this respect the work of Osram is of a particular interest in connection with their investigations of the increase of electrical conductivity of certain materials (such as T_2O_2 or magnesium ferrites) in steps by the method of ejection of O in quantities not detectable by the ordinary chemical analysis.

2.0 Sources of Information

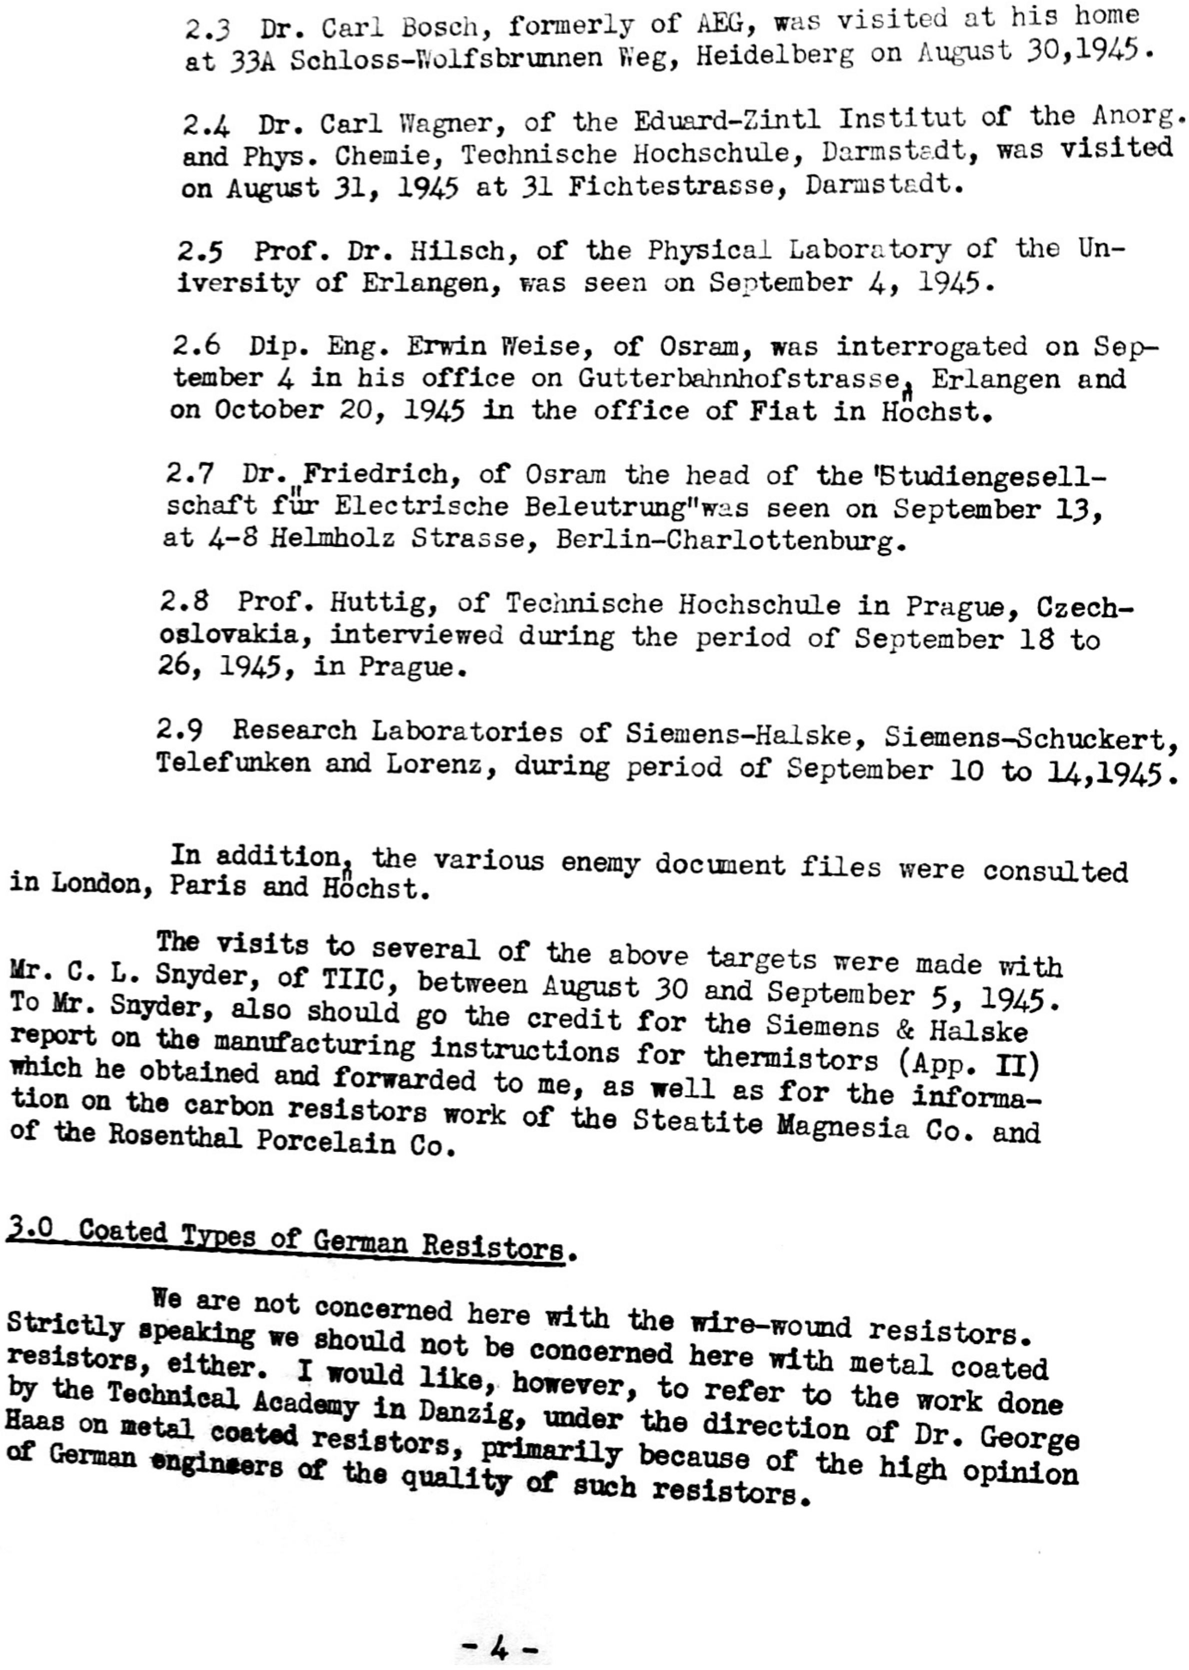
The following German personnel and organizations were questioned on the work in the semi-conductors field:

2.1 Dr. Schwenkhagen, of the Ernst-Oerlich Institut, interrogated in London on August 13, 1945, as a prisoner of war.

2.2 Dr. Fränz, of the Telefunken Company, interrogated in Paris on August 22-24, 1945, as a prisoner of war, and later in Berlin on September 12 and 14, 1945.

- 3 -

Figure B.300: Example of archival documents demonstrating the postwar transfer of microelectronics documents, hardware, personnel, and knowledge [FIAT 54]. There was likely a great deal of additional technology transfer that was not recorded in official documents.



2.3 Dr. Carl Bosch, formerly of AEG, was visited at his home at 33A Schloss-Wolfsbrunnen Weg, Heidelberg on August 30,1945.

2.4 Dr. Carl Wagner, of the Eduard-Zintl Institut of the Anorg. and Phys. Chemie, Technische Hochschule, Darmstadt, was visited on August 31, 1945 at 31 Fichtestrasse, Darmstadt.

2.5 Prof. Dr. Hilsch, of the Physical Laboratory of the University of Erlangen, was seen on September 4, 1945.

2.6 Dip. Eng. Erwin Weise, of Osram, was interrogated on September 4 in his office on Gutterbahnhofstrasse, Erlangen and on October 20, 1945 in the office of Fiat in Höchst.

2.7 Dr. Friedrich, of Osram the head of the "Studiengesellschaft für Electrische Beleutrung" was seen on September 13, at 4-8 Helmholz Strasse, Berlin-Charlottenburg.

2.8 Prof. Huttig, of Technische Hochschule in Prague, Czechoslovakia, interviewed during the period of September 18 to 26, 1945, in Prague.

2.9 Research Laboratories of Siemens-Halske, Siemens-Schuckert, Telefunken and Lorenz, during period of September 10 to 14,1945.

In addition, the various enemy document files were consulted in London, Paris and Höchst.

The visits to several of the above targets were made with Mr. C. L. Snyder, of TIIC, between August 30 and September 5, 1945. To Mr. Snyder, also should go the credit for the Siemens & Halske report on the manufacturing instructions for thermistors (App. II) which he obtained and forwarded to me, as well as for the information on the carbon resistors work of the Steatite Magnesia Co. and of the Rosenthal Porcelain Co.

3.0 Coated Types of German Resistors.

We are not concerned here with the wire-wound resistors. Strictly speaking we should not be concerned here with metal coated resistors, either. I would like, however, to refer to the work done by the Technical Academy in Danzig, under the direction of Dr. George Haas on metal coated resistors, primarily because of the high opinion of German engineers of the quality of such resistors.

REPLYING TO

MR. E. Y. WEBB,
Department of Commerce,
Room 2097,
14th & E Streets, N.W.,
Washington, D. C.

Dear Mr. Webb:

During my trip to Germany in 1945, I brought back with me several telephone transmitters and a telephone handset. Our Transmission Department has made transmission measurements of these instruments. I thought this information might form a valuable part of your record in Washington and consequently I am sending you two Memoranda for File on this subject; one dated December 19, 1945 and the other December 26, 1946.

I am also pleased to send you, herewith, a photostat copy of a German article "Measuring Devices for Recording the Distribution of Current and Voltage on Antennas" by F. M. Daser. Our Technical Library has translated this article and I am sending it along as an item of interest. Photostatic copies of this article have been available through your office for some time but I do not know of the availability of a first class translation.

Sincerely yours,

J R Townsend

J. R. TOWNSEND

MR. JOHN C. GREEN, Director
Office of Technical Services
Department of Commerce
Washington 25, D. C.

Dear Mr. Green:

You will be interested to know that the Laboratories has acquired a considerable amount of valuable information as a result of its contacts with the Office of Technical Services which were instituted last summer. This is in no small measure due to the friendly and cooperative attitude which we have encountered in our relations with your Office and for which we are most appreciative.

We plan to continue sending Dr. Blanchard to Washington, as a representative of the Western Electric Company as well as the Laboratories, where he will keep in touch with the literature that is coming from abroad as well as from various sources in this country. He has found the Office of Technical Services very helpful in his search for reports on subjects which are of special interest to the Western Electric Company and to the Laboratories.

It appears to us that your organization is proceeding most competently with the accomplishment of its objectives and we wish you further success in this program which is of such significance to American industry.

Very truly yours,

/s/ O. E. Buckley
President

DEPT OF COMMERCE OFFICE OF TECHNICAL SERVICES 1947 MAY 5 PM 4 07

MAY 5 1947

29 April 1947

Memorandum for Returned Investigators of German Industry

The investigations of German industry conducted under the auspices of the Technical Industrial Intelligence Committee, the Technical Industrial Intelligence Branch and the Technical Industrial Intelligence Division are ending 30 June 1947. In this connection there are two respects in which your assistance would be of great value to us.

1. From our contacts with returned investigators, we understand that some brought back to the United States documentary data in the form of German reports, catalogues, specifications and drawings to which references appeared, in some cases, in their final reports. The purpose in taking this material was to use it in preparing supplements to their original reports or new reports based on studies of these technical data.

Accordingly, some investigators have returned such material to this office with covering technical reports that have subsequently been published by the Department of Commerce. However, we feel that there must still be some technical material in the possession of other investigators which they have not had the time to review because of the pressure of private responsibilities. Therefore, if you still have retained in your files any such documents, would you please return them to this office as soon as possible, so we can make them available to the interested American public. If you have no such material acknowledgement to that effect would be appreciated.

2. Attached is a copy of an article "Compendium of German Technology" from the 14 April 1947 issue of Chemical and Engineering News that you may find of interest. This office is now bringing to this country large quantities of German language technical data on microfilm which it will be glad to make available to returned investigators without cost if they state their special fields of interest, and if they agree to prepare an English language report upon it. We would be pleased to hear from returned investigators in this respect.

Mr. E. Bruce
Bell Telephone Laboratories, Inc.
463 West Street
New York 14, New York

My dear Mr. Bruce:

In answer to your letter of the 27th of June 1946 in which you requested information on lead sulfide photo-electric cells, I sent you on the 2nd of July 1946 a cell which had been removed from a light-beam transmitter. In my letter I requested that you submit to this office a copy of your report on the results of your research. To date I have had no reply to my letter.

I hope that you have obtained worth while information from this cell and would like to hear from you concerning your results. Please furnish me with details of your report or any information which you may have available on it.

I have recently obtained more of these cells which I am delivering to Dr. Julian Blanchard of the Laboratories.

Sincerely yours,

Edwin Y. Webb, Jr.
Chief, Electronics and
Communications Section
Technical Equipment Section

Authority NND 968148

NARA RG 40, Entry UD-75, Box 58, Folder Webb

Mr. O. W. Holloway 29 April 1948

Edwin Y. Webb

As you know two representatives of the Signal Corp, Mr. Kaprillian, Chief of the Optical Division, and his assistant Dr. Keck, spent Monday, Tuesday and Wednesday opening and examining the contents of the trunks and documents stored at 15 Canal Street. So far, they have examined and labeled approximately 800 trunks. They were extremely complimentary of the cooperation given them by Mr. Sherwin and the men he assigned to assist.

Mr. Kaprillian and Dr. Keck have now returned to Fort Monmouth but will continue their work here next week and the week following. Mr. Kaprillian states that he believes the material contained in these trunks is worth $100,000,000 and so far the one or two dozen trunks of optics material, which he has discovered, will save the Signal Corp $30,000 in research and development. One trunk which they opened containing microfilm reels is believed to be a copy of all documents in these trunks. Mr. Kaprillian will write a letter of thanks to the Office of Technical Services for the assistance and cooperation which he has been given.

I should like to have your acquiescence to permitting the Signal Corp to transport to Fort Monmouth, via Army Truck, the several trunks of optics material. The documents will then be examined in minute detail, copied and important ones translated, and a copy of all translations will be furnished The Office of Technical Services for publication and distribution. All documents will then be returned to 15 Canal Street at Signal Corp expense.

Florian Metzler. 2020. The Transistor, an Emerging Invention: Bell Labs as a Systems Integrator Rather Than a 'House of Magic.' p. 33. https://ssrn.com/abstract=3678081

Karl Darrows, trained as a PhD physicist and a speaker of multiple languages, maintained personal relationships with a large number of leading academic physicists in Europe and the United States. European-trained researchers fulfilled similar tasks such as Foster Nix who received his graduate training in Berlin and was bilingual in English and German (Nix 1975). Relevant scientific news that Bell Labs employees such as Darrows and colleagues might have missed, were often brought to their attention by collaborators in Bell Labs' extended network. An example is Karl Lark-Horovitz, physics department head at Purdue and an Austrian immigrant, who regularly monitored German-language publications and drew attention to relevant new developments in interactions with Bell Labs collaborators (Van Dormael 2004).

Michael Eckert and Helmut Schubert. 1990. *Crystals, Electrons, Transistors: From Scholar's Study to Industrial Research.* pp. 158–163, 166

Bell Laboratories' research director Kelly was giving particular attention to applications in the field of radio for commercial exploitation after the war, once the field of microwaves and radio waves had been opened up to his organization through the radar project. [...] The physical research division was reorganized in July 1945 in order to give more emphasis to solid-state physics. [...]

Shockley, who returned to Bell Laboratories from his war service at the Pentagon in 1945, took charge of the semiconductor group as a theoretical solid-state physicist. The rest of this group consisted of the experimental physicist Brattain, who had been studying the properties of semiconductive surfaces since 1931; Pearson, also an experimental physicist, who had spent many years studying the interior properties of semiconductors; Hilbert Moore, a specialist in electronic circuits; and Robert Gibney, an expert in physical chemistry. To round out his team Shockley suggested to his superior Mr. Kelly that a position be offered to John Bardeen. Bardeen had earned his doctorate at Princeton under Wigner and had worked with van Vleck at Harvard, where Shockley had met him. Both Wigner and van Vleck were among the leading theoreticians in the field of solid-state physics. The general charter of the newly formed group called for the development of fundamental knowledge on the properties of semiconductors, but everyone had "in the back of his mind the objective of building an amplifier out of semiconductive material."

The semiconductor group at Bell Laboratories began its work with a survey of wartime developments in the field of semiconductors in their own research laboratories and those of others. [...]

Shockley could not patent the idea [of a field effect transistor], however, since Julius Lilienfeld had applied for a patent in 1926 on a very similar process, which, however, was never put to practical use. The experiments, however, in which Brattain collaborated, could not demonstrate the predicted effect. [...]

A decisive series of experiments began in November 1947. [...] On November 23, 1947, Bardeen wrote in his laboratory notebook that it was possible to amplify the flow of current from the electron-conducting layer into the metal wire tip by applying a voltage between the drop and the block of silicon. But no change occurred in the voltage between the block and the wire tip. This design, of course, was still entirely unsuitable for practical application. The drop of water evaporated quickly and only slowly changing currents were amplified. [...]

The further experiments in December 1947 were concentrated on the point contact. Bardeen reckoned that a significant amplification would be achieved when the contacts were spaced only some 0.05 mm apart. At that time this was a very difficult problem, which Brattain solved elegantly. He applied gold foil to a three-dimensional prism and cut it on one side of the triangle carefully with a razor blade in order to obtain two closely spaced contacts. This arrangement worked on the first try on December 16, 1947. It amplified signals up to 100 times, and amplification occurred even at frequencies in the radio wave region. A step had been made toward Kelly's research objective in the 1930s, the development of a practical solid-state repeater. A week of intensive work followed to make sure that no errors crept in. On December 23, 1947, the amplifier was shown to management. [...]

When the first germanium point-contact transistors were produced on an industrial scale in 1951 by Western Electric, the manufacturing arm of the Bell System, several other large firms were experimenting with the new component. It turned out to be difficult to build reliable transistors with the two closely space points, and it was almost impossible to produce them with identical characteristics. They had a very limited lifetime and could not process high-frequency currents. Compared with equivalent technical data for amplifier tubes, these transistors were not attractive products.

Jon Gertner. 2012. *The Idea Factory: Bell Labs and the Great Age of American Innovation.* pp. 90–92.

“My calculations showed that very substantial modulation of the resistance should occur,” Shockley later noted. “None was observed. On 23 June 1945, I wrote that the effects were at least 1,500 times smaller than what I predicted should have been observable.” He was vexed. And for close to a year, any attempts to make the field effect work failed. Shockley would eventually call this period “the natural blundering process of finding one’s way.”

Whatever it was, by January 1946 the solid-state group, venturing far beyond the traditional methods of trial-and-error invention, had found neither enlightenment nor promise. As Brattain’s lab mate Gerald Pearson would later note, they were groping in the dark. [...]

Shockley and Bardeen had even spent several weeks together in the summer of 1947 visiting various European laboratories. By late autumn, with the newly planted trees on the Murray Hill campus nearly bereft of leaves, the solid-state team began an experimental regimen on silicon and germanium slices that offered a steady progression of insights.

Lillian Hoddeson and Vicki Daitch. 2002. *True Genius: The Life and Science on John Bardeen.* pp. 128–131.

The group tried many related experiments, but for the next eighteen months they made little progress.

During the remainder of 1946 and throughout 1947, Shockley’s engagement with the field effect studies flagged, for he developed new interests during the summer of 1947, when he and Bardeen took an extended tour of European laboratories. [...]

Bardeen wrote that he had “learned a lot during the trip, and have picked up some information that may be useful to the Lab. Whether or not it’s enough to pay for the trip is hard to judge.” In any case, it had been “very hard work—much harder than you can imagine without doing it—but it’s also been a grand experience.” [...]

The “magic month” that culminated in the transistor began in the middle of November 1947, three months after Bardeen and Shockley returned from Europe.

Werner Grothmann (Heinrich Himmler's adjutant) [Krotzky 2002, p. 48]. For a discussion of the background and reliability of this source, see pp. 3396–3397.

Entweder steuert jemand die Rakete ins Ziel, oder die muß vollautomatisch gehen. Himmler war skeptisch, ob ein Pilot bei der Geschwindigkeit überhaupt reagieren kann. Ich meine, die Rakete sollte ja mit etlichen Tausend Kilometern fliegen. Dann gab es auch gar keine Fernsteuerung, die auf die Entfernung wirklich sicher funktionierte. Da hatte Himmler schon früher mal mit Ohnesorge darüber gesprochen und ich glaube, der hat dazu auch was arbeiten lassen. Was sich da ergeben hat, weiß ich aber nicht. Nur an eines kann ich mich noch erinnern, nämlich unsere Raketenleute hatten ja eine kleine Abteilung von, heute müsste sagen Elektronikern, die haben zur völligen Überraschung von uns und auch von Ohnesorge im Winter 44 eine Sende- und Empfangsanlage entwickelt, die man nicht mehr stören konnte, weil sie selbständig dauernd die Funkfrequenz änderte. Außerdem war die ganz klein, richtig winzig. Die hatte nur ungefähr ein kg, der Empfänger meine ich. Wie die das geschafft haben, diese Technik zu verkleinem, ist mir unbekannt. Himmler aber Befehl gegeben, Ohnesorge den Prototyp zu zeigen. Ob das geschehen ist, kann ich nicht sagen. Ich weiß auch nicht, ob der Sender überhaupt auf die Reichweite bis Amerika ausgelegt war. Nach Krieg hörten wir dann, die Amerikaner hätten den Transistor erfunden. Das hat wohl einige von unseren Leuten sehr aufgeregt, weil der doch von uns stammte. Ein Bekannter sagte mir dazu, bei uns hätte der Transistor "Sperrschicht-Halbleiter" geheißen. Der war von einem Professor an einer technischen Hochschule erfunden worden. Es kann sein das war Aachen.

Either someone pilots the rocket into the target, or it must be fully automatic. Himmler was skeptical whether a pilot could react at all at that speed. I mean, the rocket was supposed to fly several thousand kilometers. Then there was no remote control at all, which really worked safely at that distance. Himmler had already talked to Ohnesorge about this and I think he had something worked out. But I don't know what came of it. I can only remember one thing, namely that our rocket people had a small department of, today I would have to say electronic engineers, who, to the complete surprise of us and also of Ohnesorge, developed a transmitting and receiving system in the winter of 44, which could no longer be jammed, because it constantly changed the radio frequency on its own. It was also very small, really tiny. It weighed only about one kilogram, the receiver I mean. How they managed to miniaturize this technology is unknown to me. But Himmler gave orders to show the prototype to Ohnesorge. Whether this was done, I cannot say. I also don't know if the transmitter was even designed to reach America. After the war, we heard that the Americans had invented the transistor. That must have upset some of our people very much, because it came from us. An acquaintance told me that in our country the transistor was called a "junction semiconductor." It had been invented by a professor at a technical university. It may have been Aachen.

[For other sources that confirmed that highly advanced electronic guidance systems for long-range missiles were developed in Germany during the war and then transferred after the war to the United States, specifically AT&T Bell Laboratories, see for example pp. 2938–2962, 5348, 5444, 5454, 5557.

Evidence such as that presented in this appendix suggests (but does not yet prove—much more investigation is required) that the German-speaking scientists' transistor developments not only preceded those of Bell Laboratories, but may have been directly used by Bell Laboratories as a guide to reproduce the earlier German-speaking work:

- The German-speaking transistor developments came from at least 12 different groups doing extensive work during a period of over two decades collectively.

- During World War II, the German military was keenly interested in funding the development of smaller, more rugged, and more sophisticated electronic guidance systems that could be used in rockets ranging from anti-aircraft missiles to intercontinental ballistic missiles. Transistors derived from the existing German patents and papers would have been an important part of those guidance systems.

- In spring 1945, hundreds of thousands of tons of German-language technical documents were seized by the United States, thousands of German-speaking scientists were interrogated by U.S. scientists and engineers, and countless prototypes, pieces of equipment, and whole laboratories were shipped to the United States.

- Personnel from Bell Laboratories played a prominent role in collecting that scientific information from Europe and processing it in the United States.

- In late 1945, Bell Laboratories put John Bardeen and Walter Brattain to work to try to produce a simple transistor, with some supervision by William Shockley. As noted above, “the semiconductor group at Bell Laboratories began its work with a survey of wartime developments in the field of semiconductors.”

- Bardeen and Shockley conducted detailed visits to numerous European laboratories from June through August 1947. During that time, Bardeen or Shockley could have easily encountered scientists, reports, or information from the earlier transistor development programs of the German-speaking world, or at least Allied investigators who had already studied those programs. Although any transistor-related information that Bardeen and Shockley learned during this time has never been publicly disclosed, Bardeen wrote at the end of the trip: “learned a lot during the trip, and have picked up some information that may be useful to the Lab” [Hoddeson and Daitch 2002, p. 130].

- Bardeen and Brattain did not begin serious experimentation with transistor-like devices until November 1947, two and a half years after the end of the war (and over two and a half years after the collection and study of German microelectronics information began in earnest). Within just a couple of months this very small team created what appears to be a crude replica of the earlier German work.

- Not only did Shockley not give any credit to the earlier German work, but he refused to give proper credit to Bardeen and Brattain, who actually performed the Bell Laboratories experiments.

- Due to their personal differences, the team of Bardeen, Brattain, and Shockley soon split up. Even in 1951, Western Electric (the manufacturing arm of AT&T/Bell Laboratories) was unable to produce reliable transistors. Most transistor development in the United States was carried out by other researchers, including several German-speaking scientists (Kurt Lehovec, Herbert Kroemer, Jean Hoerni, Eugene Kleiner, Karl Heinz Zaininger, etc.) as shown in this appendix.

Much more archival research is needed to determine the true extent of microelectronics innovations in the German-speaking world, as well as how much that influenced postwar work in other countries.]

Appendix C

Advanced Creations in Directed Energy

> In hoc templo, quod totum ex auro paratum est, statuas trium deorum veneratur populus, ita ut potentissimus eorum Thor in medio solium habeat triclinio. [...] ‘Thor’, inquiunt, ‘praesidet in aere, qui tonitrus et fulmina, ventos ymbresque, serena et fruges gubernat.’ [...] Thor autem cum sceptro Iovem simulare videtur.

> In this temple, entirely decked out in gold, it is said, the people worship the statues of three gods, so that the mightiest of them, Thor, occupies a throne in the middle of the chamber. [...] ‘Thor,’ they say, ‘rules the sky; he governs thunder and lightning, winds and storms, fine weather and crops.’ [...] Thor with his scepter apparently resembles Jupiter.

Adam of Bremen. Circa 1075. *Gesta Hammaburgensis Ecclesiae Pontificum*
[*Deeds of the Bishops of Hamburg*]. Book 4 (Descriptio insularum Aquilonis), Chapter 26.

This appendix presents evidence for early German research and development regarding various types of directed energy technologies, such as:

C.1. Particle beams and X-rays.

C.2. Electromagnetic pulse weapons.

C.3. Lasers.

C.4. Focused sound waves.

C.5. Electromagnetic railguns.

Although this evidence is relatively brief and highly incomplete, hopefully it will stimulate much more archival research in the future in order to elucidate the complete work of German-speaking scientists in these areas, as well as the full impact that their work had on later scientists and projects outside the German-speaking world.

C.1 Particle Beams and X-Rays

[German-speaking scientists did an enormous amount of work on particle accelerators before and during the war. Some of that work was simply aimed at developing the relevant technologies or applying them to fundamental physics questions. A significant amount of the work was for nuclear physics, apparently even including electronuclear breeding of weapons-grade fission fuel (see pp. 3954–4022, 4504–4510, and 5133–5134). Yet much of the work on particle accelerators seems to have been intended to create directed energy weapons. Many different versions of such weapons were under development during the war; they would have fired a beam of high-energy electrons and/or ions, or in some cases they would have harnessed the energy from those charged particles to produce an intense beam of X-rays, a burst of high-energy neutrons, or other forms of radiation. If some of the reports available in archives are correct (and one could certainly debate whether they are, unless or until more conclusive evidence is found), at least some of these weapons apparently reached the stage of successful tests against laboratory animals or solid targets.

The known amount of literature on this topic is quite large, so this section can only present some highlights. Even so, much more archival research should be conducted to unearth new information on these programs, in order to determine exactly how far they progressed and how much they influenced programs in other countries.

All accelerators use an electric field to accelerate charged particles. However, different types of accelerators produce the electric field in different ways, accelerate particles either continuously or by a series of impulses, and employ either circular or linear geometries:

- In a betatron, electrons follow a circular orbit in a magnetic field. Changing the magnetic flux passing through the orbit induces an accelerating electric field around the orbit. The increasing magnetic field keeps the orbital radius constant despite the increasing particle energies. The iron pole pieces are shaped to provide a stronger magnetic field inside the orbit than at the orbital radius.

- In a cyclotron, an accelerating electric field is applied each time the particles pass between two D-shaped electrodes. Particles are allowed to spiral outward as their energy increases.

- In a synchrotron, an accelerating electric field is applied each time the particles cross an electrode gap. Magnetic sections bend the particle trajectories into a closed orbit. Straight, magnetic-field-free sections are useful for injecting or extracting particles. By allowing a large orbital radius and adjusting the electric and magnetic fields as particles are accelerated, energies of > 1 TeV can be obtained.

- In a linear accelerator, particles travel down the center of a long, straight tube. There is a traveling or standing electromagnetic wave in the tube, and a series of irises in the tube makes the wave ricochet back and forth off the walls instead of passing straight down the tube. The ricocheting slows the wave's longitudinal velocity to match the particle velocity and also makes the wave have an electric field component in the longitudinal direction, suitable for accelerating the particles.]

Pedro Waloschek. 2012. *Death-Rays as Life-Savers in the Third Reich.* Draft English translation of *Todesstrahlen als Lebensretter* pp. 98–100 [http://www-library.desy.de/preparch/books/death-rays.pdf].

Rolf Wideröe was born on July 11, 1902 in Oslo where he also went to school. His father was a well situated importer of wine, cognac and oils. His mother was of German origin. After getting his A-levels ("Abitur") in 1920 he started studying electrical engineering at the Technical University in Karlsruhe. Already as a student he had quite original ideas, like i.e. a device which could accelerate electrons to very high energies. Such electrons could be used to investigate the structure of atoms (he admired Lord Rutherford's discoveries). His accelerator should work on the principle of the well known electric current transformer. The secondary windings of the transformer would be substituted with an electron beam turning around in an evacuated tube [Wi23]. So he called his accelerator "beam transformer" or "ray transformer" ("Strahlentransformator").

But Wideröe's beam-transformer did not work. Later on he understood why. Therefore he could not use it for his doctoral thesis. So he built another particle accelerator, this time with positive result. He applied an idea of the Swedish physicist Gustav Ising which consisted in using an available high voltage several times to accelerate the same particles.

With 25,000 Volt available he was able to accelerate particles as if he would have 50,000 Volts! This device was worldwide the first successfully running "linear accelerator" and is considered as an important pioneer achievement in the field.

Wideröe's report on his results was accepted as doctoral thesis and published in a well known journal edited by Rogowski, the "Archiv für Elektrotechnik". As an appendix he added his ideas about a beam-transformer and described an important condition which the used magnet should satisfy. This was later on known as the "Wideröe 2 to 1" condition.

The American physicist Ernest Orlando Lawrence (1901–1958) saw Wideröe's publication in the Library of his Institute, could not understand much of the German texts, but very well the included illustrations. This inspired him to an interesting idea. The principle of the linear accelerator could be used several times on the same particles, if their orbit would be would up with the help of a magnetic field. This was the starting idea for the famous "cyclotron", which in the following years became one of the most important instruments for nuclear physics research. For the development of the cyclotron Lawrence was awarded in 1939 the Nobel Prize in physics. He always acknowledged thankfully Wideröe's initial suggestion [La31]. A curiosity: The cyclotron-principle was at about the same time also presented in their institutes by two German physicists, Eugen Flegler and Max Steenbeck. To my knowledge Flegler never published his ideas and Steenbeck did so, but much too late.

V. Zusammenfassung.

I. Einleitung.

Schwierigkeiten in der Beherrschung hoher Spannungen.

Bekanntlich liegen alle Schwierigkeiten bei der Herstellung hoher Spannungen in der Beherrschung der elektrostatischen Felder. Alle technischen Isoliermaterialien haben eine begrenzte Isolierfähigkeit, bei einer gewissen Feldstärke schlagen sie durch und werden leitend. Die Höhe der erzeugten Spannung wird deswegen hauptsächlich durch die stark zunehmenden Dimensionen der Isolierung begrenzt.

Es besteht nun aber die Möglichkeit, diese Grenze der erzeugten Spannungen wesentlich zu erhöhen, indem man elektrostatische Felder weitgehend vermeidet und die Hochtransformierung mit Hilfe schnellbewegten Elektronen und Ionen vornimmt.

Potentielle und kinetische Spannungen.

Wenn sich elektrische Ladungen durch ein elektrisches Feld bewegen, speichern sie einen Teil der Feldenergie als kinetische Energie auf. Für die kinetische Energie gilt das allgemeine Gesetz, daß sie immer mit der potentiellen Energie verknüpft ist, im Entstehen und im Verschwinden.

Entsprechend dieser Tatsache erscheint es deswegen auch zweckmäßig, von der Spannung einer bewegten Ladung zu reden. Die Ladung erhält dann (in Analogie zu den Energiebegriffen) diese kinetische Spannung, wenn sie durch eine entsprechende potentielle Spannung gefallen ist.

Zwei Wege der Spannungserzeugung.

Bei der Herstellung hoher potentieller Spannungen ist man hauptsächlich zwei Wege gegangen.

Pedro Waloschek. 2012. *Death-Rays as Life-Savers in the Third Reich.* Draft English translation of *Todesstrahlen als Lebensretter* p. 175 [http://www-library.desy.de/preparch/books/death-rays.pdf].

Already in 1927/28 Steenbeck had developed the basic ideas for an accelerator which corresponded exactly to the "Cyclotron" proposed in 1931 by Lawrence. And he also sketched the first ideas for a later on called "Synchrocyclotron". Encouraged by his colleagues at Siemens he wrote all this down in a report which he wanted to publish in the journal "Naturwissenschaften". Due to a misunderstanding with his boss Rüdeneberg (who had asked him for a discussion of his ideas) the paper was never published.

In 1934 Steenbeck had already seen the PhD-thesis published in 1928 by Wideröe and included in his patents the conclusions to which Wideröe had arrived. Wideröe had also tried to submit his ideas as patents in 1929 but did not care about it in the following years, as he was working on a completely different subject (relays).

Max Steenbeck. German Patent DE 698,867. Vorrichtung zur Erzeugung von Elektronen hoher Energie durch das elektrische Wirbelfeld eines sich zeitlich aendernden magnetischen Hauptfeldes. [Device for Generating High Energy Electrons by the Electric Vortex Field of a Time-Varying Main Magnetic Field.] Filed 1935.

[Building on Rolf Wideröe's earliest ideas, Max Steenbeck (German, 1904–1981) invented the first practical betatron (circular particle accelerator for electrons) in 1935. Please see his first betatron patent, German Patent DE 698,867, on the following pages.

Steenbeck obtained similar patents in many other countries, including U.S. Patent 2,103,303, which was issued in 1937. Using the detailed designs in Steenbeck's patents, Donald Kerst copied Steenbeck's device and built the first U.S. circular accelerator for electrons in 1940. Kerst's only original contribution was to rename the device as the "betatron," and the name stuck. (German-speaking scientists seemed to prefer the name "rheotron" in the early years.) Kerst then became widely and incorrectly known as the "inventor" of the betatron while Steenbeck remained virtually unknown.

Some of Steenbeck's experimental results with betatrons were published as:

> Max Steenbeck. 1943. Beschleunigung von Elektronen durch elektrische Wirbelfelder. *Die Naturwissenschaften* 31: 234–235.

From official histories, it is unclear exactly what Steenbeck did during the war, but it seems likely that he worked on the German nuclear weapons program. After the war he spent ten years helping to develop and run major parts of the Soviet nuclear weapons program. He wrote about some of his experiences in his autobiography:

> Max Steenbeck. 1980. *Impulse und Wirkungen.* 3rd ed. Berlin: Verlag der Nation.

Siemens-Schuckertwerke Akt.-Ges. in Berlin-Siemensstadt*)

Vorrichtung zur Erzeugung von Elektronen hoher Energie durch das elektrische Wirbelfeld eines sich zeitlich ändernden magnetischen Hauptfeldes

Patentiert im Deutschen Reiche vom 7. März 1935 ab

Patenterteilung bekanntgemacht am 17. Oktober 1940

Der Erfindung liegt die Aufgabe zugrunde, mit möglichst einfachen technischen Mitteln, vor allen Dingen ohne Anwendung hoher Spannungen, Elektronenstrahlen hoher Energie, beispielsweise Strahlen mit einer Geschwindigkeit von mehreren Millionen Volt zu erzeugen.

Es ist vorgeschlagen worden, zu diesem Zweck ein magnetisches Wechselfeld zu verwenden, durch das ein elektrisches Wirbelfeld erzeugt wird, welches dem Elektron die notwendige Geschwindigkeit erteilt. Die Anordnung ist dabei so getroffen, daß die Elektronenbahn das magnetische Feld umschließt wie die Windungen der Sekundärwicklung eines Transformators den Transformatorkern und damit den diesen Kern durchsetzenden Fluß.

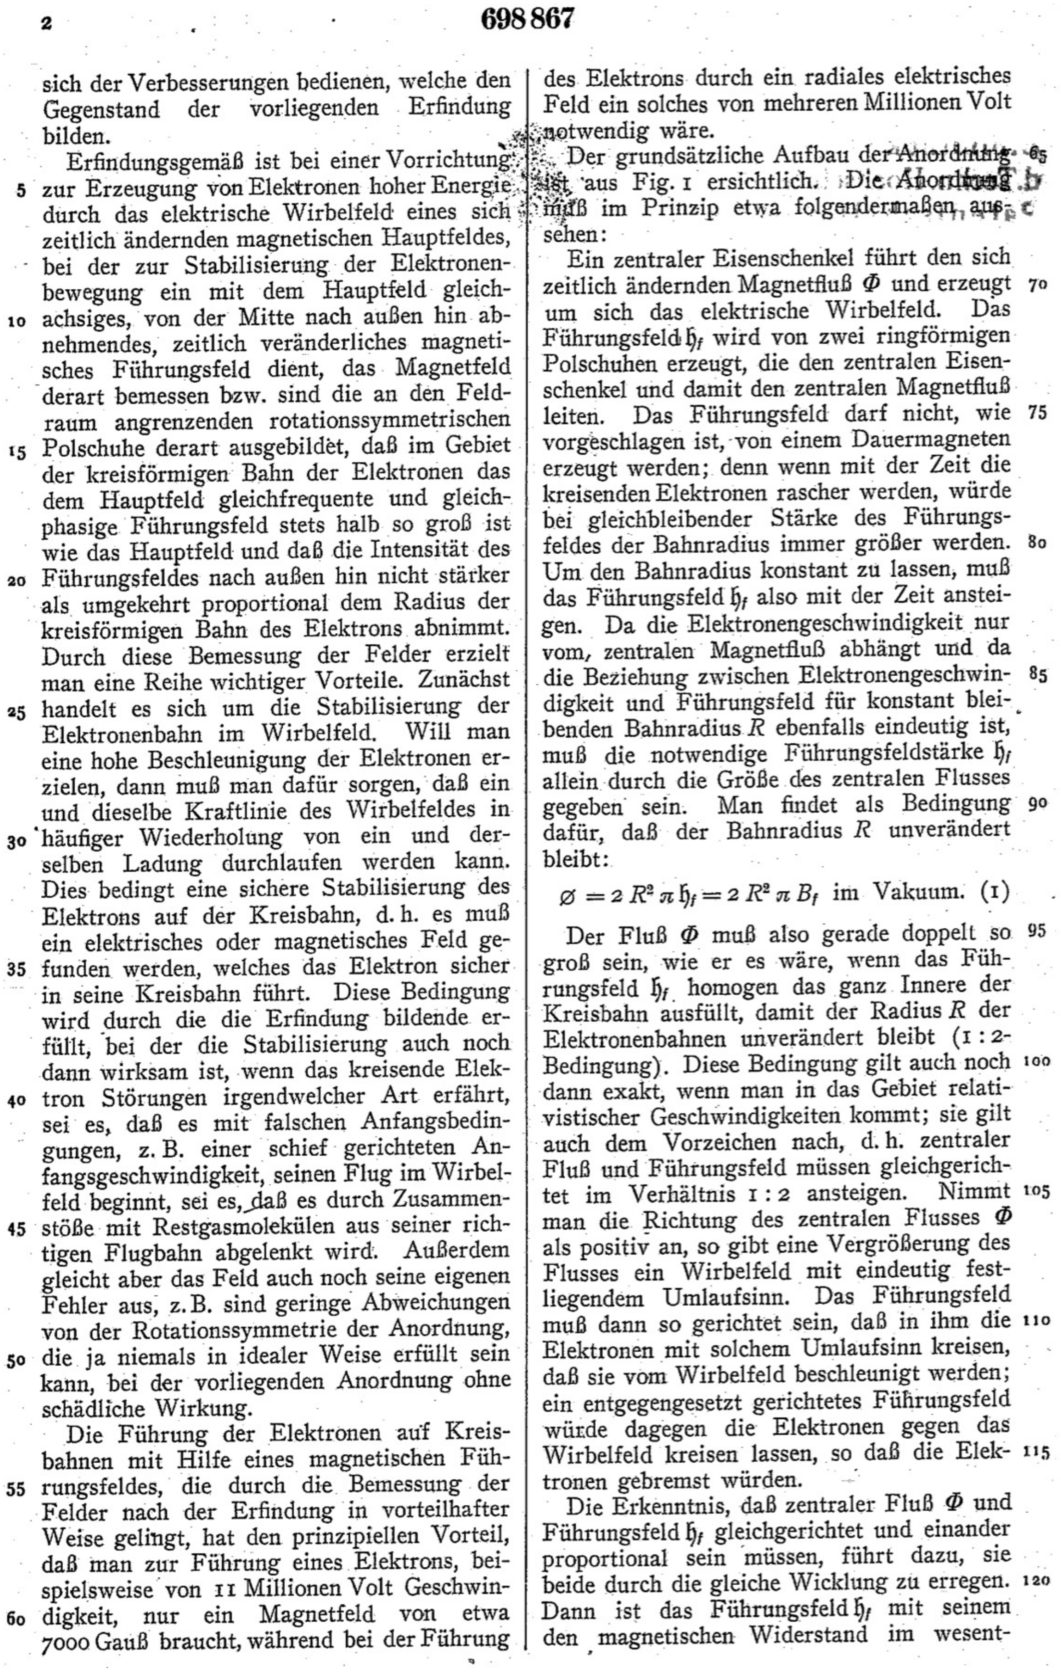
Bei einer bekannten Anordnung dieser Art umschließt ein ringförmiges hochevakuiertes Entladungsgefäß den Kern eines dreischenkligen Transformators, dessen mittlerer Kern eine an technische Wechselspannung üblicher Spannung und Frequenz angeschlossene Erregerwicklung trägt. In dem Entladungsgefäß ist eine Glühkathode angeordnet, welche die für die Strahlung notwendigen Elektronen aussendet. Außer dem Wechselfeld wirkt auf die Elektronen noch ein zusätzliches, von Dauermagneten erzeugtes Magnetfeld, welches dazu dienen soll, die um den Transformatorkern kreisenden Elektronen in einer bestimmten, durch das Entladungsgefäß gegebenen Ebene zu halten, d. h. zu verhindern, daß die Elektronen an irgendeiner Stelle auf die Gefäßwandung auftreffen.

Es ist auch schon vorgeschlagen worden, zur Beschleunigung und Führung der Elektronen bei einer Anordnung zur Herstellung von Röntgenstrahlen ein Magnetfeld zu verwenden, welches von der Mitte nach dem Rande hin abfällt. Dabei ist der Körper, der durch das Auftreffen schnell fliegender Elektronen zum Aussenden von Röntgenstrahlen angeregt werden soll, in der Mitte des Magnetfeldes angeordnet.

Diese bekannten bzw. vorgeschlagenen Anordnungen sind zwar im Prinzip brauchbar, doch geben sie entweder eine verhältnismäßig geringe Ausbeute an schnellen Elektronen, oder sie sind für den vorliegenden Zweck der Erzeugung sehr rascher Elektronen nicht besonders geeignet. Um praktisch wirklich brauchbare Ergebnisse zu erzielen, muß man

*) *Von dem Patentsucher ist als der Erfinder angegeben worden:*
Dr. phil. Max Steenbeck in Berlin-Siemensstadt.

Figure C.14: Max Steenbeck's first patent on betatrons (DE 698,867), filed in 1935.



sich der Verbesserungen bedienen, welche den Gegenstand der vorliegenden Erfindung bilden.

Erfindungsgemäß ist bei einer Vorrichtung zur Erzeugung von Elektronen hoher Energie durch das elektrische Wirbelfeld eines sich zeitlich ändernden magnetischen Hauptfeldes, bei der zur Stabilisierung der Elektronenbewegung ein mit dem Hauptfeld gleichachsiges, von der Mitte nach außen hin abnehmendes, zeitlich veränderliches magnetisches Führungsfeld dient, das Magnetfeld derart bemessen bzw. sind die an den Feldraum angrenzenden rotationssymmetrischen Polschuhe derart ausgebildet, daß im Gebiet der kreisförmigen Bahn der Elektronen das dem Hauptfeld gleichfrequente und gleichphasige Führungsfeld stets halb so groß ist wie das Hauptfeld und daß die Intensität des Führungsfeldes nach außen hin nicht stärker als umgekehrt proportional dem Radius der kreisförmigen Bahn des Elektrons abnimmt. Durch diese Bemessung der Felder erzielt man eine Reihe wichtiger Vorteile. Zunächst handelt es sich um die Stabilisierung der Elektronenbahn im Wirbelfeld. Will man eine hohe Beschleunigung der Elektronen erzielen, dann muß man dafür sorgen, daß ein und dieselbe Kraftlinie des Wirbelfeldes in häufiger Wiederholung von ein und derselben Ladung durchlaufen werden kann. Dies bedingt eine sichere Stabilisierung des Elektrons auf der Kreisbahn, d. h. es muß ein elektrisches oder magnetisches Feld gefunden werden, welches das Elektron sicher in seine Kreisbahn führt. Diese Bedingung wird durch die die Erfindung bildende erfüllt, bei der die Stabilisierung auch noch dann wirksam ist, wenn das kreisende Elektron Störungen irgendwelcher Art erfährt, sei es, daß es mit falschen Anfangsbedingungen, z. B. einer schief gerichteten Anfangsgeschwindigkeit, seinen Flug im Wirbelfeld beginnt, sei es, daß es durch Zusammenstöße mit Restgasmolekülen aus seiner richtigen Flugbahn abgelenkt wird. Außerdem gleicht aber das Feld auch noch seine eigenen Fehler aus, z. B. sind geringe Abweichungen von der Rotationssymmetrie der Anordnung, die ja niemals in idealer Weise erfüllt sein kann, bei der vorliegenden Anordnung ohne schädliche Wirkung.

Die Führung der Elektronen auf Kreisbahnen mit Hilfe eines magnetischen Führungsfeldes, die durch die Bemessung der Felder nach der Erfindung in vorteilhafter Weise gelingt, hat den prinzipiellen Vorteil, daß man zur Führung eines Elektrons, beispielsweise von 11 Millionen Volt Geschwindigkeit, nur ein Magnetfeld von etwa 7000 Gauß braucht, während bei der Führung des Elektrons durch ein radiales elektrisches Feld ein solches von mehreren Millionen Volt notwendig wäre.

Der grundsätzliche Aufbau der Anordnung ist aus Fig. 1 ersichtlich. Die Anordnung muß im Prinzip etwa folgendermaßen aussehen:

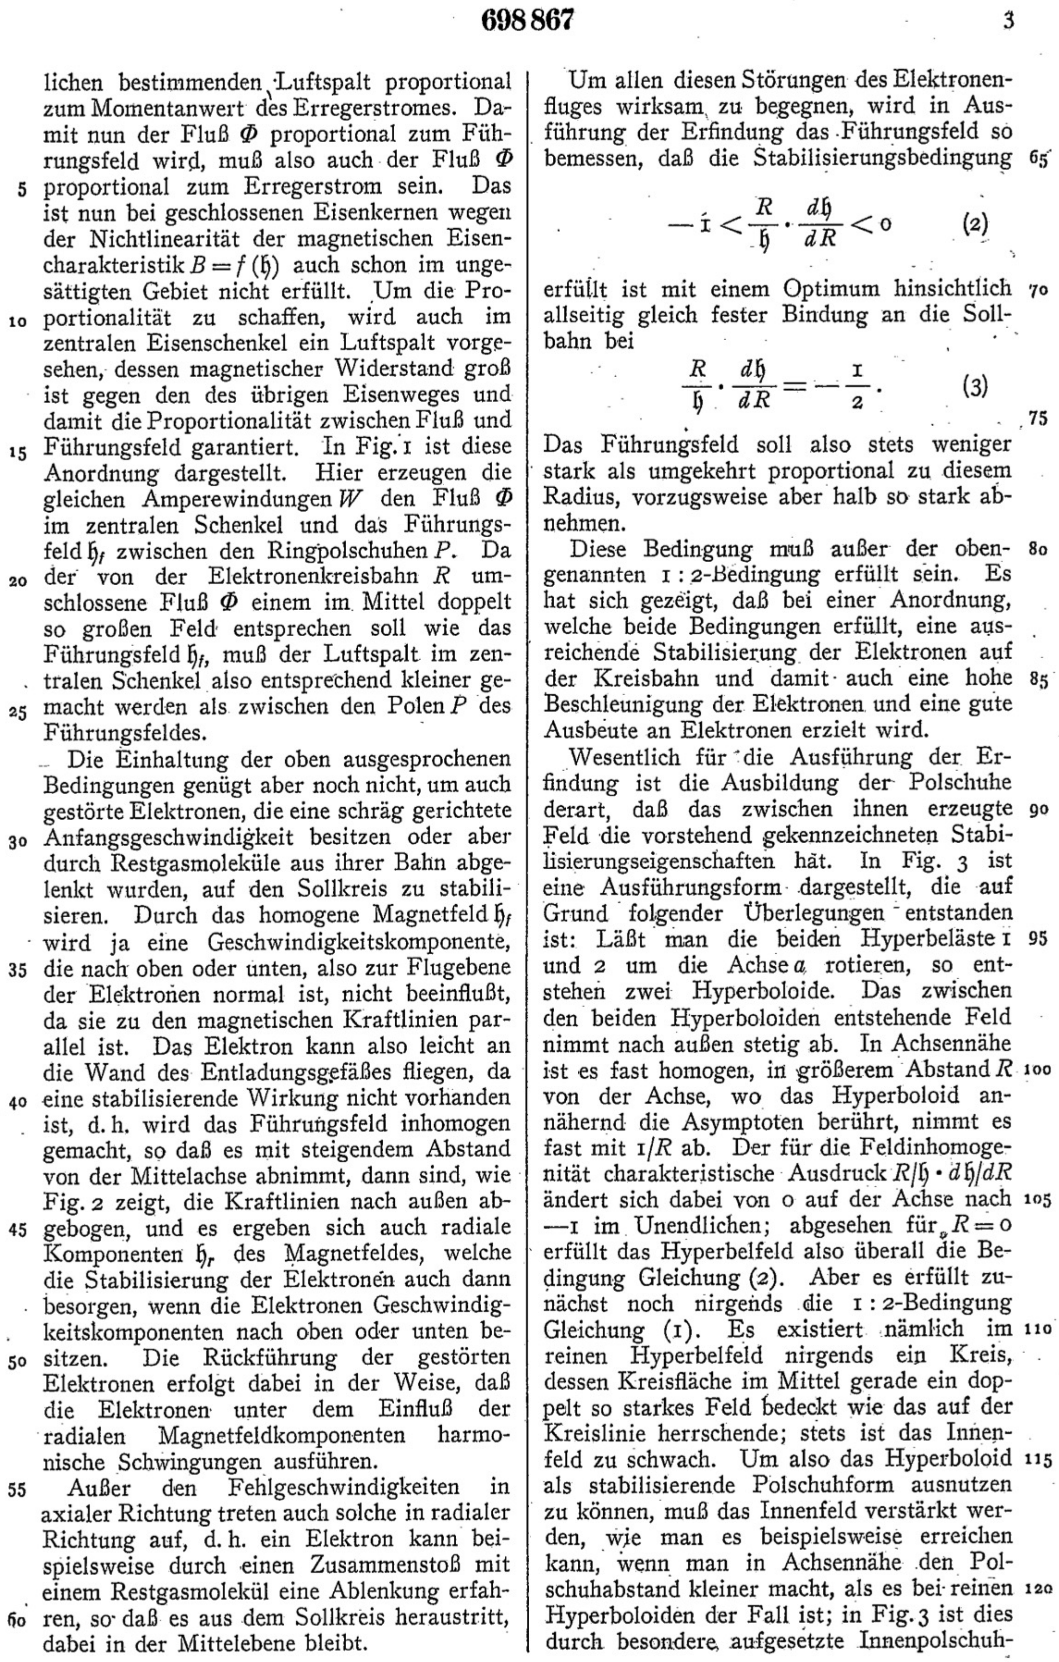
Ein zentraler Eisenschenkel führt den sich zeitlich ändernden Magnetfluß Φ und erzeugt um sich das elektrische Wirbelfeld. Das Führungsfeld $\mathfrak{h}_f$ wird von zwei ringförmigen Polschuhen erzeugt, die den zentralen Eisenschenkel und damit den zentralen Magnetfluß leiten. Das Führungsfeld darf nicht, wie vorgeschlagen ist, von einem Dauermagneten erzeugt werden; denn wenn mit der Zeit die kreisenden Elektronen rascher werden, würde bei gleichbleibender Stärke des Führungsfeldes der Bahnradius immer größer werden. Um den Bahnradius konstant zu lassen, muß das Führungsfeld $\mathfrak{h}_f$ also mit der Zeit ansteigen. Da die Elektronengeschwindigkeit nur vom zentralen Magnetfluß abhängt und da die Beziehung zwischen Elektronengeschwindigkeit und Führungsfeld für konstant bleibenden Bahnradius R ebenfalls eindeutig ist, muß die notwendige Führungsfeldstärke $\mathfrak{h}_f$ allein durch die Größe des zentralen Flusses gegeben sein. Man findet als Bedingung dafür, daß der Bahnradius R unverändert bleibt:

$$\varnothing = 2\, R^2 \pi\, \mathfrak{h}_f = 2\, R^2 \pi\, B_f \text{ im Vakuum.} \quad (1)$$

Der Fluß Φ muß also gerade doppelt so groß sein, wie er es wäre, wenn das Führungsfeld $\mathfrak{h}_f$ homogen das ganz Innere der Kreisbahn ausfüllt, damit der Radius R der Elektronenbahnen unverändert bleibt (1 : 2-Bedingung). Diese Bedingung gilt auch noch dann exakt, wenn man in das Gebiet relativistischer Geschwindigkeiten kommt; sie gilt auch dem Vorzeichen nach, d. h. zentraler Fluß und Führungsfeld müssen gleichgerichtet im Verhältnis 1 : 2 ansteigen. Nimmt man die Richtung des zentralen Flusses Φ als positiv an, so gibt eine Vergrößerung des Flusses ein Wirbelfeld mit eindeutig festliegendem Umlaufsinn. Das Führungsfeld muß dann so gerichtet sein, daß in ihm die Elektronen mit solchem Umlaufsinn kreisen, daß sie vom Wirbelfeld beschleunigt werden; ein entgegengesetzt gerichtetes Führungsfeld würde dagegen die Elektronen gegen das Wirbelfeld kreisen lassen, so daß die Elektronen gebremst würden.

Die Erkenntnis, daß zentraler Fluß Φ und Führungsfeld $\mathfrak{h}_f$ gleichgerichtet und einander proportional sein müssen, führt dazu, sie beide durch die gleiche Wicklung zu erregen. Dann ist das Führungsfeld $\mathfrak{h}_f$ mit seinem den magnetischen Widerstand im wesent-

Figure C.15: Max Steenbeck's first patent on betatrons (DE 698,867), filed in 1935.



lichen bestimmenden Luftspalt proportional zum Momentanwert des Erregerstromes. Damit nun der Fluß Φ proportional zum Führungsfeld wird, muß also auch der Fluß Φ proportional zum Erregerstrom sein. Das ist nun bei geschlossenen Eisenkernen wegen der Nichtlinearität der magnetischen Eisencharakteristik $B = f(\mathfrak{h})$ auch schon im ungesättigten Gebiet nicht erfüllt. Um die Proportionalität zu schaffen, wird auch im zentralen Eisenschenkel ein Luftspalt vorgesehen, dessen magnetischer Widerstand groß ist gegen den des übrigen Eisenweges und damit die Proportionalität zwischen Fluß und Führungsfeld garantiert. In Fig. 1 ist diese Anordnung dargestellt. Hier erzeugen die gleichen Amperewindungen W den Fluß Φ im zentralen Schenkel und das Führungsfeld $\mathfrak{h}_f$ zwischen den Ringpolschuhen P. Da der von der Elektronenkreisbahn R umschlossene Fluß Φ einem im Mittel doppelt so großen Feld entsprechen soll wie das Führungsfeld $\mathfrak{h}_f$, muß der Luftspalt im zentralen Schenkel also entsprechend kleiner gemacht werden als zwischen den Polen P des Führungsfeldes.

Die Einhaltung der oben ausgesprochenen Bedingungen genügt aber noch nicht, um auch gestörte Elektronen, die eine schräg gerichtete Anfangsgeschwindigkeit besitzen oder aber durch Restgasmoleküle aus ihrer Bahn abgelenkt wurden, auf den Sollkreis zu stabilisieren. Durch das homogene Magnetfeld $\mathfrak{h}_f$ wird ja eine Geschwindigkeitskomponente, die nach oben oder unten, also zur Flugebene der Elektronen normal ist, nicht beeinflußt, da sie zu den magnetischen Kraftlinien parallel ist. Das Elektron kann also leicht an die Wand des Entladungsgefäßes fliegen, da eine stabilisierende Wirkung nicht vorhanden ist, d. h. wird das Führungsfeld inhomogen gemacht, so daß es mit steigendem Abstand von der Mittelachse abnimmt, dann sind, wie Fig. 2 zeigt, die Kraftlinien nach außen abgebogen, und es ergeben sich auch radiale Komponenten $\mathfrak{h}_r$ des Magnetfeldes, welche die Stabilisierung der Elektronen auch dann besorgen, wenn die Elektronen Geschwindigkeitskomponenten nach oben oder unten besitzen. Die Rückführung der gestörten Elektronen erfolgt dabei in der Weise, daß die Elektronen unter dem Einfluß der radialen Magnetfeldkomponenten harmonische Schwingungen ausführen.

Außer den Fehlgeschwindigkeiten in axialer Richtung treten auch solche in radialer Richtung auf, d. h. ein Elektron kann beispielsweise durch einen Zusammenstoß mit einem Restgasmolekül eine Ablenkung erfahren, so daß es aus dem Sollkreis heraustritt, dabei in der Mittelebene bleibt.

Um allen diesen Störungen des Elektronenfluges wirksam zu begegnen, wird in Ausführung der Erfindung das Führungsfeld so bemessen, daß die Stabilisierungsbedingung

$$-1 < \frac{R}{\mathfrak{h}} \cdot \frac{d\mathfrak{h}}{dR} < 0 \qquad (2)$$

erfüllt ist mit einem Optimum hinsichtlich allseitig gleich fester Bindung an die Sollbahn bei

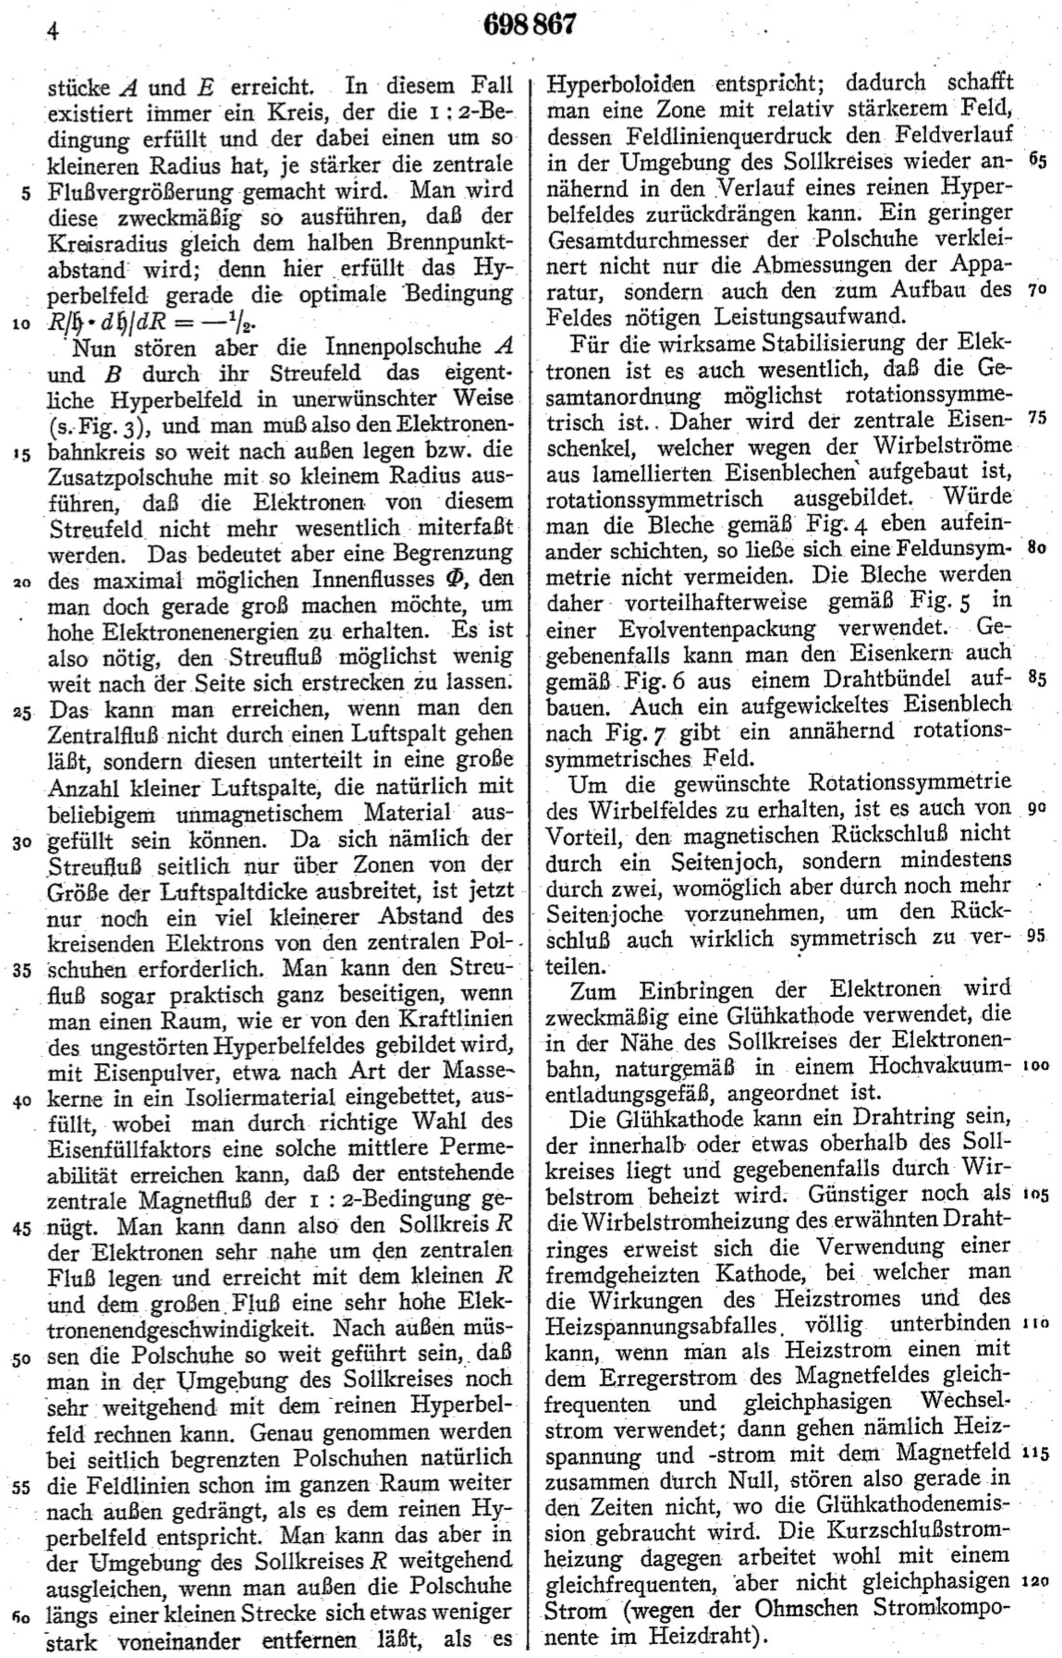
$$\frac{R}{\mathfrak{h}} \cdot \frac{d\mathfrak{h}}{dR} = -\frac{1}{2}. \qquad (3)$$

Das Führungsfeld soll also stets weniger stark als umgekehrt proportional zu diesem Radius, vorzugsweise aber halb so stark abnehmen.

Diese Bedingung muß außer der obengenannten 1 : 2-Bedingung erfüllt sein. Es hat sich gezeigt, daß bei einer Anordnung, welche beide Bedingungen erfüllt, eine ausreichende Stabilisierung der Elektronen auf der Kreisbahn und damit auch eine hohe Beschleunigung der Elektronen und eine gute Ausbeute an Elektronen erzielt wird.

Wesentlich für die Ausführung der Erfindung ist die Ausbildung der Polschuhe derart, daß das zwischen ihnen erzeugte Feld die vorstehend gekennzeichneten Stabilisierungseigenschaften hat. In Fig. 3 ist eine Ausführungsform dargestellt, die auf Grund folgender Überlegungen entstanden ist: Läßt man die beiden Hyperbeläste 1 und 2 um die Achse a rotieren, so entstehen zwei Hyperboloide. Das zwischen den beiden Hyperboloiden entstehende Feld nimmt nach außen stetig ab. In Achsennähe ist es fast homogen, in größerem Abstand R von der Achse, wo das Hyperboloid annähernd die Asymptoten berührt, nimmt es fast mit $1/R$ ab. Der für die Feldinhomogenität charakteristische Ausdruck $R/\mathfrak{h} \cdot d\mathfrak{h}/dR$ ändert sich dabei von 0 auf der Achse nach -1 im Unendlichen; abgesehen für $R = 0$ erfüllt das Hyperbelfeld also überall die Bedingung Gleichung (2). Aber es erfüllt zunächst noch nirgends die 1 : 2-Bedingung Gleichung (1). Es existiert nämlich im reinen Hyperbelfeld nirgends ein Kreis, dessen Kreisfläche im Mittel gerade ein doppelt so starkes Feld bedeckt wie das auf der Kreislinie herrschende; stets ist das Innenfeld zu schwach. Um also das Hyperboloid als stabilisierende Polschuhform ausnutzen zu können, muß das Innenfeld verstärkt werden, wie man es beispielsweise erreichen kann, wenn man in Achsennähe den Polschuhabstand kleiner macht, als es bei reinen Hyperboloiden der Fall ist; in Fig. 3 ist dies durch besondere, aufgesetzte Innenpolschuh-

Figure C.16: Max Steenbeck's first patent on betatrons (DE 698,867), filed in 1935.



stücke *A* und *E* erreicht. In diesem Fall existiert immer ein Kreis, der die 1 : 2-Bedingung erfüllt und der dabei einen um so kleineren Radius hat, je stärker die zentrale Flußvergrößerung gemacht wird. Man wird diese zweckmäßig so ausführen, daß der Kreisradius gleich dem halben Brennpunktabstand wird; denn hier erfüllt das Hyperbelfeld gerade die optimale Bedingung $R/\mathfrak{H} \cdot d\mathfrak{H}/dR = -{}^1/_2$.

Nun stören aber die Innenpolschuhe *A* und *B* durch ihr Streufeld das eigentliche Hyperbelfeld in unerwünschter Weise (s. Fig. 3), und man muß also den Elektronenbahnkreis so weit nach außen legen bzw. die Zusatzpolschuhe mit so kleinem Radius ausführen, daß die Elektronen von diesem Streufeld nicht mehr wesentlich miterfaßt werden. Das bedeutet aber eine Begrenzung des maximal möglichen Innenflusses Φ, den man doch gerade groß machen möchte, um hohe Elektronenenergien zu erhalten. Es ist also nötig, den Streufluß möglichst wenig weit nach der Seite sich erstrecken zu lassen. Das kann man erreichen, wenn man den Zentralfluß nicht durch einen Luftspalt gehen läßt, sondern diesen unterteilt in eine große Anzahl kleiner Luftspalte, die natürlich mit beliebigem unmagnetischem Material ausgefüllt sein können. Da sich nämlich der Streufluß seitlich nur über Zonen von der Größe der Luftspaltdicke ausbreitet, ist jetzt nur noch ein viel kleinerer Abstand des kreisenden Elektrons von den zentralen Polschuhen erforderlich. Man kann den Streufluß sogar praktisch ganz beseitigen, wenn man einen Raum, wie er von den Kraftlinien des ungestörten Hyperbelfeldes gebildet wird, mit Eisenpulver, etwa nach Art der Massekerne in ein Isoliermaterial eingebettet, ausfüllt, wobei man durch richtige Wahl des Eisenfüllfaktors eine solche mittlere Permeabilität erreichen kann, daß der entstehende zentrale Magnetfluß der 1 : 2-Bedingung genügt. Man kann dann also den Sollkreis *R* der Elektronen sehr nahe um den zentralen Fluß legen und erreicht mit dem kleinen *R* und dem großen Fluß eine sehr hohe Elektronenendgeschwindigkeit. Nach außen müssen die Polschuhe so weit geführt sein, daß man in der Umgebung des Sollkreises noch sehr weitgehend mit dem reinen Hyperbelfeld rechnen kann. Genau genommen werden bei seitlich begrenzten Polschuhen natürlich die Feldlinien schon im ganzen Raum weiter nach außen gedrängt, als es dem reinen Hyperbelfeld entspricht. Man kann das aber in der Umgebung des Sollkreises *R* weitgehend ausgleichen, wenn man außen die Polschuhe längs einer kleinen Strecke sich etwas weniger stark voneinander entfernen läßt, als es Hyperboloiden entspricht; dadurch schafft man eine Zone mit relativ stärkerem Feld, dessen Feldlinienquerdruck den Feldverlauf in der Umgebung des Sollkreises wieder annähernd in den Verlauf eines reinen Hyperbelfeldes zurückdrängen kann. Ein geringer Gesamtdurchmesser der Polschuhe verkleinert nicht nur die Abmessungen der Apparatur, sondern auch den zum Aufbau des Feldes nötigen Leistungsaufwand.

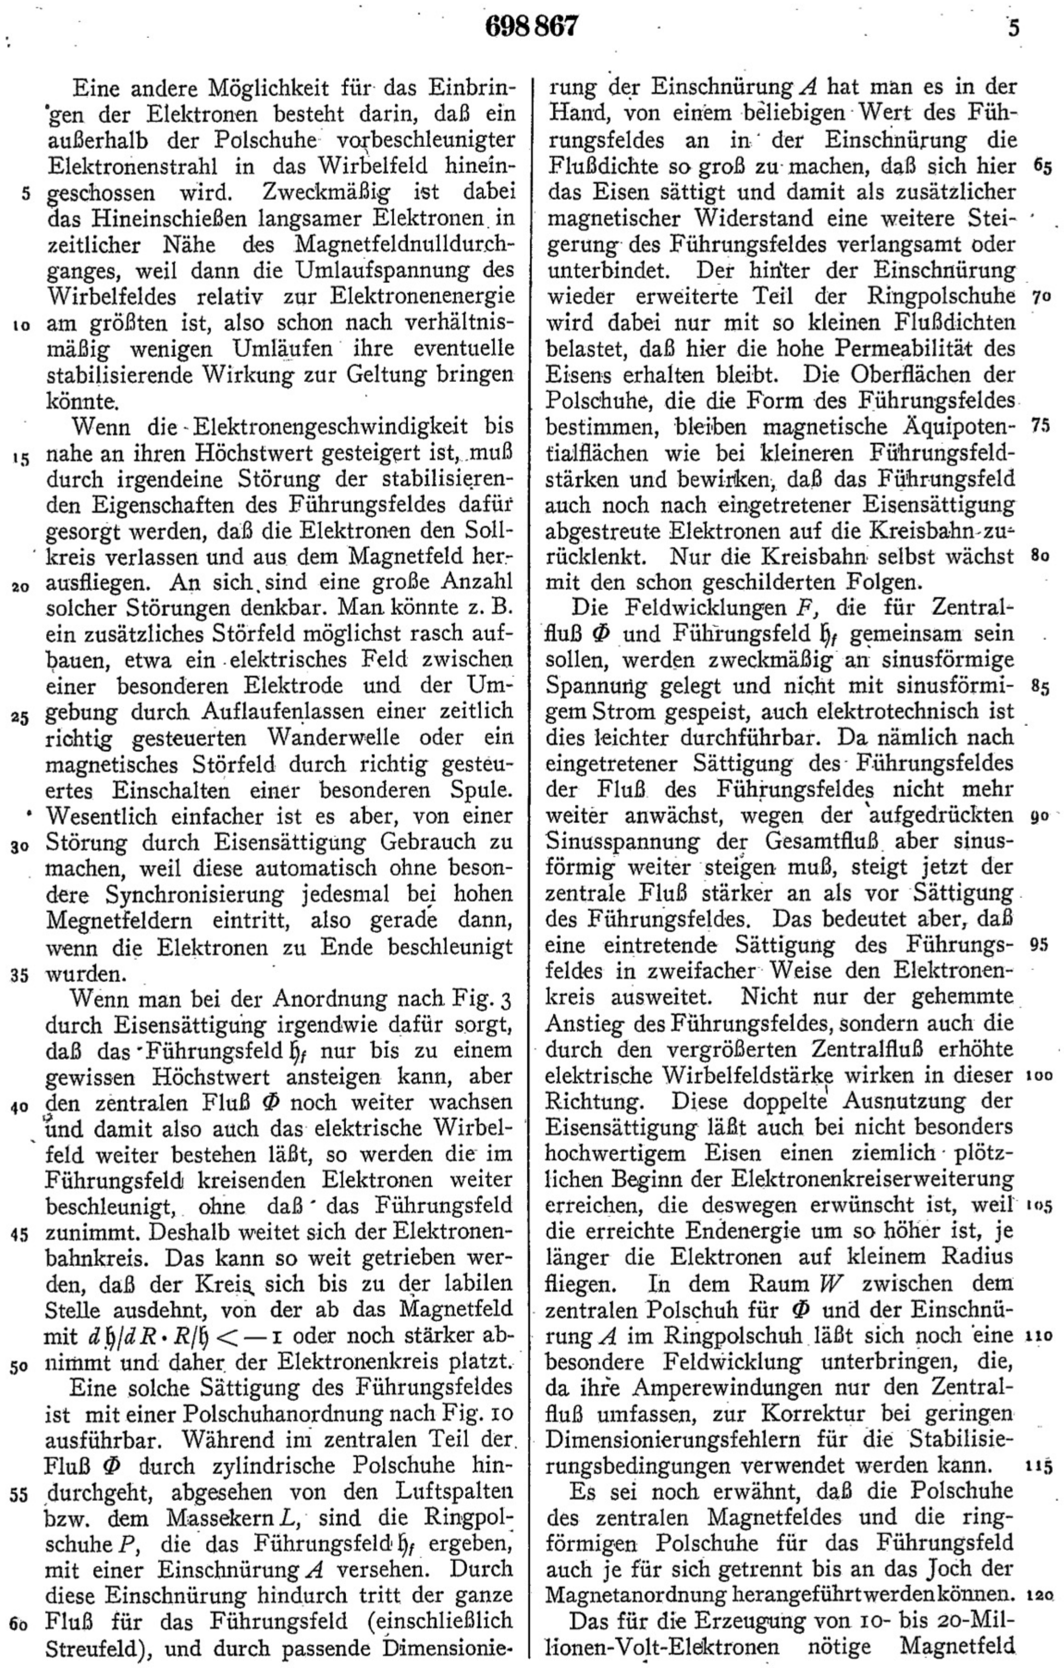
Für die wirksame Stabilisierung der Elektronen ist es auch wesentlich, daß die Gesamtanordnung möglichst rotationssymmetrisch ist. Daher wird der zentrale Eisenschenkel, welcher wegen der Wirbelströme aus lamellierten Eisenblechen aufgebaut ist, rotationssymmetrisch ausgebildet. Würde man die Bleche gemäß Fig. 4 eben aufeinander schichten, so ließe sich eine Feldunsymmetrie nicht vermeiden. Die Bleche werden daher vorteilhafterweise gemäß Fig. 5 in einer Evolventenpackung verwendet. Gegebenenfalls kann man den Eisenkern auch gemäß Fig. 6 aus einem Drahtbündel aufbauen. Auch ein aufgewickeltes Eisenblech nach Fig. 7 gibt ein annähernd rotationssymmetrisches Feld.

Um die gewünschte Rotationssymmetrie des Wirbelfeldes zu erhalten, ist es auch von Vorteil, den magnetischen Rückschluß nicht durch ein Seitenjoch, sondern mindestens durch zwei, womöglich aber durch noch mehr Seitenjoche vorzunehmen, um den Rückschluß auch wirklich symmetrisch zu verteilen.

Zum Einbringen der Elektronen wird zweckmäßig eine Glühkathode verwendet, die in der Nähe des Sollkreises der Elektronenbahn, naturgemäß in einem Hochvakuumentladungsgefäß, angeordnet ist.

Die Glühkathode kann ein Drahtring sein, der innerhalb oder etwas oberhalb des Sollkreises liegt und gegebenenfalls durch Wirbelstrom beheizt wird. Günstiger noch als die Wirbelstromheizung des erwähnten Drahtringes erweist sich die Verwendung einer fremdgeheizten Kathode, bei welcher man die Wirkungen des Heizstromes und des Heizspannungsabfalles völlig unterbinden kann, wenn man als Heizstrom einen mit dem Erregerstrom des Magnetfeldes gleichfrequenten und gleichphasigen Wechselstrom verwendet; dann gehen nämlich Heizspannung und -strom mit dem Magnetfeld zusammen durch Null, stören also gerade in den Zeiten nicht, wo die Glühkathodenemission gebraucht wird. Die Kurzschlußstromheizung dagegen arbeitet wohl mit einem gleichfrequenten, aber nicht gleichphasigen Strom (wegen der Ohmschen Stromkomponente im Heizdraht).

Figure C.17: Max Steenbeck's first patent on betatrons (DE 698,867), filed in 1935.



698 867 5

Eine andere Möglichkeit für das Einbringen der Elektronen besteht darin, daß ein außerhalb der Polschuhe vorbeschleunigter Elektronenstrahl in das Wirbelfeld hineingeschossen wird. Zweckmäßig ist dabei das Hineinschießen langsamer Elektronen in zeitlicher Nähe des Magnetfeldnulldurchganges, weil dann die Umlaufspannung des Wirbelfeldes relativ zur Elektronenenergie am größten ist, also schon nach verhältnismäßig wenigen Umläufen ihre eventuelle stabilisierende Wirkung zur Geltung bringen könnte.

Wenn die Elektronengeschwindigkeit bis nahe an ihren Höchstwert gesteigert ist, muß durch irgendeine Störung der stabilisierenden Eigenschaften des Führungsfeldes dafür gesorgt werden, daß die Elektronen den Sollkreis verlassen und aus dem Magnetfeld herausfliegen. An sich sind eine große Anzahl solcher Störungen denkbar. Man könnte z. B. ein zusätzliches Störfeld möglichst rasch aufbauen, etwa ein elektrisches Feld zwischen einer besonderen Elektrode und der Umgebung durch Auflaufenlassen einer zeitlich richtig gesteuerten Wanderwelle oder ein magnetisches Störfeld durch richtig gesteuertes Einschalten einer besonderen Spule. Wesentlich einfacher ist es aber, von einer Störung durch Eisensättigung Gebrauch zu machen, weil diese automatisch ohne besondere Synchronisierung jedesmal bei hohen Megnetfeldern eintritt, also gerade dann, wenn die Elektronen zu Ende beschleunigt wurden.

Wenn man bei der Anordnung nach Fig. 3 durch Eisensättigung irgendwie dafür sorgt, daß das Führungsfeld $\mathfrak{h}_f$ nur bis zu einem gewissen Höchstwert ansteigen kann, aber den zentralen Fluß Φ noch weiter wachsen und damit also auch das elektrische Wirbelfeld weiter bestehen läßt, so werden die im Führungsfeld kreisenden Elektronen weiter beschleunigt, ohne daß das Führungsfeld zunimmt. Deshalb weitet sich der Elektronenbahnkreis. Das kann so weit getrieben werden, daß der Kreis sich bis zu der labilen Stelle ausdehnt, von der ab das Magnetfeld mit $d\mathfrak{h}/dR \cdot R/\mathfrak{h} < -1$ oder noch stärker abnimmt und daher der Elektronenkreis platzt.

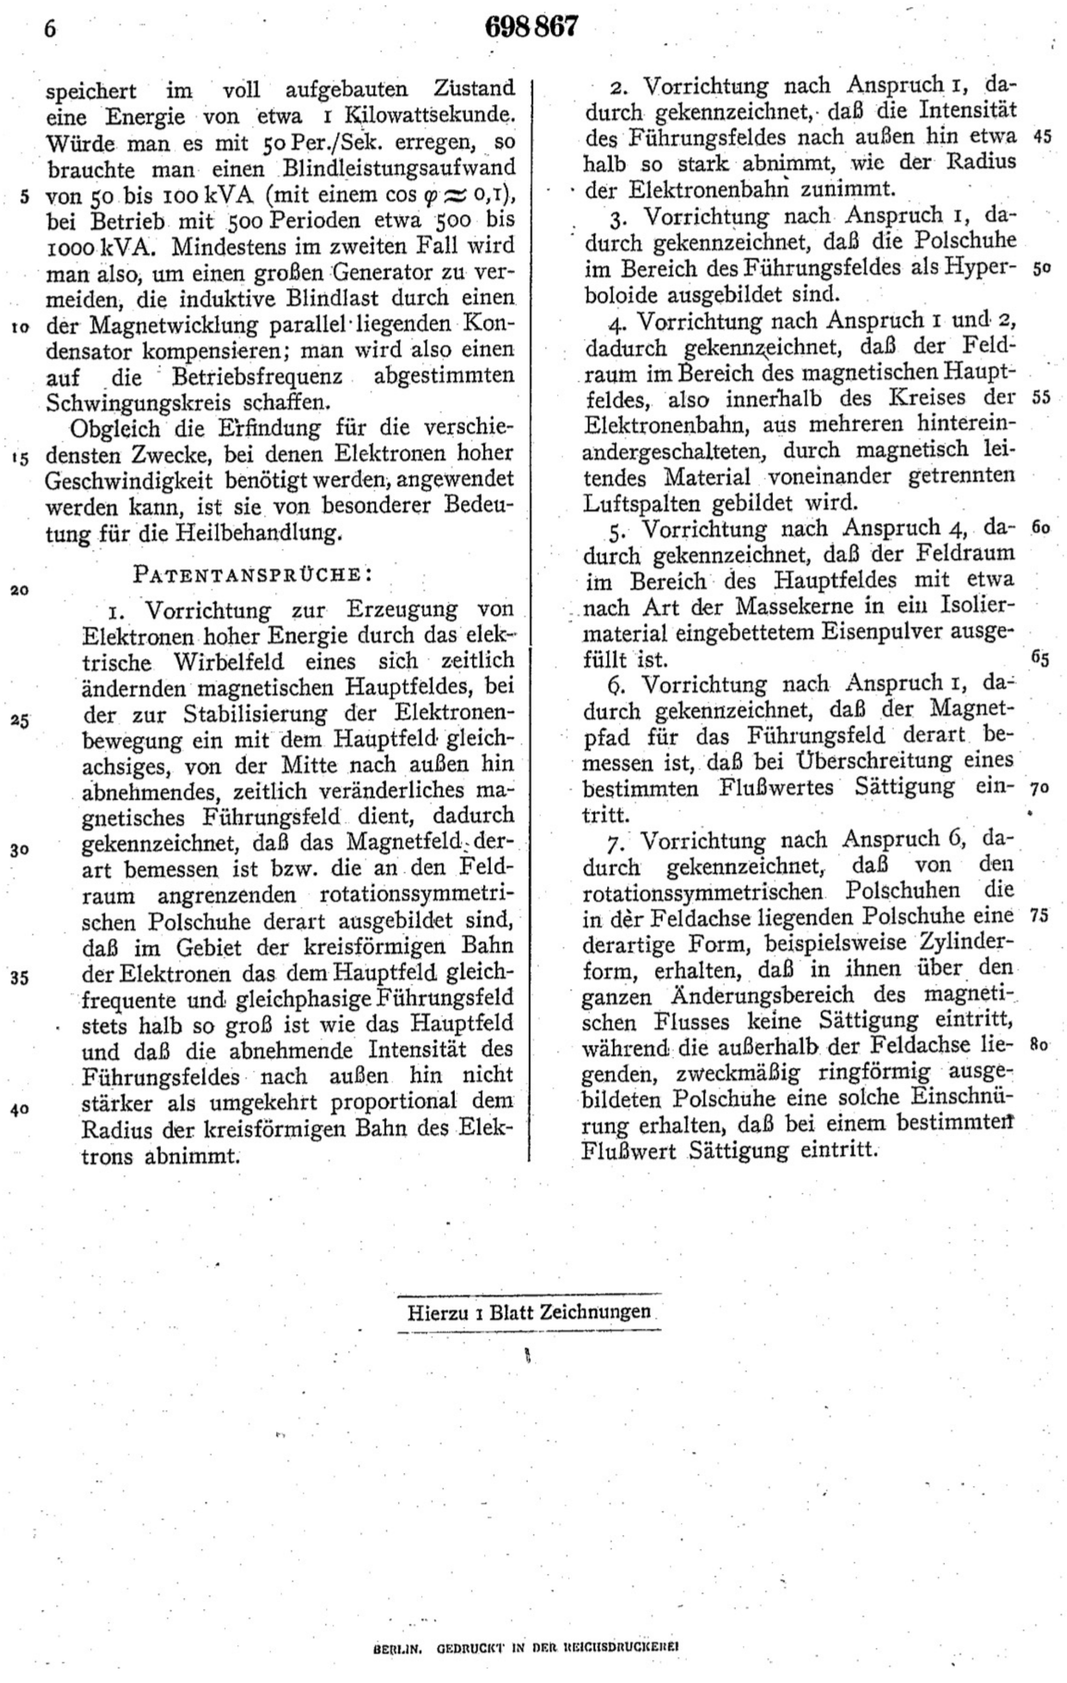
Eine solche Sättigung des Führungsfeldes ist mit einer Polschuhanordnung nach Fig. 10 ausführbar. Während im zentralen Teil der Fluß Φ durch zylindrische Polschuhe hindurchgeht, abgesehen von den Luftspalten bzw. dem Massekern L, sind die Ringpolschuhe P, die das Führungsfeld $\mathfrak{h}_f$ ergeben, mit einer Einschnürung A versehen. Durch diese Einschnürung hindurch tritt der ganze Fluß für das Führungsfeld (einschließlich Streufeld), und durch passende Dimensionierung der Einschnürung A hat man es in der Hand, von einem beliebigen Wert des Führungsfeldes an in der Einschnürung die Flußdichte so groß zu machen, daß sich hier das Eisen sättigt und damit als zusätzlicher magnetischer Widerstand eine weitere Steigerung des Führungsfeldes verlangsamt oder unterbindet. Der hinter der Einschnürung wieder erweiterte Teil der Ringpolschuhe wird dabei nur mit so kleinen Flußdichten belastet, daß hier die hohe Permeabilität des Eisens erhalten bleibt. Die Oberflächen der Polschuhe, die die Form des Führungsfeldes bestimmen, bleiben magnetische Äquipotentialflächen wie bei kleineren Führungsfeldstärken und bewirken, daß das Führungsfeld auch noch nach eingetretener Eisensättigung abgestreute Elektronen auf die Kreisbahn zurücklenkt. Nur die Kreisbahn selbst wächst mit den schon geschilderten Folgen.

Die Feldwicklungen F, die für Zentralfluß Φ und Führungsfeld $\mathfrak{h}_f$ gemeinsam sein sollen, werden zweckmäßig an sinusförmige Spannung gelegt und nicht mit sinusförmigem Strom gespeist, auch elektrotechnisch ist dies leichter durchführbar. Da nämlich nach eingetretener Sättigung des Führungsfeldes der Fluß des Führungsfeldes nicht mehr weiter anwächst, wegen der aufgedrückten Sinusspannung der Gesamtfluß aber sinusförmig weiter steigen muß, steigt jetzt der zentrale Fluß stärker an als vor Sättigung des Führungsfeldes. Das bedeutet aber, daß eine eintretende Sättigung des Führungsfeldes in zweifacher Weise den Elektronenkreis ausweitet. Nicht nur der gehemmte Anstieg des Führungsfeldes, sondern auch die durch den vergrößerten Zentralfluß erhöhte elektrische Wirbelfeldstärke wirken in dieser Richtung. Diese doppelte Ausnutzung der Eisensättigung läßt auch bei nicht besonders hochwertigem Eisen einen ziemlich plötzlichen Beginn der Elektronenkreiserweiterung erreichen, die deswegen erwünscht ist, weil die erreichte Endenergie um so höher ist, je länger die Elektronen auf kleinem Radius fliegen. In dem Raum W zwischen dem zentralen Polschuh für Φ und der Einschnürung A im Ringpolschuh läßt sich noch eine besondere Feldwicklung unterbringen, die, da ihre Amperewindungen nur den Zentralfluß umfassen, zur Korrektur bei geringen Dimensionierungsfehlern für die Stabilisierungsbedingungen verwendet werden kann.

Es sei noch erwähnt, daß die Polschuhe des zentralen Magnetfeldes und die ringförmigen Polschuhe für das Führungsfeld auch je für sich getrennt bis an das Joch der Magnetanordnung herangeführt werden können.

Das für die Erzeugung von 10- bis 20-Millionen-Volt-Elektronen nötige Magnetfeld

Figure C.18: Max Steenbeck's first patent on betatrons (DE 698,867), filed in 1935.



speichert im voll aufgebauten Zustand eine Energie von etwa 1 Kilowattsekunde. Würde man es mit 50 Per./Sek. erregen, so brauchte man einen Blindleistungsaufwand von 50 bis 100 kVA (mit einem $\cos\varphi \approx 0{,}1$), bei Betrieb mit 500 Perioden etwa 500 bis 1000 kVA. Mindestens im zweiten Fall wird man also, um einen großen Generator zu vermeiden, die induktive Blindlast durch einen der Magnetwicklung parallel liegenden Kondensator kompensieren; man wird also einen auf die Betriebsfrequenz abgestimmten Schwingungskreis schaffen.

Obgleich die Erfindung für die verschiedensten Zwecke, bei denen Elektronen hoher Geschwindigkeit benötigt werden, angewendet werden kann, ist sie von besonderer Bedeutung für die Heilbehandlung.

PATENTANSPRÜCHE:

1. Vorrichtung zur Erzeugung von Elektronen hoher Energie durch das elektrische Wirbelfeld eines sich zeitlich ändernden magnetischen Hauptfeldes, bei der zur Stabilisierung der Elektronenbewegung ein mit dem Hauptfeld gleichachsiges, von der Mitte nach außen hin abnehmendes, zeitlich veränderliches magnetisches Führungsfeld dient, dadurch gekennzeichnet, daß das Magnetfeld derart bemessen ist bzw. die an den Feldraum angrenzenden rotationssymmetrischen Polschuhe derart ausgebildet sind, daß im Gebiet der kreisförmigen Bahn der Elektronen das dem Hauptfeld gleichfrequente und gleichphasige Führungsfeld stets halb so groß ist wie das Hauptfeld und daß die abnehmende Intensität des Führungsfeldes nach außen hin nicht stärker als umgekehrt proportional dem Radius der kreisförmigen Bahn des Elektrons abnimmt.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß die Intensität des Führungsfeldes nach außen hin etwa halb so stark abnimmt, wie der Radius der Elektronenbahn zunimmt.

3. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß die Polschuhe im Bereich des Führungsfeldes als Hyperboloide ausgebildet sind.

4. Vorrichtung nach Anspruch 1 und 2, dadurch gekennzeichnet, daß der Feldraum im Bereich des magnetischen Hauptfeldes, also innerhalb des Kreises der Elektronenbahn, aus mehreren hintereinandergeschalteten, durch magnetisch leitendes Material voneinander getrennten Luftspalten gebildet wird.

5. Vorrichtung nach Anspruch 4, dadurch gekennzeichnet, daß der Feldraum im Bereich des Hauptfeldes mit etwa nach Art der Massekerne in ein Isoliermaterial eingebettetem Eisenpulver ausgefüllt ist.

6. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß der Magnetpfad für das Führungsfeld derart bemessen ist, daß bei Überschreitung eines bestimmten Flußwertes Sättigung eintritt.

7. Vorrichtung nach Anspruch 6, dadurch gekennzeichnet, daß von den rotationssymmetrischen Polschuhen die in der Feldachse liegenden Polschuhe eine derartige Form, beispielsweise Zylinderform, erhalten, daß in ihnen über den ganzen Änderungsbereich des magnetischen Flusses keine Sättigung eintritt, während die außerhalb der Feldachse liegenden, zweckmäßig ringförmig ausgebildeten Polschuhe eine solche Einschnürung erhalten, daß bei einem bestimmten Flußwert Sättigung eintritt.

THE SUPER-CYCLOTRON IN BISINGEN.

The Super-cyclotron has been invented and designed by a man called Daellenbach, a Swiss citizen who has been living in Germany for many years and is a convinced nazi.

Daellenbach is a very able engineer; he developed the Pintsch rectifier when he was chief of the electrical laboratories of Julius Pintsch and Co. in Fuerstenwalde; then did a lot of work on resonator (Schwingtopf) theory in connection with ultra-short wave generators of the Klystron (Clystron?) type. It is in connection with this work on resonators that he got the idea of the supercyclotron.

Daellenbach was already working in Bisingen (Forschungsstelle E) for the German government. He submitted his plans for the supercyclotron to the Kaiser Wilhelm Gesellschaft, which is a foundation for the encouragement of science, which finances the Kaiser Wilhelm Institutes for the different sciences. When a new research project is submitted to the Kaiser Wilhelm Gesellschaft, the sponsor of the project must hold a "Colloquium" (a controversial report) in front of a public consisting of scientists of the K.W. institutes and of members of the Gesellschaft, mainly big industrialists who put up the money.

Daellenbach had his Colloquium at a sitting of the K.W. Gesellschaft last July (1944); many of the scientists were against the project, mainly because of the very untried elements; but Daellenbach had the complete design ready and detailed, and was extremely well prepared to meet all objections made by his contradictors; the meeting was very favourably impressed by the thoroughness of his preparation (and probably by his past record) and decided to grant a credit up to 100 million marks for the immediate construction of a super-cyclotron for 100 to 200 million volt. Ordinarily this would take about four years, but the construction is being rushed as a war measure and it is likely that the supercyclotron will be ready in about a year from the start of manufacture, that is, in the summer of 1945. It must be noted that the design was quite ready at the time of the K.W. Gesellschaft sitting last July, so that manufacture could be started at once. A committee consisting of Laue, Heisenberg and Molière meets Daellenbach every week to examine progress; the project enjoys full priority. It seems likely that most of the K.W. Institutes which were formerly in Berlin have now moved to Bisingen.

- 2 -

A very schematic description of the principle on which the supercyclotron works has been obtained by Flute from one of the K.W. Gesellschaft members (a German industrialist) who was present at the Colloquium. Although Daellenbach often comes to Switzerland (he has a visa granting him unlimited journeys from Germany; which shows that the Germans hold him in high esteem) and even sees Flute, he does not give any details about the supercyclotron; he only says he is engaged in work of supreme importance for Germany, ultra secret; also he is very proud of the fact that he meets Laue, Heisenberg and Molière every week (apparently on Wedmnesday afternoon).

The schematic principle of the supercyclotron is as follows:

The main vacuum chamber (1, in fig. I) is a cylindrical rotation body, having an H section, the axis of the cylinder being z, z. This vacuum chamber, which is of enourmous size (about 5 metres outside diametre and 5 metres height) constitutes a colossal resonator; the walls are of very thick copper, water cooled from the outside. When the resonator is excited by means of an aerial insidem it, working at an appropriate resonance frequency, the whole resonator begins to oscillate, and a very high electric field takes place between the two opposite faces (2, 3) which form the bar of the H in the sectional figure; this alternating field gives between 1 million and 3 million volts between the said faces. Inside the vacuum chamber, a very high vacuum must be obtained (at least 10^{-6} mm Hg, and even less) and this present one of the main difficulties in view of the size of the chamber.

Just above face 2 and just below face 3 of the vacuum chamber there is a very strong magnetic field, the direction of the lines of force being perpendicular to the plane of fig. I; the part indicated with 4 and 5 in fig. I lies in the interpolar space of the twin magnet, the actual poles being therefore in front and behind of the plane of fig. 1. If we call y the direction of the horizontal co-ordinate in the plane of fig. I, the magnetic lines of force are parallel to the x direction and the field is concentrated in 4 and 5, just above face 2 and below face 3. In the plane of fig. I (plane y, z) a series of holes or canals are excavated in the material which constitutes the faces 2 and 3 of the vacuum chamber, and in the interpolar pieces 4 and 5; these canals comunicate with the vacuum chamber and inside them reigns the same high vacumm; they are concentric and the centre of each of the two sets of semicircular canals lies in 6 for the upper set and 7 for the lower set. We shall indicate these canals with a, a'; b, b'; .....

m, m'; n, n', for the upper set (with centre in point 6); and with the corresponding capital letters for the lower set, with centre in point 7. Right opposite point a, but in the lower face, abuts in point 8 the canal leading from the source of ions into the vacuum chamber.

If we imagine that a positive particle enters the vacuum chamber in 8 at the moment when face 3 is positive and face 2 is negative, ~~x~~it will be attracted towards face 2 by the electric field (1 to 3 million volt) and will enter canal a, a' in a; the magnetic field will ensure that the particle follows exactly a path corresponding the axis of canal a, a'. By the time the particle reaches again the main chamber in a', the electric field will be inverted, ~~y~~upper face 2 will be positive. lower face 3 negative, so the particle will be further accelerated with 1 to 3 million volt on to face 3, and will enter canal A, A' in A; it will come out in A', be further accelerated across to 2, enter b, b', and so on, ~~the~~ entrance of one set of canals being exactly opposite the exit of the preceding one (A opposite a', b opposite A', B opposite b' and so on). The particle follows therefore a path (indicated in red, dotted line in photograph, in fig. I) which might be called a "race-track spiral"; in that the two halves, upper and lower, of a spiral, are connected with parallel straights, just as a race track consists of two semicircles connected by two straights.

There are about 100 canals, so that the total accelerative potential should correspond to 100 to 200 million volts. At the end, the last canal is n, n'; opposite n' is a further canal with entrance in N, which leads the particle on to the object to be bombarded.

Owing to the fact that, for velocities corresponding to a potential of more than 20 million volts, the apparent mass-increase of the particle due to velocity begins to make itself felt, the magnetic field must be adjusted so as to give the right curvature to the path; this correction requires that the magnetic field should be progressivley stronger in the outer canals: this is obtained by making the pole-pieces in stepped form, the distance between the pole pieces being smaller in correspondence with the outer canals (l, l'; m, m'; n, n') and greater for the inner canals (a, a'; b, b', etc).

The shape of the pole pieces is shown in fig. II, which is a partial section of fig. I along the line Y, Y, at a height corresponding to the height of the centre of the upper set of canals, (centre 6); X, X represents the axis of the upper magnet and the direction of the lines of force; the canals of the upper set appear as small circels (a, a'; ..... n, n') the pole

pieces, 9 and ~~11~~ 10, are stepped and get nearer the farther one gets from axis X, X; the pole pieces are, of course, semi-circular.

The actual constructional details of the supercyclotron are not known; for instance, the exact shape of the magnets, the location of the ions source, etc. Apparently, in order to avoid vacuum discharges across the vacuum chamber, Zircon electrodes are to be used.

As already stated, at the July sitting of the K.W. Gesellschaft, Daellenbach was in a position to counter successfully all objections of the members; a scientific committee, composed of Bothe, Heisenberg and Gentner, had particularly studied the project, and these three raised a lot of objections, but Daellenbach had an answer to everything.

According to Flute, taking into account Daellenbach's experience, the formidable means at his disposal and the advice of his scientific committee, it is probable that the supercyclotron will work successfully.

Subject: Report on German Super-Cyclotron.

To: Major Peer de Silva, P. O. Box 1539, Santa Fe, New Mexico.

1. Attached herewith is the copy of a report dated 16 November 1944 on a German super-cyclotron supposed to have been devised by Dällenbach. The undertaking as described sounds like a large and complicated one involving essential materials and technical personnel. If such a cyclotron were constructed and found to be operable, its main use would probably be as a research tool. It is not clear how this could have any direct or immediate consequence for the German war effort. However, the report claims that the construction is being rushed as a war measure.

2. In order to obtain an opinion as to whether a cyclotron of this kind would be feasible from a technical standpoint, it is suggested that you refer the report to Dr. Luis W. Alvarez. It may also be of interest to Dr. J. R. Oppenheimer and to Dr. Philip Morrison.

3. Could you return this memorandum with any comments you think pertinent?

INTER-OFFICE MEMORANDUM

DATE 26 January 1945

TO: Major Peer de Silva

FROM: L. W. Alvarez

SUBJECT: German Super-Cyclotron

I have just finished reading the very interesting report on the super-cyclotron designed by Mr. Dallenbach. My reaction to it is that the Germans are certainly wasting a lot of time and money on a completely inoperable device, which is quite cheering. I have two reasons for believing that the device will not work and a third which would tend to make the machine useless even if the first two reasons did not exist. The real trouble with the machine is that the magnetic field is so arranged as to defocus any positive ions during their acceleration period. It is a well-known fact, both theoretical and experimental, that if a cyclotron is to work, the magnetic lines of force must bulge away from the center or curvature of the ion paths. In fact, this criterion sets an upper limit to the energy which can be obtained in a cyclotron for any particular acceleration voltage between the electrodes. It can easily be seen, and Dallenbach makes this point, that in order to correct for the increase in mass of the positive ions as they acquire high velocities, it is necessary to increase the magnetic field at the outer edges of the cyclotron. However, when one does this, the fundamental laws of electricity and magnetism require that the magnetic lines bulge toward the center of curvature of the ion paths; and as I said before, this tends to push the ions toward the pole pieces of the magnet where they are lost. In all successful cyclotrons it is absolutely necessary that the magnetic field decrease at the edge of the pole pieces to give focussing. This is in the opposite direction to keep the ions in step with the oscillating electric field, so that after a while the ions would get completely out of phase with the electric field and be decelerated. This is the nature of the limit to cyclotron energies. The practical way out of this difficulty is to increase the accelerating voltage on the electrodes so that the total acceleration is done in a relatively few spirals in the magnetic field. If the acceleration is done in a few steps, the loss in phase per revolution cannot add up to a sufficient amount to get the ions into the decelerating condition. If the cyclotron is to be designed as shown in the diagrams, this fact in itself would assure that the device would not operate as advertised. I feel sure that Bothe and Gentner are aware of this difficulty and voiced it at the meeting referred to in the memorandum. Perhaps Mr. Dallenbach's answer to this objection was that he would let the magnetic field fall off towards the edges as is contemplated in the 184" cyclotron at Berkeley.

The second bad feature of the design is that there is no magnetic field across the accelerating gap in the proposed device. This has the same disadvantage mentioned before, ~~now~~ that the magnetic lines of force will bulge towards the center of curvature of the ions, and an extremely strong defocussing action will take place on the first two accelerations. On this point I have some personal experience in that I once proposed a design of electronic accelerator with somewhat similar spacial characteristics, and Mr. R. Oppenheimer calculated the defocussing action for the first two accelerations and found it was enormous. This fact by itself

~~SECRET~~

Maj. Peer de Silva - 2 - 26 January 1945

would render the device completely inoperative. The third point is that the ions are to be accelerated in semicircular tubes. This feature of the design appears to be quite stupid since the tubes can be of no use, and if eliminated, would get around the limitation which I am about to describe. In a cyclotron,ions are accelerated during an appreciable range of phase angle of the electric field; and therefore, ions passing across the accelerating gap receive different energies depending upon the time they cross the gap. Therefore, instead of all following the same paths through the magnetic field, as one indicates in simple discussions of the cyclotron, they are smeared out and occupy all radial positions. If one were to limit their paths to fixed values as Dallenbach does with his tubes, the intensity of theemergent beam would be vanishingly small since only those ions which were accelerated in the very small interval of phase angle would have the proper trojectories. As I say, this is not a fundamental limit to the device, since the tubes and holds in the accelerating electrodes could be turned into a gap as is done in reasonably designed cyclotrons.

To summarize, I should say that with the electrical resonance circuit, which is indicated in the design, it should be perfectly possible to build a one to two hundred million electron volt cyclotron. However, the magnetic field design is completely crazy and would render the machine inoperative. If the Germans really want a high energy cyclotron, Bothe and Gentner are quite capable of designing it for them, ~~but~~ since they understand the criteria, which must be satisfied in order to make the machine work. I think we can take great comfort from the fact that Dallenbach has succeeded in selling someone on the idea that his device will work, since there is no question in my mind that if built according to the plans submitted to me, it will be completely useless.

P. O. Box 1663
Santa Fe, New Mexico

3 February 1945

Subject: Comments on Daellenbach.

To: Major Frank J. Smith, P. O. Box 2610, Washington, D. C.

1. The description of the super-cyclotron forwarded to us from Bern seems to me a perfectly lucid account of a feasible machine. There are details (circular channels for the beam, in homogeneous magnetic field) which sound unlikely to work to me, but they may have been introduced in the indirect transmission of the account. In any case, comparison of this description with the usual unclear and garbled ones we get of purported technical advances, convinces me that this is a genuine account of a large cyclotron built on somewhat novel lines which has been projected for construction by the enemy.

2. The town of Bisingen emerges again as the evacuation laboratory of the KWI, the so-called Forschungsstelle E. The present report is so credible that I am convinced that Bisingen is the place. Recall also the Hechingen references in the Strassbourg material. We have had PW information which contradicts the present source; it seems to me of high importance to establish by photo reconnaissance and other means, whether KWI has really moved to Bisingen.

3. As you say in your covering letter, it is not easy to see any war use for this undertaking; there appears to be no hint that the machine described is really connected with some isotope separation scheme. It may be possible to interpret this enemy activity as an expression of the convictions of top technical and managerial circles that nuclear physics developments can have an important bearing on the war, though they are not quite sure just how this will come about. This seems to be a cheerful sign. I can imagine the Manhattan District building a super-cyclotron, if requested to do so by some of the scientific personnel a couple of years ago, but certainly not in any such sophisticated stage as it has reached now.

INTER-OFFICE MEMORANDUM

DATE February 16, 1945

TO: Major Peer de Silva

FROM: J. R. Oppenheimer

SUBJECT: German Super-Cyclotron

I concur with the technical comments of Dr. Alvarez on the subject of the super-cyclotron, and certainly if the machine were built as described it would encounter the difficulties which he anticipates. I believe, however, that some caution should be exercised in taking the description literally. All three of the evils which he enumerates could be eliminated by relatively trivial design changes, and the origin of the report would not seem to guarantee that these details were accurate.

I should like to make a more general comment. The United States Government has not regarded the development of a super-cyclotron as a war project and has assigned neither materials nor priority to it. There was no doubt about the soundness of the design of Dr. Lawrence's instrument and a good deal of work had already been done on it. Furthermore, this country has from the beginning been in a better position to undertake long range work than would appear likely in Germany. I believe that it should be emphasized that none of us know of any conceivable military development which would result from the construction of such a cyclotron, and it is appropriate to express surprise at its having had the support of the German government at a time of national crisis.

Captured Personnel and Material Branch. 4 September 1944. Special Report 23 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-2 GERMANY: US Wartime Positive Int. (July–Oct. 44)]

Estimate of veracity: Source is considered reliable, talks freely on all matters pertaining to Communication Engineering

Source has been in the German Army since 1928, when he first enlisted and became a Radio Operator. Since that time he was sent to the Technische Hochschule in Berlin on several occasions to study research work for the German Army. He witnessed a very interesting experiment which impressed him very much during the latter part of 1937 and 1938.

The demonstration was performed at the Müggelsee near Berlin and the talk among Army Personnel attending indicated that Neutron Rays were to be employed. A small balloon was released from a boat on the lake which also housed the equipment and the operating personnel. When the rays struck the balloon several hundred feet in the air, it exploded. Source states that when the beam struck the balloon the Hydrogen gas was bombarded causing it to explode.

The beams were then directed upon some old brick buildings. After a short period of waiting for the beam to do its work, it was turned off and the Army spectators were permitted to inspect the brick building. It was discovered that the bricks could be taken and crumbled by a light blow of a hammer. This they were told was brought about by the Neutron ray which was beamed on the building. Very deadly secondary rays are produced by such a beam, they were told, however, it required a tremendous amount of equipment to project such a beam and because of the strong secondary ray which sometimes destroyed the equipment itself, the Army officials decided it would be unwise to employ such equipment for combat.

They were also experimenting with Schumann Rays, which are shorter than Gamma Rays. The idea is to obtain certain gases, such as helium, krypton, and neon, by breaking down atoms. Considerable difficulty is experienced in controlling these rays and on one experiment, source's best friend was killed due to the secondary effect.

Helium is produced by this principle in a factory at Merseburg, near Halle. Facilities are not available to produce it in large quantities. Source never visited this place. He knew of this factory in 1938.

[See document photo on p. 3057.

"Schumann Rays" appears to be a reference to Gerhard Schumann, a particle accelerator physicist known to have developed and tested high-energy accelerators during the war. This report seems to indicate that Schumann, Steenbeck, or other scientists were producing, projecting, and testing intense particle beams as potential weapons by 1937–1938.]

Captured Personnel and Material Br.

Estimate of veracity: Source is considered reliable, talks freely on all matters pertaining to Communication Engineering

Source has been in the German Army since 1928, when he first enlisted and became a Radio Operator. Since that time he was send to the Technische Hochschule in Berlin on several occasions to study research work for the German Army. He witnessed a very interesting experiment which impressed him very much during the latter part of 1937 and 1938.

The demonstration was performed at the Müggelsee near Berlin and the talk among the Army Personnel attending indicated that Neutron Rays were to be employed. A small balloon was released from a boat on the lake which also housed the equipment and the operating personnel. When the rays struck the balloon several hundred feet in the air, it exploded . Source states that when the beam struck the balloon the Hydrogen gas was bombarded causing it to explode.

The beams were then directed upon some old brick buildings. After a short period of waiting for the beam to do its work, it was turned off and the Army spectators were permitted to inspect the brick building. It was discovered that the bricks could be taken and crumbled by a light blow of a hammer. This they were told was brought about by the Neutron ray which was beamed on the building. Very deadly secondary rays are produced by such a beam, they were told, however, it required a tremendous amount of equipment to project such a beam and because of the strong secondary ray which sometimes destroyed the equipment itself, the Army officials decided it would be unwise to employ such equipment for combat.

They were also experimenting with Schumann Rays, which are shorter than Gamma Rays. The idea is to obtain certain gases, such as helium, Krypton, and neon, by breaking down atoms. Considerable difficulty is experienced in controlling these rays and on one experiment, Sources best friend was killed due to the secondary effect.

Helium is produced by this principle in a factory at Merserburg, near Halle. Facilities are not available to produce it in large quantities. Source never visited this place. He knew of this factory in 1938.

Captured Personnel and Material Branch. 1 November 1944. Report 1363. [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-3 GERMANY: US Wartime Positive Int. (Nov. 44–June 45)]

[...] V. DEATH RAY:

A P/W who is a graduate engineer and an inventor with training in chemical metallurgy, gives the following account of a death ray experiment he witnessed at the Berlin Hagenuk ("Hanseatische Apparat Bau Gesellschaft Neufeld & Kuhnke", cf. C.S.D.I.C. (UK) S.I.R. 1029) testing grounds at Tempelhof.

P/W was conducting some experiments there in February 1939. He had just completed experiments of his own when he noticed people assembling on the adjacent testing grounds which belonged to A.E.G. Siemenstadt, Berlin. He inquired regarding the nature of the experiment to take place and was told some form of ray would be displayed. He was permitted to view the experiments by a Dip. Ingenieur, an employee of the A.E.G., who was in charge and with whom P/W was friendly, they having attended the Technische Hochschule at Aachen together. P/W's uncle, Eng. Sauer, Technical Director at the A.E.G. in Berlin, was also instrumental in his obtaining permission to view the experiments.

The generating apparatus was housed in a small brick building four meters square and three meters high. On one side of the building was a window one meter wide, and 50 cm. high. P/W was unable to look through this window as it was made of quartz glass and some form of metal was also distributed around the glass so as to prevent stray radiations.

At a distance of 200 meters from the side of the building that contained the quartz glass window was placed a small wooden crate with live guinea pigs in it. The spectators were first permitted to inspect the crate and the live creatures. Everyone was then requested to move back behind some white ropes so placed that they were safely protected, in a position even with the side of the building. A Dr. Schuetze then entered the small brick building and switched on the apparatus. No one was permitted to enter this building other than Dr. Schuetze, who remained inside the building as long as the apparatus was in operation. A humming noise could be heard similar to that made by a generator running at high speed. The ray was invisible. After about ten minutes, Dr. Schuetze turned the apparatus off and the spectators were then permitted to examine the box which contained the guinea pigs.

P/W inspected the guinea pigs closely. Not a sign of life was present. Even when a lighted match was held close to their noses, they showed no signs of life. Dr. Schuetze told P/W that the rays had destroyed the white corpuscles of the blood and had thus caused sudden death. P/W never again saw nor heard of any other such experiments. [...]

[See document photo on p. 3059.

This is another report (from an apparently very knowledgeable and trustworthy source) that indicates scientists were producing, projecting, and testing intense particle beams as potential weapons by early 1939, before the war even started.]

12. Atom-Smashing Experiments

Preamble. PW is 18 years old and comes from LUDWIGSHAFEN. After 8 years of public school, he attended an electric trades school for 3 years, working at the same time as radio and electro-technical student at the IG FARBEN plant in LUDWIGSHAFEN. At the end of this time PW was chosen "Reichssieger" as the result of his outstanding showing in the "Facharbeiterpruefung," a national examination for all technical students who have completed their training period. He was awarded a book on electricity, autographed by HITLER, and 8 semesters of tuition-free university study. In Nov 43 he went to HEIDELBERG, where he continued to work in the mornings for IG FARBEN, at their plant in that city, studying afternoons and evenings at the university.

Working in the so-called Ausweichwerk II of IG FARBEN as an electro-technician, PW's above-average skill aroused the interest of the chief engineer, as well as of other experts, and he was allowed to watch some highly secret experiments being conducted at the time. PW was used as an electrician on transformers and condensers, which were part of the experimental equipment.

In April 1944 PW left HEIDELBERG to put in his RAD time. After 3 months he returned to LUDWIGSHAFEN, worked for a short time at the IG FARBEN plant there, and was then inducted into the Army, 27 July 44.

Experimental Station, IG FARBEN, HEIDELBERG. The experiments discussed here were first conducted on a small scale in LUDWIGSHAFEN, and transferred in July 43 to the experimental station at HEIDELBERG, located at GSGS 4416/U3/695917. 100 workers, including 20 electricians, technicians, and engineers who worked daytimes only, were employed.

Security. Every two weeks a lecture was given by Ing RAITHEL impressing on all those working on the experiment the necessity of secrecy and the severity of punishment for security violations. Two electricians arrested appr 15 Dec 43 were never heard of again. It was rumored that they had talked and had been executed immediately.

The plant was enclosed by a three and a half m high wire fence charged with 1200 volts of electricity. Fifty police dogs roamed the area at night.

12. Atom-Smashing Experiments (Continued)

New Location? On 12 Nov 44, some three and a half months after his induction, PW returned from SCHWETZINGEN to the Station. At that time PW went to the kitchen and spoke to some of his old friends, making a date for the following Sunday with an old girl friend from the office. When he returned on 19 Nov the main guard at the gate told him that the station had moved. The girl did not appear for the date. PW doubts that the station could have been moved at such a short notice and has no explanation for the statement of the guard. PW noticed that the sidewalk around the first building was torn up and remembers the guard vaguely mentioned FREIBURG/Breisgau as a possible new location.

Experiments. The experiments involved a large, elaborate atom-smashing apparatus, the main features of which were four "Spruchpole" (positive) and one "Fangpol" (negative), each about 6 m high. Liberated protons were conveyed through a quartz tube to the Spruchpole, from which they were "fired" at an object placed on a quartz plate up to 800 m distant. This resulted, according to PW, in the complete disintegration of the object.

The first two experiments of this kind which PW witnessed took place in Dec 43 and Jan 44. In one, a 10 cm cube of steel (grade ST0012) was disintegrated within four-tenths of a second. The object in the second experiment was water, contained in a large quartz tube, tilted so that the "rays" would strike the largest possible surface. The water disappeared in two-tenths of a second.

The most spectacular experiment was conducted early April 1944, when some 75 rats were made to disappear in the same way. The experiment was photographed from the quartz-enclosed observation tower, and PW claims there was no trace of smoke or flame, nor did any ashes remain on the iron plate. His explanation of this apparent violation of the laws of physics is that the rats were somehow reduced to a gas, which was absorbed by the iron plate.

PW's Evaluation. PW doubts that the principle involved in the experiments described above could be adapted to military use in less than two years. The apparatus is extremely complicated and far too large and cumbersome to be moved readily. However, he concedes the possibility that during the eight months which have elapsed since he witnessed the experiments, further progress may have been made.

Personalities. The following men were connected with the experiments at HEIDELBERG:

FISCHER, Ewald	Ing
ETELFSEN	Dipl Ing
RAITHEL	Dipl Ing

DETAILED INTERROGATION REPORT

I. SOURCE

Name : SCHNETTLER, Karl
Rank : Unteroffizier
Unit : PANZER 33
Captured : 1 Dec 44, DIFFERTEN
Interrogation : 6824 DIC (MIS), 2 Mar 45

II. PREAMBLE

An 18 year old technician from LUDWIGSHAFEN. At first, he confirmed his previous story, as given in Report 2/32 (see NOTE, below). He was then questioned as to his technical knowledge of electronics, and it was found that he could not answer even elementary questions on the subject. He then stated that his original story was false.

PW now states that he was never, for any length of time, associated with a German University, or TECHNISCHE HOCHSCHULE, and that he cannot give information concerning the University of HEIDELBERG.

Although it is believed that PW is telling the truth, it is felt that his information should not be given a high reliability rating.

The information contained in this Report has been obtained at this Hq with the assistance of the Technical Liaison Division Office of the Chief Signals Officer, ETO.

Reliability : C-5

(NOTE: This Report should be read in conjunction with Mobile Field Interrogation Unit No 2 PW Intelligence Bulletin No 2/32, dated 30 Jan 45. See para 12, entitled "Atom-Smashing Experiments").

III. ATOM-SMASHING LABORATORY

A. Location

Ref Map: GERMANY 1: 25,000 GSGS 4414
Sheet 6416, FRANKENTHAL, Revised Oct 44

Photo Ref: ACIU Interpretation Report K 3228, 2 Oct 44

5021 0050 PW stated that the experiments described in Report 2/32 (see NOTE, above) were carried out in an underground structure, located at MR, in the I.G.FARBEN Plant at LUDWIGSHAFEN.

In Sep 44, PW heard that the Experimental Station was to be moved to an unspecified location in either HEIDELBERG, or FREIBURG/Breisgau.

B. Description (See Appendix "A")

The laboratory consisted of a concrete underground shelter, approx 50 meters long, 25 meters wide, and 8 to 10 meters high. Concrete walls were between 75 cms and 1 meter thick. The shelter was entered at ground level, but was not visible from the air.

Figure C.38: Detailed Interrogation Report 6824 DTC (MIS) M. 1075: Atom-Smashing Laboratory. 13 March 1945. [AFHRA folder 519.6501-2 1945; AFHRA A5730, frames 0488–0492]

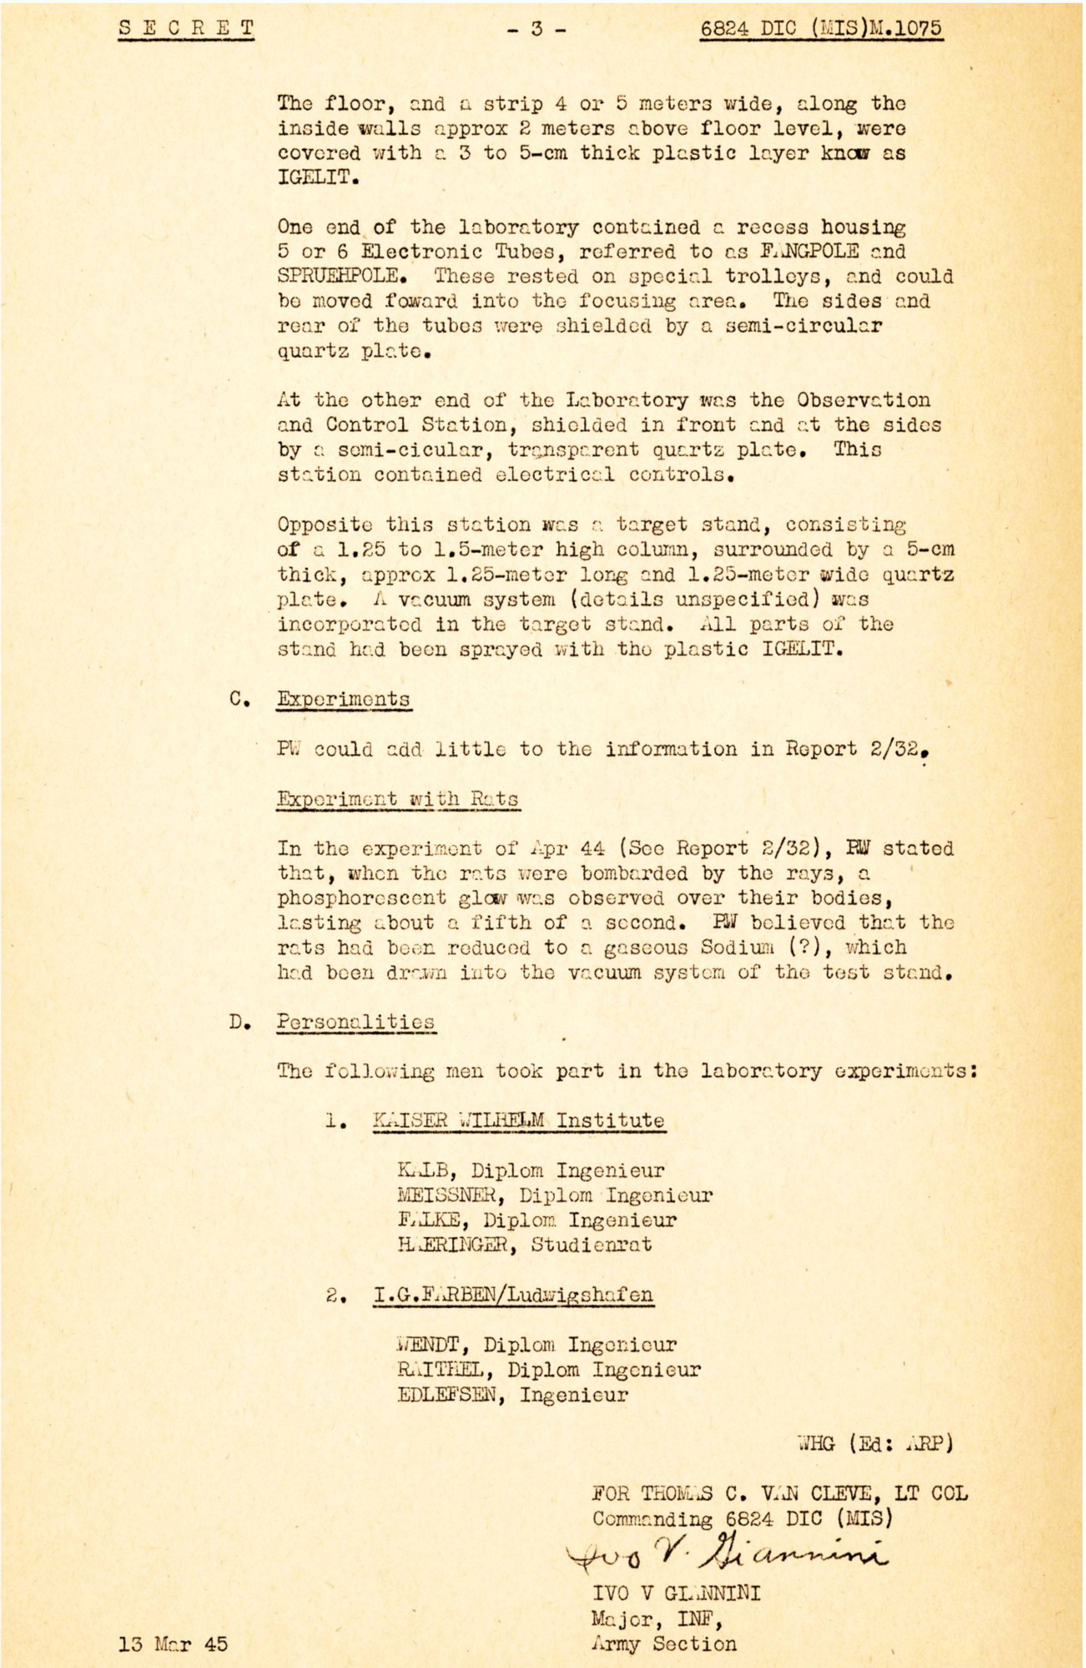
AFHRA folder 519.6501-2 1945



SECRET - 3 - 6824 DIC (MIS)M.1075

The floor, and a strip 4 or 5 meters wide, along the inside walls approx 2 meters above floor level, were covered with a 3 to 5-cm thick plastic layer know as IGELIT.

One end of the laboratory contained a recess housing 5 or 6 Electronic Tubes, referred to as FANGPOLE and SPRUEHPOLE. These rested on special trolleys, and could be moved foward into the focusing area. The sides and rear of the tubes were shielded by a semi-circular quartz plate.

At the other end of the Laboratory was the Observation and Control Station, shielded in front and at the sides by a semi-cicular, transparent quartz plate. This station contained electrical controls.

Opposite this station was a target stand, consisting of a 1.25 to 1.5-meter high column, surrounded by a 5-cm thick, approx 1.25-meter long and 1.25-meter wide quartz plate. A vacuum system (details unspecified) was incorporated in the target stand. All parts of the stand had been sprayed with the plastic IGELIT.

C. Experiments

PW could add little to the information in Report 2/32.

Experiment with Rats

In the experiment of Apr 44 (See Report 2/32), PW stated that, when the rats were bombarded by the rays, a phosphorescent glow was observed over their bodies, lasting about a fifth of a second. PW believed that the rats had been reduced to a gaseous Sodium (?), which had been drawn into the vacuum system of the test stand.

D. Personalities

The following men took part in the laboratory experiments:

1. KAISER WILHELM Institute

   KALB, Diplom Ingenieur
   MEISSNER, Diplom Ingenieur
   FALKE, Diplom Ingenieur
   HAERINGER, Studienrat

2. I.G.FARBEN/Ludwigshafen

PW Intelligence Bulletin 2/32. Atom-Smashing Experiments. 30 January 1945. [NARA RG 165, Entry NM84-79, Box 1916]

The first two experiments of this kind which PW [German prisoner of war] witnessed took place in Dec 43 and Jan 44. In one, a 10 cm cube of steel (grade ST0012) was disintegrated within four-tenths of a second. The object in the second experiment was water, contained in a large quartz tube, tilted so that the “rays” would strike the largest possible surface. The water disappeared in two-tenths of a second.

The most spectacular experiment was conducted early April 1944, when some 75 rats were made to disappear in the same way. The experiment was photographed from the quartz-enclosed observation tower, and PW claims there was no trace of smoke or flame, nor did any ashes remain on the iron plate. His explanation of this apparent violation of the laws of physics is that the rats were somehow reduced to a gas, which was absorbed by the iron plate.

[See document photos on pp. 3060–3061.]

Detailed Interrogation Report 6824 DTC (MIS) M. 1075: Atom-Smashing Laboratory. 13 March 1945. [AFHRA folder 519.6501-2 1945; AFHRA A5730, frames 0488–0492]

In the experiment of Apr 44 (See Report 2/32), PW stated that, when the rats were bombarded by the rays, a phosphorescent glow was observed over their bodies, lasting about a fifth of a second. PW believed that the rats had been reduced to a gaseous [form], which had been driven into the vacuum system of the test stand.

[See document photos on pp. 3062–3066.]

[This seems to be a later report of the testing of intense particle beams as potential weapons, describing experiments from December 1943 through April 44. If the description of the effects was accurate, the results were quite impressive, and the technology had clearly advanced a great deal since the 1937–1939 experiments described in the previous reports. Even so, such a particle beam weapon would have required a huge power source, which would have made it impractical for most military applications during the war, and may explain why it was never deployed.

Judging from several reports discovered in Walther Gerlach’s files by the U.S. Alsos Mission, in 1944 there were a number of very active projects aimed at developing and testing weapons based on particle accelerators that produced high-energy beams of electrons, ions, and/or X-rays [NARA RG 319 Entry NM3-82A, Box 6, Folder ALSOS G-20]. Gerlach was closely tied to the physics community, the Reich Research Council, and the SS, and he appears to have been appointed the chief scientific official responsible for funding and evaluating all or at least many of the particle beam weapon projects. Please see the following pages for a few examples from these reports.]

über die Sitzung des Kuratoriums am 6. Mai 1944 in Berlin und über die Sitzung eines Ausschusses des Kuratoriums am 15. August 1944 in Ainring.

I.) Sitzung 6. Mai 1944.

Der Vorsitzende begrüßt die Mitglieder des Kuratoriums die Herren Egerer, Esau, Fennel, Geist, Georgii, Heisenberg, Heuser, Hollnack, v. Loßberg, Seifert, Tams

und als Gäste die Herren Kulenkampff, Schiebold, Schumann (RMfRuK), Spengler, Rößler, Widerö.

1. Die Diskussion des Vorschlags von Prof. Schiebold, Röntgenleistungen bis zu 100 (oder mehr) Röntgen pro sec. in Abständen bis zu 10 km von der Röhre unter Verwendung einer Röhre mit einer besonderen Großflächenanode zu erzeugen, deren Verwirklichung eine Hauptaufgabe der Forschungsstelle der Luftwaffe Großostheim sein sollte, führte noch nicht zu einer endgültigen Klärung der Realisierbarkeit. Nach einer Abhandlung von Prof. Kulenkampff, Jena, über das Verhalten von 10 bis 100 Mill. Volt - Röntgenstrahlen errechnet sich eine aufzuwendende Leistung in der Röhre von der Größenordnung 10^5 bis 10^7 KW, um in 1 bis 2 km Entfernung 10 r/sec zu erreichen, was für lange Zeit technisch nicht erreichbar ist. Dazu fehlen sämtliche Unterlagen für die Erzeugung der Spannung, der Leistung und den Bau der Röhre.

   Dieses Ergebnis steht in starkem Widerspruch zu den von Prof. Schiebold vorgetragenen Rechnungen. Da ein Versuch, die Diskrepanz durch Aussprache in der Sitzung zu klären, scheiterte, wurde festgesetzt: Die Herren Schiebold und Kulenkampff tauschen ihre Ansichten schriftlich aus; sollte eine einheitliche Auffassung beider Herren nicht zustande kommen, so wird der Vorsitzende eine Sachbesprechung zwischen beiden Herren und einigen wenigen Mitgliedern des Kuratoriums abhalten. Es wird angenommen, daß dieses in 3 Wochen der Fall sein kann.

2. Die 1200 KV-Anlage wird nicht in Großostheim aufgestellt, da von einer Untersuchung von Kathoden- und Röntgenstrahlen in diesem Spannungsgebiet keine grundsätzlich neuen Erkenntnisse erwartet werden können. Es wird vorgeschlagen, diese Anlage einem anderen Forscher z.B. Prof. Gehrtsen zur Durchführung atomphysikalischer Untersuchungen zur Verfügung zu stellen. Die Forschungsführung veranlasst das Weitere.

3. Da der für die 1200 KV-Anlage vorgesehene Bau in Großostheim auch für die 2000 KV-Anlage ausreicht, wird letztere, zurzeit in Hamburg lagernde Anlage dorten aufgestellt. Sie soll zur Erzeugung von Neutronen und Herstellung radioaktiver Indikatoren benutzt werden, da zur Durchführung bedeutungsvoller technischer und medizinischer Forschungsarbeiten eine Vermehrung der in Deutschland vorhandenen Aktivierungsanlagen dringend erforderlich ist.

II.) Sitzung am 15. August 1944.

Der Vorsitzende gibt zunächst einen Überblick über die Vorgänge während der 3 Monate seit der letzten Sitzung, welche zu der Verzögerung der Einberufung dieser Sitzung geführt haben. Prof. Schiebold hatte entgegen der Verabredung in der Kuratoriumssitzung nicht seine damals gemachten Mitteilungen schriftlich festgelegt, sondern auf mehrfaches Bitten hin erst am 14. Juli eine umfangreiche Denkschrift eingereicht. Am 17. Juli gab Prof. Kulenkampff eine Erwiderung, am 29. Juli Schiebold eine Ergänzung und Entgegnung.

Die umfangreiche Denkschrift Schiebolds wird von diesem an mehreren Stellen als noch nicht endgültig bezeichnet, da er glaubt, noch eine ganze Reihe von Problemen weiter theoretisch bearbeiten zu müssen. Er erwartet hiervon entscheidende Ergebnisse für die Beurteilung der Realisierbarkeit des Projektes.

Nach Ansicht des Vorsitzenden genügten jedoch die von Schiebold und Kulenkampff gegebenen Rechnungen und abschätzenden Überlegungen, um die Frage der Größenordnung der erforderlichen Röhrenleistung mit solcher Sicherheit anzugeben, daß die Zweckmässigkeit der weiteren Behandlung des Projektes und die Frage seiner militärischen Verwendbarkeit entschieden werden können.

Der Vorsitzende hatte daher eingeladen die Herren: Georgii, Geist, Heisenberg, Kulenkampff, v. Loßberg, Schiebold, Seifert. Oberst Geist hatte als Vertreter Herrn Schumann geschickt, Prof. Heisenberg war verhindert. Dr. Spengler war als Gast anwesend.

- 3 -

Die Besprechung betraf 3 Hauptpunkte.

1.) Welche Dosis und welche Dosisleistung ist erforderlich?

Die in den verschiedenen Berichten von Schiebold gegebenen Zahlen schwanken zwischen 5 und 600 R/sec für die Leistung und 800 R bis 3000 R für die Energie zur Erzielung von Hautschäden. Eine Unsicherheit in der Umrechnung von Energie auf Leistung liegt nach Schiebold in dem unbekannten Zeitgesetz. Es wird festgestellt, daß genaue Unterlagen für Schädigung des Menschen bei Gesamtbestrahlung überhaupt nicht vorhanden sind. Es herrscht Einmütigkeit darüber, daß für die folgende Betrachtung eine Größenordnung von 600 R während einer Bestrahlungszeit von 30 sec, also 20 R pro sec als wahrscheinlich richtig für eine sichere spontane Dauerschädigung zu Grunde gelegt werden soll.

(Nachträgliche Bemerkung des Vorsitzenden: Gesetzt den Fall, daß die Schieboldsche Idee ausführbar und eine starke Schädigung eines Fliegers erzielt wäre, so würde der Feind nach ganz kurzer Zeit die Art der Abwehrwaffe erkannt haben. Es dürften sich dann Mittel finden, den Flieger im Flugzeug recht weitgehend zu schützen.)

2.) Nach Seite 21 der Schieboldschen Denkschrift vom 14. Juli 44 soll eine Großflächenanode ein quantitativ anderes Abstandsgesetz für die Ausbreitung der Röntgenstrahlen liefern als eine punktförmige Anode, insbesondere soll nach Seite 5 in kleineren Abständen die Intensität größer sein als nach dem einfachen quadratischen Abstandsgesetz berechnet wird.

Zunächst wird festgestellt, daß das quadratische Abstandsgesetz immer einen idealen Grenzfall darstellt. Prof. Schiebold erklärt, daß ihm dieses bisher nicht bekannt war.

Die anwesenden Physiker stellen fest, daß die punktförmige Anode unter allen Umständen und in allen Entfernungen am günstigsten ist. Dieses folgt auch aus einer richtigen Auswertung der von Schiebold benutzten Formeln.

Die Frage der Großflächenanode betrifft lediglich das Problem der Unterbringung der erforderlichen Leistung in der Röhre. Für alle Rechnungen über die erreichbaren Strahlenleistungen kann also die punktförmige Anode zu Grunde gelegt werden, umsomehr als in den beabsichtigten Wirkungsentfernungen (R größer als r/ϑ, r = Radius der Anode, ϑ = Emissionswinkelbereich) der Unterschied zwischen kleiner und großer Anode bis auf minimale Bruchteile eines Prozent verschwindet. Nur in kleinen Abständen liefert die Großflächenanode ganz wesentlich weniger als die punktförmige. (Gerechnet auf gleiche Leistung) Hieran wird auch durch andere Vorschläge Schiebolds, z.B. gekrümmte Anode, gar nichts geändert. Prof. Schiebold schließt sich diesen Feststellungen nicht vollinhaltlich an.

Prof. Schiebold weist auf verschiedene Effekte hin, welche nach seiner Ansicht wesentlich günstigere Ergebnisse erwarten lassen, als aus den Rechnungen von Kulenkampff zu folgern ist; z.B. daß der Nutzeffekt einer großen Anode besser sein könne oder dass die Beachtung der spektralen Verteilung und ihrer

-4-

602

Figure C.44: Notes from 1944 meetings of Walther Gerlach with Ernst Schiebold, Helmuth Kulenkampff, Rolf Wideröe, Gerhard Schumann, and others involved in the development of particle beam weapons. - 4 -

Änderung längst des fortschreitenden Strahles höhere Leistungen bringen kann oder dass die Streustrahlung im Flugzeug die Leistung am Orte der gewünschten Wirkung erhöhe. Auf die Bitte, diese Ansicht näher zu begründen, antwortet Prof. Schiebold, daß er jetzt hierzu keine Stellung nehmen könne. Der Vorsitzende spricht sein Befremden darüber aus, daß über ein Jahr nach der Bekanntgabe der Idee von Prof. Schiebold noch grundlegende Fragen für die Beurteilung, ob die Idee vernünftig ist oder nicht, noch immer nicht bearbeitet sind; nach seiner Ansicht hätten diese Fragen vor einer Bekanntgabe überlegt werden müssen, zumal Prof. Schiebold jetzt ihnen entscheidende Bedeutung beimißt, nachdem seine ursprüngliche Begründung (Abstandsgesetz der Grossflächenanode) weggefallen ist. Eine Idee, wie die Änderung des Nutzeffektes bei geänderter Größe der Anode, entbehrt so sehr jeglicher Grundlage, daß eine Besprechung derselben abgelehnt wird.

Prof. Georgii weist scharf zurück, daß in jeder neuen Besprechung von Prof. Schiebold neue Ideen ohne theoretische oder zahlenmäßige Begründung vorgebracht werden; durch eine solche Behandlung würde jede abschließende Überlegung unmöglich gemacht.

Prof. Kuhlenkampff zeigt überschlagsmäßig, daß die Berücksichtigung der neuen Vorschläge von Schiebold (spektrale Verteilung und hieraus zu ziehende Folgerungen) an der Größenordnung der berechneten Effekte nichts ändert, dass vielmehr für die meisten Effekte schon der günstigste Fall gerechnet ist.

3.) Frage der Herstellung der erforderlichen Energi~~e~~en und Leistungen.

Als erforderliche Leistung wird angegeben:

Schiebold: für 25 000.000 Volt und Großflächenanode mit 2 m Durchmesser bei spezifischer Belastung derselben bei 100 Watt/cm^2 werden gefordert 314.000 KW zur Erreichung von 850 R/sec in 1 km Entfernung. Die richtige Umrechnung auf die Entfernung von 5 km liefert bei dieser Leistung in der Röhre eine Strahlungsleistung von 0,11 R/sec. (In dem Schieboldschen Bericht steht 1,1 R/sec. offensichtlich ein Schreibfehler.)

Kulenkampff: Für 25.000.000 Volt, unabhängig von der Art der Anode und dem Bau der Röhre werden gefordert zur Erzielung einer Strahlungsleistung von 10 R/sec in

1 km	Entfernung	230.000 KW
2 km	"	11.000.000 KW
3 km	"	etwa 52.000.000 KW

- 5 -

Trotz langer Diskussion wird eine endgültige Einigung über die zahlenmäßige Rechnung nicht erreicht. Der Vorsitzende stellt fest, daß an der geforderten Größenordnung von 1 000 000 KW nicht zu zweifeln ist. Es sind also die Fragen aufzuwerfen, ob eine solche Leistung auch während kleiner Zeiten (Größenordnung 1 Minute) zur Verfügung steht und in einer Röhre untergebracht werden kann. Als Spannung wird 25.000.000 Volt angenommen. Weitere Fragen betreffen die für einen militärischen Einsatz erforderliche Zahl von Stationen und die Zahl der ganz kurzzeitig hintereinander erforderlichen Bestrahlungen einer Dauer der oben genannten Größenordnung.

Prof. Kulenkampff weist noch einmal nachdrücklich daraufhin, daß für die von Oberst v. Loßberg geforderten Wirkungsentfernungen bis zu 10 km, mindestens aber 6 bis 8 km die erforderlichen Leistungen von einer ganz anderen Größenordnung sind. (Weit über 100.000.000 KW bei 25.000.000 Volt).

Nach einiger Diskussion wurde darauf verzichtet, genau festzustellen, welche Angaben dem Chef der Technischen Luftrüstung, Oberst Diesing (RLM), gemacht wurden. Prof. Schiebold weist auf eine Angabe seines 1. Gutachtens hin, daß für Wirkungen von 1 bis 2 km bei 2.000.000 Volt 100.000 KW erforderlich seien. Dies ändert aber nichts daran, daß die von dem Vorsitzenden zur Diskussion vorgeschlagene Grössenordnung von 1.000.000 KW die Grundlage für die jetzige Diskussion sein muss.

Die Diskussion ergibt mit aller Klarheit, daß weder die Herstellung der Spannungen, der geforderten Leistung, noch die Herstellung einer Röhre in Betracht gezogen werden kann, da sämtliche technischen Unterlagen hierfür fehlen und da aus Bekanntem nur gefolgert werden kann, daß solche Leistungen bei solchen Spannungen und der Bau von Röhren mit der erforderlichen Wärmeabfuhr für lange Zeit unerreichbar sein werden. An diesem Urteil hat sich seit den ersten Vorschlägen von Prof. Schiebold nichts geändert. Es wird ausdrücklich festgestellt, daß auch kein Weg gesehen wird, auf welchem experimentell eine gewisse Annäherung an das Ziel erreicht werden kann.

Eine Prüfung, ob die Gesetze, mit welchen Prof. Kulenkampff rechnet, in dem beabsichtigten Spannungsbereich richtig sind, wird mit der Entwicklung der Elektronenschleudern einsetzen. Prof. Kulenkampff weist aber darauf hin, daß die von ihm benutzten Gesetze sämtlich aus der schon mehrere Jahre vorliegenden physikalischen Literatur stammen und dass nicht eigene Ideen von ihm verwendet wurden.

Der Vorsitzende stellt abschließend fest, daß:

1.) kein physikalischer Effekt ersichtlich ist, welcher die bei richtiger Diskussion übereinstimmenden Rechnungen von Schiebold und Kulenkampff größenordnungsmäßig ändert;

2.) keine Aussicht besteht, den Plan von Prof. Schiebold für militärische Zwecke der Luftfahrt nutzbar zu machen;

3.) auch für militärische Anwendungen auf kurze Entfernungen (Größenordnung einige 100 m) apparative Aufwendungen erforderlich sind, für welche heute technische Unterlagen noch nicht vorliegen.

Kurzer Bericht über die Arbeiten, welche vom Unterzeichneten und seinen Mitarbeitern im Institut für röntgenologische Roh- und Werkstofforschung im Rahmen des Forschungsauftrages DE 6224/0109/43 seit 20. April 1943 durchgeführt wurden.

1. Ausarbeitung der Grundlagen des Projektes für die Besprechung mit dem Herrn Generalfeldmarschall am 20.4.43.
2. Verschiedene Denkschriften und Berichte an GL/St mit Einzelheiten meiner Planung und Vorschläge für die Durchführung.
3. Mitarbeit bei den technischen und organisatorischen Vorarbeiten über die Auswahl des Platzes und der Einrichtung der Versuchsstelle Groß Ostheim.
4. Exposé über die Bedeutung des Wideröeschen Strahlentransformators für die vorliegenden Pläne und maßgebende Beteiligung an Verhandlungen mit Herrn Dr. Wideröe.
5. Ausarbeitung der Pläne betr. Auf- und Ausbau der großen Halle in Gr. Ostheim, gemeinsam mit dem Büro Prof. Tamms (Arch. Sander) und den zuständigen Herren vom Luftgau XII.
6. Aufstellung der Pläne für Installation, Telefonanlage usw. für die zunächst vorgesehenen Laboratoriumsbaracken und den Ausbau der Unterkunftsräume.
7. Versuch zur Einrichtung wissenschaftlicher Arbeitsräume nebst Feinmechanikerwerkstatt, zunächst mit dem Inventar des Instituts für röntgenologische Roh- und Werkstofforschung zum Zwecke der Vornahme dringlicher Vorversuche. Diese Einrichtungen wurden auf Veranlassung der Forschungsführung inzwischen wieder aus Ostheim entfernt.
8. Schulung der aus der Truppe herausgezogenen wissenschaftlichen und ingenieurtechnischen Mitarbeiter.
9. Zusammenstellung der für die Arbeiten wichtigen Literatur und Ausarbeitung eines zusammenfassenden kritischen Berichtes über die bisherigen Ergebnisse ~~auch~~ auf dem Gebiete der Physik durchdringen der Röntgen- und Gammastrahlen, sowie Elektronen.
10. Aufstellung von Inventarlisten und Geräten für die erste Einrichtung von Laboratorien und Werkstätten.
11. Beschaffung der 1,2 Mill. Voltanlage vom Hamburger Staat.
12. Bestellung einer 2,2 MV-Röntgenanlage bei der Fa. C.H.F.Müller in Hamburg.
13. Entwicklungsauftrag an die Firma C.H.F.Müller-Hamburg über einen 15 MV-Strahlentransformator Bauart Wideröe..
14. Beschaffung von Laboratoriumsbedarf und Geräten aus Beutestellen der Luftwaffe.
15. Wissenschaftliche Arbeit theoretischer Natur über die Ausbreitung und Schwächung harter Röntgenstrahlen in Luft variabler Zusammensetzung, Dichte und Temperatur für verschieden hohe Primärenergien
16. Projektierung einer Großanodenröntgenröhre nach eigenen Vorschlägen.
17. Projektierung einer Anlage zur Erzeugung hoher Spannung und großer Stromstärke nach dem Kaskadenprinzip auf Grund eines eigenen DRP.

Leipzig, den 4. Mai 1944. Prof. Dr. E. Schiebold.

Ausbreitung eines Elektronenstrahls in Luft

1. Reichweite R. Der Energieverlust der Elektronen setzt sich zusammen aus dem Energieverlust durch Ionisationsprozesse = J und durch Bremsstrahlungserzeugung = S:

$$\frac{dE}{dx} = \frac{dU}{dx} = J + S \, .$$

Man kann hieraus eine Reichweite R auf zweierlei Weise definieren:

a) Meist wird eine mittlere Reichweite R_0 angegeben, die aus der Summe der Energieverluste J + S unter der Annahme bestimmt wird, dass diese Energieabnahme für jedes Elektron des Strahles gleichmässig längs der Bahn erfolgt. Wie in meinem Bericht über die Bremsstrahlung energiereicher Elektronen angegeben ist (Seite 6), erhält man so

$$R_0 = \frac{\varkappa}{J} \cdot \ln\left(1 + \frac{U}{\varkappa}\right) \qquad \text{mit } \varkappa = U \cdot \frac{J}{S} \qquad (1)$$

Zahlenmässig ist für Luft (Dichte ρ = 0,00129)

$k = 11{,}0 \cdot 10^7$ (U in eVolt)

$J = 2{,}3 \cdot 10^3$ bis $3{,}1 \cdot 10^3$ eVolt/cm, langsam steigend im Energiebereich $U = 5 \cdot 10^6$ bis $100 \cdot 10^6$ eVolt

Damit ergeben sich die Werte in der zweiten Reihe der folgenden Tabelle 1.

Tabelle 1. Mittlere Reichweite R_0 und maximale Reichweite R_{max} von Elektronen in Luft

Energie U	10	20	30	50	75	100	200 $\cdot 10^6$ eVolt
R_0	42	72	100	150	200	240	370 m
R_{max}	43	79	113	180	260	335	650 m

b) Für den vorliegenden Zweck scheint es mir aber richtiger zu sein, zunächst nur den Energieverlust durch Ionisation J zu berücksichtigen, weil der Energieverlust durch Bremsstrahlungs-Erzeugung S in einem leichten Element und bei nicht allzu grossen Energien keine sehr grosse Rolle spielt, vor allem aber wegen des Umstandes, dass der Energieverlust S nicht

Bericht
über
die Arbeiten mit dem Strahlentransformator bis 15.9.1944
(1. Zwischenbericht).

---

1) Nach Fertigstellung des ersten 15 MV Transformators und einer für etwa 30 KV geeigneten Elektronenspritze könnten die ersten experimentellen Untersuchungen etwa Mitte Juli beginnen. Die Elektronen wurden damals nach meinem Vorschlag von außen eingeschossen und eine richtige Strahlführung mittels elektrostatischer Felder sowie durch Schwenkung der gesamten Elektronenspritze erreicht. Unser Arbeitsprogramm war daher das folgende:

a) Untersuchung über das Einführen der Elektronen.

b) Erhöhung der mittleren Strahlleistung mittels einer magnetischen Linsenwicklung.

Nach einigen Vorversuchen gelang es, die Elektronen etwa 1 - 2 mal in der Beschleunigungsröhre herumzuführen, wenn der Magnet mit Gleichstrom magnetisiert wurde. Der Transformator wurde dann mit Wechselstrom erregt und die Suche nach harten Röntgenstrahlen mit Hilfe eines Röntgenstrahlmeßgerätes (Zählrohr aus Plexiglas nach Troost mit einer Empfindlichkeit von etwa 10^{-6} r/sec) begonnen. Gleich im Anfang wurde dabei eine Strahlung festgestellt, die, obwohl sie nicht von der Antikathode ausging, doch anscheinend die Eigenschaften der gesuchten harten Strahlung besaß (ziemlich scharf begrenztes Bündel). Als wir nähere Untersuchungen machen wollten, brannte leider die Glühkathode der Elektronenspitze durch. Als diese, sowie auch einige weitere technische Störungen, beseitigt waren, zeigte sich sofort, daß die Strahlung, entgegen unserer ersten Annahme, von den 30 KV Elektronen der Elektronenspritze herrührten.

Obwohl das Einschußverfahren durch Änderungen der Ablenkplatten usw. noch günstiger gestaltet werden konnte, wurden in den folgenden Tagen keine harten Röntgenstrahlen festgestellt. Aus diesem Grunde wurde am 7.August das folgende neue Arbeitsprogramm festgelegt.

a) Um die richtige Ausbildung der magnetischen Felder zu untersuchen, soll sofort eine Elektronenspritze nach Kerst eingebaut werden (eine entsprechende Glasröhre war schon im Mai von Herrn Kuntke bestellt worden).

b) Die Nachweismethode der Strahlen sollte empfindlicher gemacht werden, sodaß einzelne Quanten noch beobachtet werden könnten.

c) In der Zwischenzeit wollte Dr. Kollath die bisherigen Einschußverhältnisse noch genauer untersuchen.

Die letztgenannte Untersuchung ergab, daß man durch eine verbesserte Strahlführung offenbar die Elektronen zum mehrmaligen Umlaufen in der Röhre bringen könnte (die Röhrenwände leuchteten dabei auf dem ganzen Umfang gleichmäßig stark auf), mit dem Strahlenmeßgerät ließen sich aber auch in diesem Falle keine harten Röntgenstrahlen nachweisen.

Nach der Ansicht von Dr.Kollath waren die Vakuumverhältnisse nicht so gut, daß eine Elektronenbeschleunigung möglich gewesen wäre. Während der Versuche war das Vakuum(noch vor der Röhrenzuleitung gemessen) etwa 4 bis 20.10^{-5} Torr. Die späteren Versuche haben diese Vermutung voll bestätigt, eine Beschleunigung ist bei 50 Hz offenbar nur möglich, wenn das Vakuum $<$ 1.10^{-5} Torr beträgt.

Bei Weiterführung der Einschußversuche muß somit zunächst die Röhre für günstigere Vakuumbedingungen umgebaut werden und insbesondere die schwenkbare Verbindung der Elektronenspritze mit der Beschleunigungsröhre unbedingt vermieden werden.

2) .....

Herrn
Professor Dr. W. Gerlach,

(13b) München 22
Ludwigstrasse 17

Sehr geehrter Herr Professor,

wir haben bei unseren Arbeiten eine Beobachtung gemacht, die ich Ihnen möglichst schnell berichten möchte:

Während des letzten Monats haben wir mit ziemlich starken Strahlintensitäten gearbeitet. Während dieser Zeit habe ich, nach unseren bisherigen Messungen gerechnet, wohl einige r bekommen (Dr.Kollath etwas mehr). Diese Dosen sollten viel zu klein sein, um biologische Wirkungen hervorzurufen.

Bei der letzten Blutuntersuchung zeigten sich indessen bei mir deutliche struktuelle Veränderungen der Leucocyten. Dr.med.Kruse (Krankenhaus St.Georg) hat uns untersucht und verfolgt den weiteren Verlauf dieser Erscheinungen.

Die Erscheinung kann nur dadurch erklärt werden:

1) Daß unsere Meßinstrumente doch zu wenig angeben (überschlägige Berechnungen ergeben den Faktor 3 zu wenig)
2) Daß unsere Strahlung wesentlich stärkere biologische Wirkungen haben muß, als man annehmen sollte.

Wir bitten Sie, dies Erscheinungen den anderen mit ähnlichen Geräten arbeitenden Herren mitzuteilen, um Schäden durch Unvorsichtigkeiten zu vermeiden. Wir selbst werden sofort Maßnahmen zur Herabsetzung der Strahlengefahren vornehmen.

Mit freundlichen Grüßen

R. Wideröe

P.S. Wir erwarten in den nächsten Tagen den Besuch von Prof.Dänzer und Gentner, die verschiedene Fragen über die Elektronenschleudern mit uns besprechen wollen.

G-187. W. Schmitz and W. Wiebe. Technical Experiences in the Construction of the Bonn Cyclotron. 1942.

Brief description of some features of the Bonn cyclotron which has been put into partial operation. Because of financial restrictions, magnet has 50 cm pole diameter. It is air cooled, 2000 windings, 3 amp/mm^2, 10,000 Gauss. Temperature rise after 1 hour operation = 50^o which increases resistance of copper 15%. Homogeneity between the cylindrical poles = 1.6; with shimming, field strength is 20% higher in the slits (5 mm). Descriptions also of the current regulator, the high frequency generator, and the Dees.

G-204. Walther Bothe. Radiation Shielding Walls. 1943.

Analysis of shielding required for a cyclotron (8 MeV) operated with deuterons and the operator 8 m from the apparatus.

G-205. Walther Bothe. The Research Tools of Nuclear Physics. 1943.

General semipopular lecture delivered before German air force personnel describing the various particle accelerators used in nuclear physics including cascade transformers, electrostatic generators, Van de Graaff accelerators, cyclotrons, rheotrons, and also the uranium pile. Concludes with plea for needed personnel.

G-209. Walter Dällenbach. Patent Application and General Correspondence with the German Patent Office on a Particle Accelerator. 1943.

This is not a complete report on a particle accelerator but rather a patent application on certain features of the proposed unit.

[Dällenbach was a Swiss physicist, but the German government funded his own research center, Forschungsstelle D, for the development of high-energy particle accelerators during the war [Dippel 1992; Burghard Weiss 1996].]

G-232. H. Lange and K. Fink. The Possibility of Saving Material in Building Cyclotron Magnets. 1943.

A general manual on the design of 15,000 gauss cyclotron magnets giving data on pole diameters (ranging from 100 to 120 cm), pole gap (20 to 40 cm) and the efficiency of various materials as windings. Special emphasis is laid on the use of aluminum wire as a substitute for copper.

G-247. Otto Baier. Report on the Design of the Vacuum Tank and Oscillator for the Cyclotron of the Physics Section of the German Post Office Department Research Institution. 1944.

Vacuum tank with radiation chamber, ion source and probe, deflector, electrode dees and their mounting, are described, also the oscillator and the flange connecting the oscillator tank with the main vacuum tank, and the mechanism for introduction of the target. Plans for this equipment are illustrated.

G-255. Siegfried Flügge. Observations Concerning the Theory of the Rheotron. 1944.

A rheotron is a particle accelerator built on the principle of a magnetic field variable in time producing a circular electric field. Charged particles with very high energies result if the magnetic power increases until the desired energy of the particle is reached, and if the accelerated particle keeps a circular path of the same diameter. Equations are computed for the electron path, energy increase, stability of the path, and axial and radial oscillations. The path traveled by the electrons is figured to be several 100 km. Interactions with the vacuum atmosphere are considered.

[Richard Gans and Heinz Schmellenmeier did considerable work on rheotrons during the war [Waloschek 2004, pp. 33–64].]

G-282. H. Salow. The High Frequency Circuit for a Cyclotron. 1944.

A method to achieve a high potential (100 kV or more) with the least high frequency energy output, allowing for a resonance wave length range of 26–30 m for the accelerated particles, and a capacity of the dee electrodes of about 100 cm is discussed. Various possible high frequency systems are examined, namely the L-C circuit (inductance L completing the capacity to an oscillating circuit), concentric double circuits, and a shielded double circuit system. Energy losses of the circuit and coupling of the feeding line are considered.

G-284. Ernst Schiebold. On the Possibility of Biological Effects of Shortwave X Rays or Gamma Rays, Using Specially Constructed X-Ray Tubes, at Long Distances. Lecture Given at the Meeting of the Kuratorium of the German Air Force Research Institute Grossostheim. 6 May 1944.

This is a detailed discussion of the possibilities of using x irradiation and electrons in radiological warfare over long distances. The report is not based on experiments but entirely on estimations. Construction of x-ray tubes, scattering and absorption in air, intensity decrease due to various factors, dosage, etc. are discussed.

G-286. W. Schmitz and A. Weckesser. Investigations of High Frequency Currents for Construction of a Large Cyclotron. 1944.

In very large cyclotrons the potential distribution in the acceleration gap between the dees is no longer constant. In order to obtain information on the voltage increase to be expected, measurements of potentials were conducted on a model of decreased size with wave length shortened accordingly. An improved wiring and oscillator system are designed. A procedure is developed for calculation of the effect of the increase in potential on the particle path.

G-292. W. Wiebe. Consideration for Construction of a 80 Million Volt Cyclotron. 1944.

Considerations on construction of a large cyclotron include calculations concerning magnetic field focusing, relation between magnetic field and particle path, relative increase in mass and resonance, and design of vacuum chamber and voltage source. [...] For production of the desired particle path a magnetic field of 17,610 maximal and of 7450 gauss minimal strength is calculated to be needed. The diameter of the poles is figured to be 175 cm, iron weight of the magnets is anticipated as 1500 tons. The path of the deuterons would have a total length of 2500 m, deuterons of 80 MeV and alpha particles of 160 MeV can be produced.

FA 002/0384. Letter from Rudolf Fleischmann to Maurer. 10 February 1943. Archive of Deutsches Museum Munich.

Fleischmann visited Mentzel on Jan. 28 and heard that Esau had been put in charge of nuclear physics by the Reichsmarschall. From Siemens man, he heard that Siemens has been constructing since four years a large cyclotron with 1.60 meter diameter. He did not say for whom. There can be hardly any doubt that it is for an organization of the armed forces. Is this the large cyclotron for WaF?

FA 002/0362. Letter from Maurer to Rudolf Fleischmann. 12 January 1943. Archive of Deutsches Museum Munich.

[...]The two people from the Reichspost were here. Their magnet gives only 16,000 Gauss, 160 mm gap, diameter 1080 mm. They hope to get 10 million volt.

FA 002/0362. Letter from Maurer to Rudolf Fleischmann. 5 March 1943. Archive of Deutsches Museum Munich.

Esau and Bothe have left Paris. Maurer was present at a discussion between Esau and Bothe. Maurer pointed out to Bothe the egotistic behaviour of the firm of Siemens and that he regrets that Fleischmann as nuclear physicist has to go empty handed whereas the Reichspost and Siemens are allowed to build with mere beginners. Maurer asks what is going to happen with the second Siemens magnet. [...] Bothe is no end fed up.

[After the war, Allied investigators wrote several reports about particle accelerators they found in Germany or former German-controlled territories.]

BIOS Misc 77 = NavTechMisEu 331-45. *European Electron Induction Accelerators.* [https://www.cdvandt.org/BIOS-Miscell-77.pdf]

SUMMARY

Betatrons, induction electron accelerators for the production of high energy x-radiation, were under development in Germany during the war and are also to some extent at present. This work is reviewed for the most part and details are given on the constructional features of 6 and 15 million volt betatrons and on the theory and design of 15 and 200 million volt betatrons. The smaller units, especially the Siemens 6 Mv are quite successful and more advanced than comparable American units. While no large machines were actually built the projected 200 Mv Wideröe design introduces new features of value. Betatron patent ideas are reviewed.

I. Introduction.

A. History of Betatron Developments on Continent.

The first work on the subject of electron induction acceleration which appeared in Europe was the doctoral dissertation of Rolf Wideröe of Bergen, Norway, which appeared in 1927 and was published in print the following year. [...]

Developments on the continent have been based on Wideröe's work. The basic ideas were by Steenbeck in his patents of 1937 [...] in which the necessary properties of the magnetic accelerating and guiding fields are formulated.

An induction electron accelerator was built on these principles and tried with success, it is claimed, although the intensities of radiation produced were only of cosmic ray intensity order. [...]

The betatron development was carried out by three separate groups. One was the Megavolt Versuchsanstalt (MVA) or Megavolt Research Association which worked under the guidance of Dr. Wideröe. Siemens and AEG also had projects. MVA laid plans for a 15 Mv and a 200 Mv accelerator. The former was begun early in 1944 and brought to successful completion in the fall of the same year. The design of the 200 Mv accelerator was completed about this time and the construction work turned over to the Brown Boveri firm in Heidelberg. Recent investigation showed that MVA had no further connection with this project.

The basic ideas underlying the design of these two induction accelerators were published by Wideröe in two papers. These discuss the special problems involved such as axial and radial stabilization by properly designed guiding fields, injection and extraction of electrons, the useful load of the apparatus, the maximum electron filling of the acceleration chamber, dependence on injection voltage (using auxiliary lens system), the stabilization of electronic orbits with electrical lenses, especially for high radiation energies, the effects of gas molecules, technical transformer construction details for high energy production, and finally the fields of application of the betatron: cancer treatment, radiography, and nuclear physics.

In collaboration with the design work of Wideröe, a considerable amount of theoretical work has been carried out by Touschek. This is known to have been of invaluable aid in the development of the 15 Mv accelerator. Further theoretical work has also been done by Touschek in the starting of electrons in the accelerator. [...]

BIOS 1730. *Industrial Electrical Research in Germany.* pp. 91–94, 133–136.

A betatron having an output of about 15 MeV, .01 Röntgens per second at 1 metre, is in working condition at this place [M.V. Forschungs-Vereinigung]. An outline of the design in Fig. 39 has been prepared from sketches from a drawing at Wrist.

The following particulars were provided by Touschek:–

Operating frequency	50 cycles per second.
Orbit radius.	14 cms.
Core details:–	
Length	92 cms.
Height.	56 cms.
Radius of centre core.	11 cms.
Pole pieces have inner dia.	27.6 cms.
” ” ” outer dia.	29.8 cms.
Air gaps of centre core.	2 cms.
” ” between pole pieces.	6 cms.
Cross section of main yokes.	13 x 32 cms.
Weight:–	
Iron.	816 Kg.
Copper.	188 Kg.
Magnetic circuit particulars:–	
Max. induction in core.	11,300 gauss.
Average induction with orbit	7,400 gauss.
Induction at orbit (R=14 cms).	3,700 gauss.
Max. induction in yoke.	10,200 gauss.
Main Coils:–	
Current.	48 amps. R.M.S.
Voltage.	4,780 volts.
KVA.	230
Ampere turns, peak	19,000
Volts per turn.	17.1
Cooling.	By air.
Copper losses.	500 Watts
Iron losses, core	156 Watts.
” ” poles.	150 Watts.
” ” yoke.	960 Watts.
Power factor correction condenser.	33 MFD at 5000 volts.

The core is built up from low-loss transformer steel; a loss figure of 1.1 watts per Kg, at 10,000 gauss, 50 cycles per second, was quoted. Ten different sizes of radial laminations, each 0.35 mm. thick, are used in the core. A lower grade of transformer steel is used for the yoke.

The “doughnut” is of glass (Pyrex type), built up from two semicircular moulds, and is continuously pumped. The internal surfaces are aquadag coated. The resistance of the aquadag coating measured across a diameter was understood to be 30 ohms.

An approximate sketch of the gun, and target carried on the gun is given in Fig. 40. The current at injection has an average value of 0.125 mA. and a peak value of 12.5 mA, approximately. It was stated that about 10% of the injection current arrived in the orbit. An injection pulse time of about 2.0 microseconds was aimed at, but the actual time achieved was about 250 microseconds. With the present betatron up to 30 MEV has been obtained.

The characteristic at the orbit was stated to be H = K r^{-6}. The expansion of the orbit is by magnetic saturation; expansion onto the target takes place after about 60 degrees from flux zero.

In order to utilise the maximum change of A.C. flux, a D.C. biasing scheme is proposed, using a D.C. bias winding embracing the pole pieces in the manner shown in Fig. 41. The bucking transformer shown is to compensate for the induced e.m.f. caused by A.C. flux which links with the added D.C. winding.

A scheme for getting electrons out of the chamber was briefly described. Two additional sets of electrodes would be placed in the doughnut. The first electrode at a potential of some kV would upset the stability conditions so that electrons would leave the stable orbit, and be directed to a pair of electrodes (plates) which would deflect the electrons further from the orbit and focus them into a beam, which then leaves the doughnut in a linear manner. The apparently optimistic figure of 60% was mentioned as the number of electrons which would be removed from the orbit and given a linear path.

[...]

Two betatrons were seen at the Erlangen works of the Siemens Reiniger concern, one in running condition and the other very nearly complete. Both are for providing X-rays corresponding to 6 MEV.

The essential particulars of the completed betatron are as follows:–

Output—6 MEV; X-ray output 0.2 röntgens per minute
—15 gr. radium at 1 metre.

A.C. supply frequency.	550 cycles/sec.
Orbit radius.	8.3 cms.
Target radius.	11.0 cms.
Injection radius	6.3 cms.
Injection current (mean) (5 milliamps possible)	1.0 milliamp.
Voltage at injection.	4000/5000
Injection time.	10^{-5} second.
K.V.A. to main coils (100 amps 3 KV. to give 6 MEV).	300
Expansion time.	2 x 10^{-5} second.
X-ray time.	5 x 10^{-6} second.
Vacuum (see curve Fig. 69)	3 x 10^{-5} mm.
Current in orbit	5 x 10^{-7} amp.
Approx. characteristic at orbit.	H $r^{-1/2}$
H at orbit.	1400 gauss.
Total losses, approximately.	3 KW.
Copper losses.	800 watts.

Doughnut; Ceramic in two main disc sections, metallised
and soft soldered; pumped, (see Fig. 68)
Iron circuit; overall dimensions 26" x 8" x 19" approx.

For details of pole pieces (see Fig. 68) the outer annulus comprises about 2000 suitably shaped laminations, as A, bent to fit to the required diameter. Inside A is a core section B built up of radially displaced laminations, similarly bent. The central section C is made up from small packets of strip laminations about 2 to 3 mm. wide, total of about 11,000 strips. All of these laminations are of ordinary silicon steel 0.3 mm. thick. Shims G of magnetic dust materials are place between B and a ribbed bakelite spacer H, possibly to allow for cooling. The assembly of pole pieces, etc., and the doughnut comprises one unit which can be inserted or withdrawn from the main core and coil assembly without disturbing the latter.

The orbit is expanded into the target by auxiliary coils energised from a thyratron circuit, which serves to discharge a 2 MFD condenser at 1000 volts through these said coils. The circuit arrangement is shown in Fig. 70.

The main magnetic circuit is water cooled, the conductors being a number of strands of Ltz wire wound round brass tubing through which water flows.

Siemens Reiniger have another betatron of similar physical size and rating nearly completed; it is for operation on a 50 cycles supply.

S.R.W. have apparently paid appreciable attention to conditions at injections and had built a model to study the effect of various types of gun. A constant field is evidently applied to the model and the adjustable fluorescent screen; a number of viewing windows are provided in the chamber.

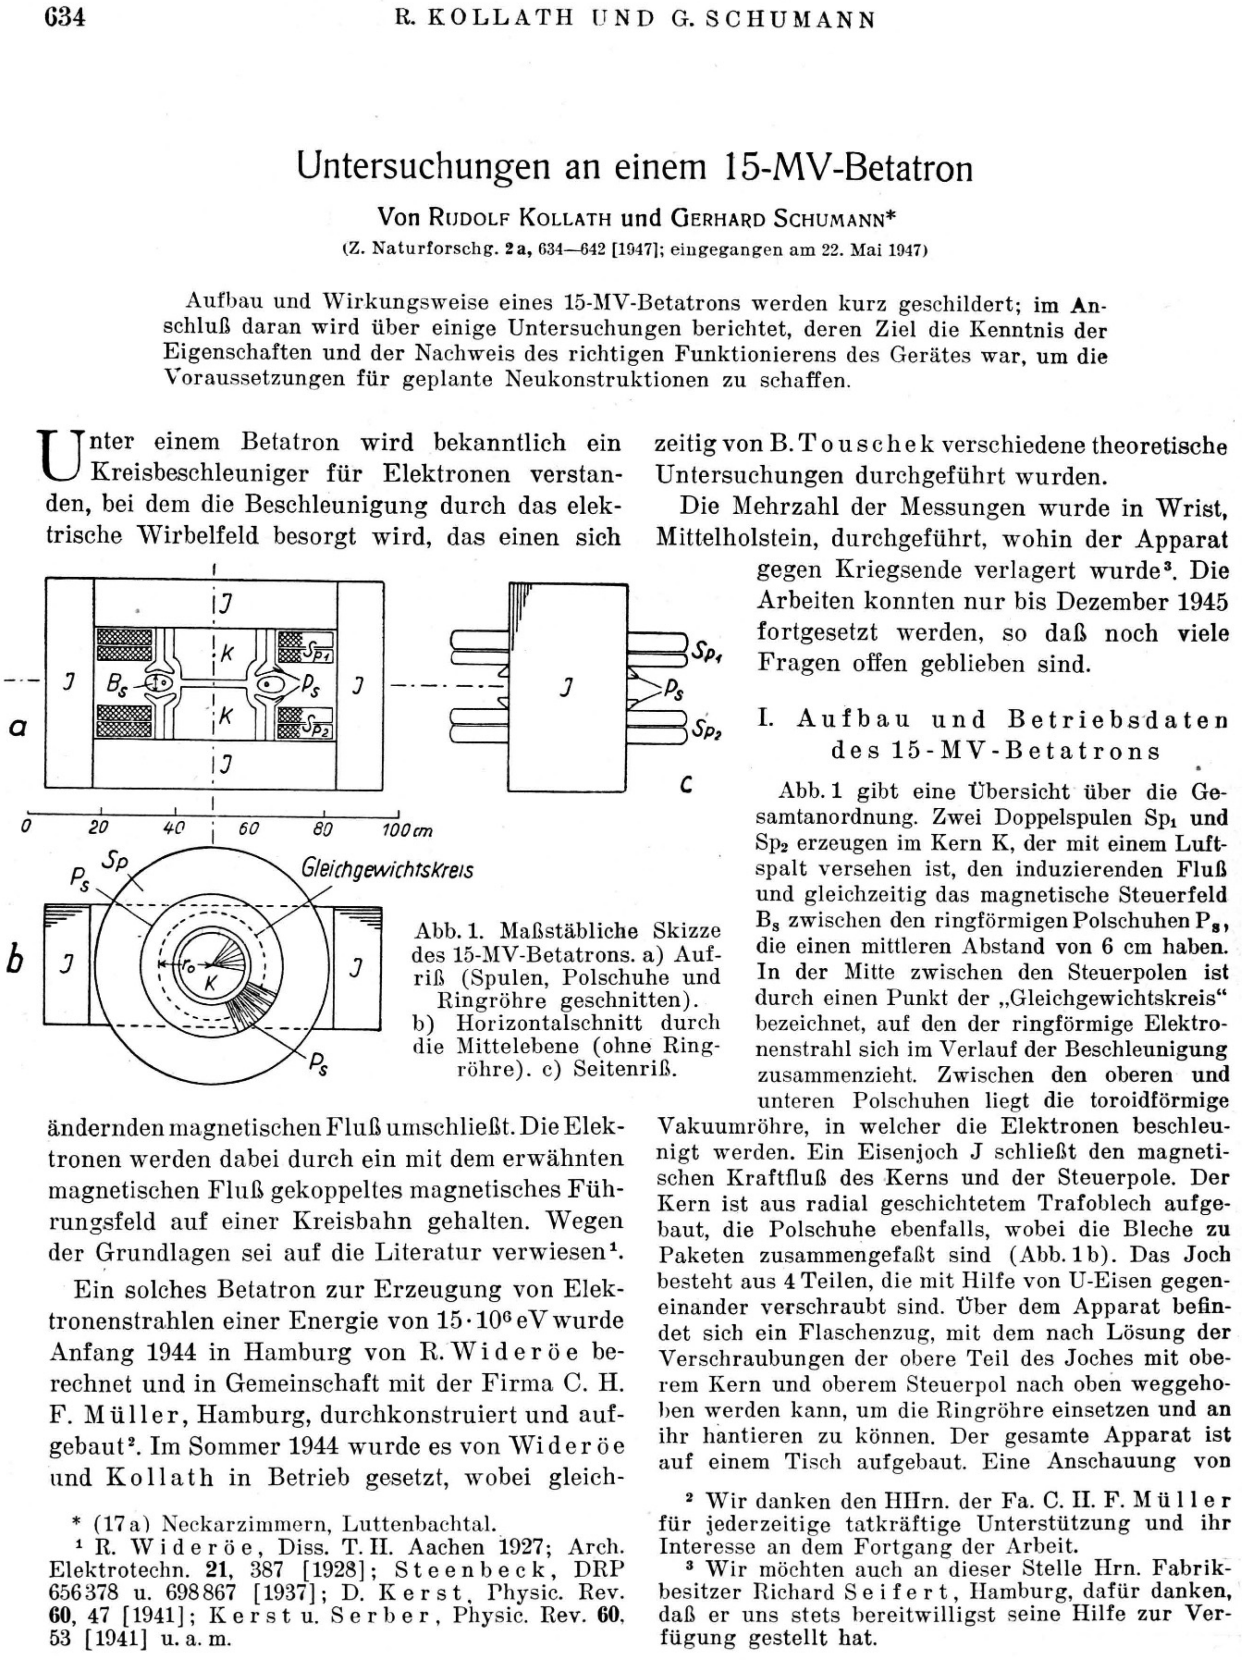
After the war, two scientists who worked on the 15 MeV betatron published a paper about it:

Rudolf Kollath and Gerhard Schumann. 1947. Untersuchungen an einem 15-MV-Betatron. *Zeitschrift für Naturforschung* 2a:634–642 [http://zfn.mpdl.mpg.de/data/Reihe_A/2/ZNA-1947-2a-0634.pdf].

See Fig. C.57.]



Untersuchungen an einem 15-MV-Betatron

Von Rudolf Kollath und Gerhard Schumann*

(Z. Naturforschg. **2a**, 634—642 [1947]; eingegangen am 22. Mai 1947)

Aufbau und Wirkungsweise eines 15-MV-Betatrons werden kurz geschildert; im Anschluß daran wird über einige Untersuchungen berichtet, deren Ziel die Kenntnis der Eigenschaften und der Nachweis des richtigen Funktionierens des Gerätes war, um die Voraussetzungen für geplante Neukonstruktionen zu schaffen.

Unter einem Betatron wird bekanntlich ein Kreisbeschleuniger für Elektronen verstanden, bei dem die Beschleunigung durch das elektrische Wirbelfeld besorgt wird, das einen sich ändernden magnetischen Fluß umschließt. Die Elektronen werden dabei durch ein mit dem erwähnten magnetischen Fluß gekoppeltes magnetisches Führungsfeld auf einer Kreisbahn gehalten. Wegen der Grundlagen sei auf die Literatur verwiesen[1].

Abb. 1. Maßstäbliche Skizze des 15-MV-Betatrons. a) Aufriß (Spulen, Polschuhe und Ringröhre geschnitten). b) Horizontalschnitt durch die Mittelebene (ohne Ringröhre). c) Seitenriß.

Ein solches Betatron zur Erzeugung von Elektronenstrahlen einer Energie von $15\cdot10^6$ eV wurde Anfang 1944 in Hamburg von R. Wideröe berechnet und in Gemeinschaft mit der Firma C. H. F. Müller, Hamburg, durchkonstruiert und aufgebaut[2]. Im Sommer 1944 wurde es von Wideröe und Kollath in Betrieb gesetzt, wobei gleichzeitig von B. Touschek verschiedene theoretische Untersuchungen durchgeführt wurden.

Die Mehrzahl der Messungen wurde in Wrist, Mittelholstein, durchgeführt, wohin der Apparat gegen Kriegsende verlagert wurde[3]. Die Arbeiten konnten nur bis Dezember 1945 fortgesetzt werden, so daß noch viele Fragen offen geblieben sind.

I. Aufbau und Betriebsdaten des 15-MV-Betatrons

Abb. 1 gibt eine Übersicht über die Gesamtanordnung. Zwei Doppelspulen Sp_1 und Sp_2 erzeugen im Kern K, der mit einem Luftspalt versehen ist, den induzierenden Fluß und gleichzeitig das magnetische Steuerfeld B_s zwischen den ringförmigen Polschuhen P_s, die einen mittleren Abstand von 6 cm haben. In der Mitte zwischen den Steuerpolen ist durch einen Punkt der „Gleichgewichtskreis“ bezeichnet, auf den der ringförmige Elektronenstrahl sich im Verlauf der Beschleunigung zusammenzieht. Zwischen den oberen und unteren Polschuhen liegt die toroidförmige Vakuumröhre, in welcher die Elektronen beschleunigt werden. Ein Eisenjoch J schließt den magnetischen Kraftfluß des Kerns und der Steuerpole. Der Kern ist aus radial geschichtetem Trafoblech aufgebaut, die Polschuhe ebenfalls, wobei die Bleche zu Paketen zusammengefaßt sind (Abb. 1b). Das Joch besteht aus 4 Teilen, die mit Hilfe von U-Eisen gegeneinander verschraubt sind. Über dem Apparat befindet sich ein Flaschenzug, mit dem nach Lösung der Verschraubungen der obere Teil des Joches mit oberem Kern und oberem Steuerpol nach oben weggehoben werden kann, um die Ringröhre einsetzen und an ihr hantieren zu können. Der gesamte Apparat ist auf einem Tisch aufgebaut. Eine Anschauung von

1. PERSONAL DATA

Subject was born in 1891 in JANOWICE, Poland and studied engineering in POSEN and BERLIN. He devoted most of his life to research, ranging from mechanics to atom smashing. He had his own laboratories in WARSAW and POSEN and claims to have patented 86 inventions so far. In 1927 he was called by the President of Poland and received a secret assignment which he is unwilling to describe in any greater detail other than that it concerned research on war materials.

Source developed an apparatus to radio-activate metals, especially mercury. He claims that the rays produced by this machine black out radio waves, offset magnets, and have a deadly paralyzing effect on humans. He claims this machine is especially important in that it destroys the function of the gyroscope. Source declares his willingness to disclose all details of this machine and demonstrate it at his laboratory in the TYROL. He states that the secret of this machine has not fallen into German hands.

2. ADMINISTRATIVE DATA

Source was arrested by 103 MP Det, arrived this CENTER 24 May 45 on authority G-2, Seventh Army. Documents: blueprints and patent for tire-changing apparatus; papers on radio-activation of metals; and on invention of a special ignition coil.

3. KNOWLEDGE BRIEF

a. Details on radio-activation of metals, and atom smashing.

b. Tire-changing apparatus.

c. Other inventions.

4. INTERROGATION PLAN

Interrogation will be withheld until an expert in his field can exploit prisoner's knowledge.

5. COMMENTS AND RECOMMENDATIONS

It is suggested that subject be interrogated by a technical expert. The recipients of this report are requested to submit special briefs of any subject upon which this man should be interrogated.

[Igor Witkowski received significant publicity for his claims that a mysterious German device called "die Glocke" or "the Bell" was built and tested in Poland during World War II [Cook 2001; Witkowski 2010, 2011, 2012, 2013; https://igorwitkowski.com/english.html]. Witkowski's claims about the Bell have been repeated by numerous books, television programs, and websites and have taken on a life of their own. As far as I am aware, Witkowski's personal statements are the only source of information that the Bell even existed, let alone what its historical and technical details were, and he has never presented any documents to substantiate his claims.

All of Witkowski's original books and articles are in Polish. Only a few of his books have been translated into German or English [Witkowski 2010, 2011, 2012, 2013]. Another Polish author, Bartosz Rdułtowski, analyzed the complete history of Witkowski's Polish writings and statements in considerable detail, and made what sounds like a very credible case that Witkowski simply invented the story of the Bell [Rdułtowski 2012b]. Even in the most charitable interpretation, the story of the Bell came to Witkowski from a source, who got it from another source, who likely got it from another source, none of whom were scientists, so one would expect the technical details to have gotten garbled along the way, as in the children's game of telephone.

The above interrogation report on Raman Janiszewski (see also Fig. C.58) has a few details that seem similar to some of those in Witkowski's Bell story: a device was developed in Poland during the war, it involved mercury, and it produced various strange and dangerous effects in its surroundings. The Janiszewski interrogation report does not say that the device was bell-shaped, or give any other details that have been claimed by Witkowski. It is not clear if the similarities are a coincidence, or if Witkowski used actual information such as that from Janiszewski and then added many fictional elaborations to the story, or if there may actually be some historical reality to the story of the Bell after all.

Even limiting the discussion to the Janiszewski interrogation report, it is not clear how credible Janiszewski was, how his device worked, and whether it would actually produce any of the variety of effects that he attributed to it. The Manhattan Project foreign intelligence officials, George Davis and Francis Smith, seemed to take his claims seriously though.

Can other information on Raman Janiszewski's background, his research, and his interrogations be located? Can any other similar documents be found?]

Paul E. Todd, U.S. Air Forces in Europe, U.S. Air/Air Ministry Branch, to Assistant Chief of Staff, A-2, Headquarters, USAFE. 19 November 1946. Activities Report (11 through 16 November 1946). [AFHRA C5088 electronic version p. 957]

[...] (4) X-Death Ray report completed and forwarded, thru channels, to Assistant Chief of Staff, A-2, USAFE, A.D.I. (Science), Mr. Gerrard, and Joint Intelligence Bureau, Major Rushmore. [...]

[What German X-ray directed energy weapon was important enough and sufficiently well developed by the end of the war in Europe that the U.S. Army Air Forces was still writing a report on it 18 months after the war ended, and forwarding that report to high levels?

Can a copy of this report be located now?]

C.2 Electromagnetic Pulse

[Several Allied intelligence reports described the development and successful testing of some sort of German electromagnetic pulse (EMP) weapons capable of knocking out the electrical systems of engines, or other electrical devices. A nuclear explosion will generate a large EMP, but the German EMP generators described in the reports appear to have been non-nuclear. Many countries now have non-nuclear EMP weapons in their arsenals.]

Extract of Information—Source: Letter #1172/EM, 11 Mar. 1944 to Col. H. A. Kenyon from Col. A. J. P. Le Bel. [**AFHRA A1263 frame 213**]

Notable Incidents.

a.) On November 19, on the outskirts of Lens at 5:30 P.M. a British Plane was downed with no apparent struggle. The plane was flying normally when all of a sudden, it pitched to the ground and was crushed.

b.) English pilots, interned in Switzerland, have declared that as they flew over the Eastern part of France their apparatus had been deranged—also—reports have pointed to the fact that centers for the transmission of these rays have been installed at Ardennes.

These two facts lead us to surmise that the Germans have experimented with their secret weapon and that these rays or waves are capable of hampering Electric parts of plane motors and to disturb the apparatus on board.

Report Received from G-2, 12 April 1944 and Filed in Ski Site File.

Allen W. Dulles. 1 September 1944 OSS report. [**Allen W. Dulles Papers: Digital Files Series, MC019-09, Public Policy Papers, Department of Special Collections, Princeton University Library. https://findingaids.princeton.edu/catalog/MC019-09_c015 Correspondence_General_English_1942-1974_and_undated 1940s 19440901_0000031626.pdf**]

Sorrel reports that Breakers messenger on his last trip to Switzerland around July 10th, referred to a new secret weapon. This weapon is reported to consist of an apparatus by which the operation of motors in planes and tanks can be interrupted through some kind of secret long-distance interference by rays or waves. At the same time it was reported that experiments with this secret weapon had been successfully concluded and that production was to be started.

History of the Counter Intelligence Corps, Volume XX, Germany Overrun–Part I. March 1959. pp. XX-61–XX-62 [NARA RG 319, Entry UD-1080, Box 6].

Secret Weapons

That the Nazis had hoped to win the war by secret weapons became evident to XVIII Corps CIC Agents with the capture and subsequent interrogation of Werner Piel, a special air courier of secret technical devices for the Luftwaffe.

Piel claimed that the German laboratories that had produced V-1 and V-2 missiles had also perfected an array of diabolical devices that needed only large scale production before they could be used against the Allied armies.

The strangest and most fascinating of these secret weapons was described as a “secret ray” that would paralyze any vehicle to a halt. The instrument, which the Germans called “Adlergeraet” or “Eagle Apparatus,” was demonstrated to Piel and others at a proving ground near Danzig in July 1944. Piel asserted that an automobile driven across the testing area was brought to a complete standstill by the ray as if the spark of the vehicle had suddenly failed.

The mechanism was principally adapted for use by the Luftwaffe in night fighting. Planes equipped with the Adlergeraet could allegedly trail behind an adversary, bring him in range and then drop him from the sky by “konking out” his engines without firing a single round. This was the theory. No estimate of actual effectiveness had been made.

Piel’s connection with the secret devices was largely during the six weeks prior to his capture when he ferried the equipment from Berlin to Glasshuette, where the finished devices were made, and then delivered them to aircraft manufacturers.

Before CIC completed the interrogation of the ray-obsessed Piel, the Agents learned the current disposition of the informant’s organization, the Air Force High Command, Chief of Technical Division for Air Armament Transport. Apparently, Allied bombing of Berlin had been so effective that this German technical air wing had to be split into two branches, one in Austria and the other along the Baltic sea.[80]

80. XVIII Corps (Abn) G2 Periodic Rpt Nr 9, Annex Nr 1, “CIC Notes,” dtd 5 May 45, in FUSA G2 Jnl and File, 7–8 May 45, L-558 (UNCLASSIFIED), (Departmental Records Branch, AGO, Alexandria, Va.)

[Note that the interrogation of Piel seems to indicate that advanced research projects associated with the Luftwaffe were largely centered in Berlin (until they had to be evacuated due to Allied bombing), the Baltic coast, and Austria. That agrees with many other documents that indicate that Berlin, the Baltic coast, and Austria were three of the areas that had especially large concentrations of high technology development during the war.]

Merillat Moses, Chief, Scientific Branch, U.S. Military Intelligence Service, to Major Francis J. Smith. 16 November 1944. Evaluation of Reports on Rays or Charges to Neutralize Aircraft Motors. [**AFHRA A1263 frames 129–130**]

1. The Military Intelligence Service is in receipt of various reports dealing with rays for stopping or neutralizing aircraft motors such as:

> a. An ultra-violet ray for stalling airplane motors is being worked upon hard, but as yet without practical success.
>
> b. Experiments were being made on another electrical apparatus whereby vehicles coming within its field could be stopped.
>
> c. The famous “Death Ray” is spoken of again and it is said that several airplanes have been made to fall in the neighborhood of this installation.
>
> d. The use of radio ray [that] emits wave that slows down the motors of Allied planes flying over region.
>
> e. In February it was reported that the Germans were working on some mechanism to stop aircraft motors.
>
> f. A source who states that he has done much work for the P.T.T. at Tempelhof in Berlin and for the Reichspostforschungsanstalt claims that 80% of their laboratory work is on aviation. A high official and an engineer there have informed him that they have completed a new A/A weapon which will be turned out in mass production in two or three months.
>
> g. Experiments with “Death Rays” were conducted by AEG-Siemenstadt Berlin at Tempelhof in 1939. Guinea pigs were killed at a distance of 200 meters.
>
> h. An individual employed “on electrical matters”, not named or otherwise described, told the prisoner that the Germans had for years been experimenting with these death rays.
>
> j. Experiments of which he knew, (1) destroying the functions of aircraft motors with induced magnetic fields, (2) exploding aircraft in the air by direct ultra-violet ray.
>
> k. This weapon which emits waves or rays based on piezo-electricity is a development of the death ray. It is known that tests were made in 1938 and that [at] a distance of eight hundred meters an automobile motor was successfully stopped.
>
> l. The Germans will use within the next three weeks new generator which is capable of stopping motors.

2. An hypothesis has been received stating that by use of rays or charges the atmosphere surrounding the airplane engine could be ionized, causing the ignition system to spark at joints and also where the insulation has been cracked or broken, thereby causing a short circuit of the spark plug.

3. Any evaluation or opinion you may be able to render on the existence or practicability of any rays or charges, to include probably type of emission, range, size of installation required, would be highly appreciated.

Headquarters, United States Strategic Air Forces [USSTAF] in Europe, Office of the Director of Intelligence, An Evaluation of German Capabilities in 1945. The Commanders Intelligence Digest. 19 January 1945 [AFHRA folder 519.635 1945 Intelligence Digest; AFHRA A5729 electronic version pp. 255 onward and 561 onward; NARA RG 319, Entry UD-1041, Box 27, Folder 925497]].

1. In the following paragraphs are listed the actual or potential weapons which the Germans may use against USSTAF operations in 1945. For the most part they include the so-called V weapons. No consideration is given to those for which there is lacking evidence of possible use for some time to come. [...]

5. MAGNETIC WAVE: The best information available is from very secret and reliable sources, and forces the conclusion that this weapon exists as a possibility. It is designed to cause failure of various electrical apparatus in aircraft. [...]

[See document photos on pp. 5338–5340.

Point 1 above suggests that there is significant evidence for those weapons that are then listed.

Point 5 shows that an EMP weapon was reported by "very secret and reliable sources."]

V. W. Petersen, Headquarters United States Strategic Air Forces in Europe (Rear), Office of the Director of Intelligence, to General George C. McDonald. 24 January 1945. Preliminary Report on Suspected Magnetic Ray. [AFHRA A1263 frames 141–142]

1. This is a preliminary report on investigation of the P-38 aircraft which flew sortie No. 3832 over Frankfurt and the interrogation of the Pilot, Lt. Hitt. Over this area the Pilot encountered a freakish condition which indicates that the enemy may be using some new device (suspected as being a magnetic ray) as a defence measure against our aircraft.

2. The Pilot made three passes over the target area which was the northern part of Frankfurt for the purpose of taking aerial photographs. He took a number of frames on his first two passes, at approximately 22,000 ft. and 20,000 feet, but on his third pass at 17,500 ft. he ran into trouble with his aircraft. At this time he was flying in a straight slightly climbing condition, no flak of any kind was encountered and no evasive action was taken during the whole time over the target area.

3. In beginning his third pass his instruments began acting up and his left engine became very rough. [...]

4. The other gauges and instruments which were affected included the fuel level gauges, gyro compass and the artificial horizon. The hands on the fuel level gauges started spinning in the same direction. The gyro compass was also spinning through 360^o revolutions. The Pilot caged the compass at three different times and after uncaging each time the compass continued to spin through 360^o revolutions. The artificial horizon was floating in a peculiar attitude so that it could not be used. [...]

8. The instruments on Lt. Hitt's ship continued acting up for a period of eight to ten minutes; after this time they appeared to be functioning properly. [...]

Taylor Drysdale, P/W and X Detachment, U.S. Military Intelligence Service, to Col. H. G. Bunker, Director of Technical Services, Hq. USSTAF (Rear). 25 January 1945. ETOIB/Ext No. 101. [AFHRA A1263 frame 148]

The following information was given by German P/W (W/T Specialist) on German Experiments with Remote Control of Automobile and Airplane Motors.

(This material was written originally by P/W in German and has since been translated into English.)

In the year 1934 successful experiments were made in Germany on the paralyzing of combustion in Automobile Engine viz. the stopping of the motors. Subject heard also last year from a Laboratory Engineer of the Weapons Office, that vehicles and motors could be stopped at a distance of 150 meters (about 166 yards).

An Engineer belonging to a Research Institute of the R.M.V. who attended these experiments, said that the same thing could be done with airplanes.

In 1938, two German Aircraft Plants were entrusted with the order to study motors for aircraft without electrical ignition.

Between Augsburg and Munich, experiments were made in driving an electric motor by wireless.

During the last experiments a small ventilator motor (in Augsburg) was set in motion by a dispatcher controlled in Munich. The power used by the dispatching station in Munich was reported to be very strong.

[Unfortunately none of the available reports on German EMP weapons give any technical details about how the weapons actually worked. If such weapons were indeed developed during the war, how exactly did they generate an EMP? What was their range?

Several countries now have non-nuclear EMP weapons [see for example Fig. C.59 and
https://apps.dtic.mil/dtic/tr/fulltext/u2/a332511.pdf
https://sgp.fas.org/othergov/doe/lanl/pubs/00326620.pdf
and additional scientific references cited at the end of
https://en.wikipedia.org/wiki/Explosively_pumped_flux_compression_generator].

Were these modern weapons derived from captured hardware, documents, or personnel from wartime German EMP programs?]

C.3 Lasers

[A laser (Light Amplification by Stimulated Emission of Radiation) produces light that all has the same wavelength and the same phase, which enables all of the optical power to be concentrated into just one wavelength or color instead of a broader spectrum, and also allows the beam to remain much more tightly focused than a normal beam of light can. (Because the laser light all has the same wavelength and phase unlike a normal light beam, constructive interference with itself keeps it on course, and destructive interference with itself prevents it from veering off course.) According to official histories, the idea of a laser was not proposed until the late 1950s by Charles Townes, Arthur Schawlow, and Gordon Gould, and the first laser was not built until 1960 by Theodore Maiman, all in the United States.[1] As the following documents illustrate, most of the discoveries and innovations that led to lasers were made much earlier by German-speaking scientists, and there is some evidence that German-speaking scientists may have even been the first to produce a working laser. Documents on the German-derived work were sent to the United States and may have directly contributed to the U.S. work in this field in the late 1950s and early 1960s. Much more archival research is needed to investigate the complete history and the true impact of work in this field by German-speaking scientists [Albrecht 2019; Bertolotti 2015; Lemmerich 1987].]

Walter Isaacson. 2007. *Einstein: His Life and Universe.* pp. 322–323.

Einstein used Bohr's model as the foundation for a series of papers in 1916, the most important of which, "On the Quantum Theory of Radiation," was also formally published in a journal in 1917.

Einstein began with a thought experiment in which a chamber is filled with a cloud of atoms. They are being bathed by light (or any form of electromagnetic radiation). Einstein then combined Bohr's model of the atom with Max Planck's theory of the quanta. If each change in an electron orbit corresponded to the absorption or emission of one light quantum, then—presto!—it resulted in a new and better way to derive Planck's formula for explaining blackbody radiation. As Einstein boasted to Michele Besso, "A brilliant idea dawned on me about radiation absorption and emission. It will interest you. An astonishingly simple derivation, I should say *the* derivation of Planck's formula. A thoroughly quantized affair."

Atoms emit radiation in a spontaneous fashion, but Einstein theorized that this process could also be stimulated. A roughly simplified way to picture this is to suppose than an atom is already in a high-energy state from having absorbed a photon. If another photon with a particular wavelength is then fired into it, two photons of the same wavelength and direction can be emitted.

What Einstein discovered was slightly more complex. Suppose there is a gas of atoms with energy being pumped into it, say by pulses of electricity or light. Many of the atoms will absorb energy and go into a higher energy state, and they will begin to emit photons. Einstein argued that the presence of this cloud of photons made it even more likely that a photon of the same wavelength and direction as the other photons in the cloud would be emitted. This process of stimulated emission would, almost forty years later, be the basis for the invention of the laser, an acronym for "light amplification by the stimulated emission of radiation."

Strahlungs-Emission und -Absorption nach der Quantentheorie;

von A. Einstein.

(Eingegangen am 17. Juli 1916.)

Als Planck vor 16 Jahren die Quantentheorie ins Leben rief, und seine Strahlungsformel aufstellte, schlug er folgenden Weg ein. Er berechnete die mittlere Energie $\overline{E}$ des Resonators in Funktion der Temperatur nach von ihm neu aufgestellten, quantentheoretischen Grundsätzen und bestimmte dann hieraus die Strahlungsdichte ϱ in Funktion der Frequenz ν und der Temperatur, indem er auf elektromagnetischem Wege die Beziehung zwischen Strahlungsdichte und Resonatorenergie $\overline{E}$ aufstellte:

$$\overline{E} = \frac{c^3 \varrho}{8\pi \nu^2}. \qquad 1)$$

Seine Ableitung war von beispielloser Kühnheit, fand aber glänzende Bestätigung. Es bestätigte sich nicht nur die Strahlungsformel selbst und der aus derselben berechnete Wert des Elementarquantums, sondern auch der für $\overline{E}$ quantentheoretisch berechnete Wert durch die späteren Untersuchungen über die spezifische Wärme. Es bestätigte sich somit auch die auf rein elektromagnetischem Wege gewonnene Gleichung 1). Unbefriedigend blieb es aber, daß die elektromagnetisch-mechanische Betrachtung, welche zu 1) führt, mit der Grundidee der Quantentheorie nicht vereinbar ist, und es ist nicht verwunderlich, wenn Planck selbst und alle Theoretiker, die sich mit der Materie befassen, unaufhörlich bemüht sind, die Theorie so umzugestalten, daß sie auf widerpruchsfreien Voraussetzungen beruht.

Seit die Bohrsche Theorie der Spektra ihre großen Erfolge erzielt hat, scheint es nicht zweifelhaft zu sein, daß die Grundidee der Quantentheorie festgehalten werden muß. Es scheint also die Einheitlichkeit der Theorie dadurch hergestellt werden zu müssen, daß die elektromagnetisch-mechanischen Betrachtungen, welche Planck zu der Gleichung 1) führten, durch quantentheoretische Betrachtungen über die Wechselwirkung von

Figure C.60: Albert Einstein first proposed the idea of stimulated light emission from atoms (amplification of the number of photons of light from atoms) in 1916 [*Verhandlungen der Deutschen Physikalischen Gesellschaft* (1916) 18:13–14:318–323].

Zur Quantentheorie der Strahlung

von **A. Einstein**.

Die formale Ähnlichkeit der Kurve der chromatischen Verteilung der Temperaturstrahlung mit dem Maxwell'schen Geschwindigkeits-Verteilungsgesetz ist zu frappant, als daß sie lange hätte verborgen bleiben können. In der Tat wurde bereits W. Wien in der wichtigen theoretischen Arbeit, in welcher er sein Verschiebungsgesetz

$$\varrho = \nu^3 \, f\left(\frac{\nu}{T}\right) \tag{1}$$

ableitete, durch diese Ähnlichkeit auf eine weitergehende Bestimmung der Strahlungsformel geführt. Er fand hiebei bekanntlich die Formel

$$\varrho = \alpha \, \nu^3 \, e^{-\frac{h\nu}{kT}} \tag{2}$$

welche als Grenzgesetz für große Werte von $\frac{\nu}{T}$ auch heute als richtig anerkannt wird (Wien'sche Strahlungsformel). Heute wissen wir, daß keine Betrachtung, welche auf die klassische Mechanik und Elektrodynamik aufgebaut ist, eine brauchbare Strahlungsformel liefern kann, sondern daß die klassische Theorie notwendig auf die Reileigh'sche Formel

$$\varrho = \frac{k\alpha}{h} \nu^2 T \tag{3}$$

führt. Als dann Planck in seiner grundlegenden Untersuchung seine Strahlungsformel

$$\varrho = \alpha \, \nu^3 \frac{1}{e^{\frac{h\nu}{kT}} - 1} \tag{4}$$

auf die Voraussetzung von diskreten Energie-Elementen gegründet hatte, aus welcher sich in rascher Folge die Quantentheorie entwickelte, geriet jene Wien'sche Überlegung, welche zur Gleichung (2) geführt hatte, naturgemäß wieder in Vergessenheit.

Vor kurzem nun fand ich eine der ursprünglichen Wien'schen Betrachtung¹) verwandte, auf die Grundvoraussetzung der Quanten-

Die räumliche Energieverteilung in der Hohlraumstrahlung.

Von **W. Bothe** in Charlottenburg.

(Eingegangen am 23. Oktober 1923.)

Einleitung. Die Hohlraumstrahlung ist ein statistisches Phänomen und muß als solches auch Schwankungserscheinungen aufweisen. Die theoretische Bedeutung der Energieschwankungen schätzt H. A. Lorentz 1) so hoch ein, daß er von ihnen den Schlüssel für die ganze Strahlungstheorie erwartet. Dies ist folgendermaßen zu verstehen: Ist die mittlere Energie E eines Systems als Funktion der Temperatur T bekannt, so liefert die statistische Mechanik ohne weiteres einen Ausdruck für das mittlere Quadrat der Energieschwankungen $\varDelta$ 2):

$$\overline{\varDelta^2} = kT^2 \frac{dE}{dT}, \tag{1}$$

wo k die Boltzmannsche Konstante ist. Auf die Plancksche Strahlungsformel

$$E = \frac{\alpha\nu^3}{e^{\frac{h\nu}{kT}} - 1} V \tag{2}$$

angewandt, lautet diese Gleichung:

$$\overline{\varDelta^2} = h\nu E + \frac{h}{\alpha\nu^2} \frac{E^2}{V}, \tag{3}$$

wenn V das betrachtete Strahlungsvolumen ist; die übrigen Bezeichnungen sind die üblichen 3). Jede Hypothese über die Struktur der Strahlung muß mit dieser Gleichung im Einklang sein. Nimmt man z. B. an, daß die Energie der Schwingungszahl ν in diskreten, voneinander unabhängigen Strahlungsquanten von der Größe $h\nu$ konzentriert ist, so findet man nach Analogie mit den Dichteschwankungen in einem idealen Gase:

$$\overline{\varDelta^2} = h\nu E.$$

Figure C.62: Walther Bothe further developed the theory of stimulated light emission from atoms (amplification of the number of photons of light from atoms) in 1923 [*Zeitschrift für Physik* (1923) 20:1:145–152].

Jost Lemmerich. 2011. *Science and Conscience: The Life of James Franck.* pp. 64–65.

[James Franck] pointed out furthermore that in electrical excitation of gases and vapors the series of spectrum lines are stimulated only very incompletely, since the higher terms of the series are weak in intensity. On the basis of his 1916 research with Hertz, Franck realized that this difficulty could be circumvented if a gas with a low excitation potential was added to one with a high excitation potential. Then very sharply defined lines of a sufficient intensity are easily obtained for the higher series of the gas of low excitation potential. Thus with an admixture of helium, hydrogen could be analyzed well. Such experiments became an important tool for verifying the different theories.

The next three papers brought Franck step by step closer to an experimental proof of a new behavior of electrons in the excited state inside an atom. Many decades later, these results would prove useful in the development of the laser.

[...] A footnote contained a premonition of the future discovery of the laser:

> [O]n the whole, the interesting fact that according to Paschen excited helium, that is, helium in an alkali-like state, exhibits a resonance emission, seems to us to offer a hint that the alkali-like state of helium is somewhat metastable. An electron raised out of this orbit into the next one always returns to this biquantum orbit and never jumps directly into the monoquantum stable orbit.

Franck was clearly on the way to discovering the metastable state of helium. The issue of the *Physikalische Zeitschrift* containing this paper appeared on November 1 [1919].

Heinrich Gerhard Kuhn. 1965. James Franck 1882–1964. *Biographical Memoirs of Fellows of the Royal Society* 11:52–74.
[https://royalsocietypublishing.org/doi/pdf/10.1098/rsbm.1965.0004]

Jointly with a number of co-workers Franck continued the study of the inelastic collisions of electrons with both atoms and molecules, of *excitation*- and *ionization-potentials*, but now with Bohr's theory as a guiding principle. The theoretical adviser of the group was Fritz Reiche, and it was Franck, Knipping and Reiche who coined the word '*metastable level*' and established the important part of metastable states in excitation processes. The question of how metastable atoms finally lose their energy, now strongly occupied Franck's attention.

Jost Lemmerich. 1987. *Zur Geschichte der Entwicklung des Lasers.* Berlin: DAVID. pp. 22–26, 59–60

In Berlin, an der Physikalisch-Technischen Reichsanstalt, war schon vor dem Ersten Weltkrieg Walther Bothe, der bei Planck promoviert hatte, für Hans Geiger als Mitarbeiter eingestellt worden. Bothe veröffentlichte 1923 als Fortführung der Arbeit Einsteins: "*Die räumliche Energieverteilung in der Hohlraumstrahlung*" <9>. In der Einleitung faßte er noch einmal die Ergebnisse von Einsteins Veröffentlichungen zusammen und benutzt dabei die Nomenklatur *spontane Emission* für den üblichen Vorgang der Ausstrahlung bei der Anregung von Atomen, *Absorption* bzw. *positive Einstrahlung* und *erzwungene Emission* bzw. *negative Einstrahlung.* Wörtlich heißt es dann bei der Interpretation von Einsteins Ergebnissen:

"*Weiterhin schließt Einstein durch Impulsbetrachtungen, daß ein ungestörtes thermodynamisches Gleichgewicht zwischen der Strahlung und der Wärmebewegung eines Gases nur möglich ist, wenn die drei angegebenen Elementarprozesse streng gerichtet verlaufen, d.h. absorbiert eine Molekul Strahlung, so entnimmt sie diese einem Strahlenbündel von unendlich kleiner Konvergenz; entsprechend wird bei der Emission die Energie in einem unendlich kleinen Raumwinkel gestrahlt, sie breitet sich nicht seitlich aus; im Falle der erzwungenen Emission ist die Emissionsrichtung genau die desjenigen einfallenden Strahlenbündels, welches die Emission verursacht, während die Richtung der spontane Emission dem Zufall unterliegt.*"

Wiederum war damit deutlich ausgesprochen, daß die erzwungene, stimulierte Emission zu einer Lichtquelle in einem kleinen Raumwinkel führen müßte. Die Frage der Kohärenz wird—wie auch bei Einsteins Arbeit—durch Bothe nicht angesprochen.

In Berlin, at the Physikalisch-Technische Reichsanstalt, Walther Bothe, who had completed his doctorate under Planck, had already been employed by Hans Geiger before the First World War. Bothe published in 1923 as a continuation of Einstein's work: "*The spatial energy distribution in cavity radiation*" <9>. In the introduction he once again summarized the results of Einstein's publications and used the nomenclature *spontaneous emission* for the usual process of radiation from the excitation of atoms, *absorption* or *positive irradiation* and *stimulated emission* or *negative irradiation.* The interpretation of Einstein's results literally means:

"*In addition, Einstein concludes by impulse considerations that an undisturbed thermodynamic equilibrium between the radiation and the thermal motion of a gas is only possible if the three specified elementary processes are strictly directional, i.e. if a molecule absorbs radiation, it takes it from a beam of infinitely small convergence; accordingly, during emission, the energy is radiated in an infinitely small solid angle, it does not propagate laterally; in the case of stimulated emission, the direction of emission is exactly that of the incident beam causing the emission, while the direction of spontaneous emission is random.*"

Again it was clearly stated that the forced, stimulated emission must lead to a light source within a small solid angle. The question of coherence is not addressed by Bothe—as also in Einstein's work.

Der Hauptteil der Botheschen Arbeit behandelt den Vorgang des Auftretens von Quantenpaaren, also doppelten und mehrfachen davon, bei der erzwungenen Emission. Bothe gibt auch eine Methode zum Nachweis der Quantenpaare an.

Nur ein Jahr nach Bothes Arbeit erschien das *Physikalische Handwörterbuch* <10>, herausgegeben von Arnold Berliner und Karl Scheel. Für das Stichwort Lichtquanten referiert A. Smekal. Während Smekal die Lichtquantenhypothese Einsteins für die Wechselwirkung zwischen Strahlung und Materie anerkennt, fährt er fort:

"*Einsteins Betrachtungen über das Impulsgleichgewicht zwischen Materie und Strahlung (s. Nadelstrahlung) beweisen zwar, daß die Strahlungsemission nicht in Kugelwellen—wie nach der klassischen Elektrodynamik—, sondern im gewissen Sinne einseitig, also gerichtet, erfolgt, was zweifellos nicht zu ungunsten der Lichtquanten spricht, doch lassen sich bindende Schlüsse auf die Eigenschaft freier Lichtquanten hieraus ebenfalls nicht ziehen. Eine endgültige Beurteilung der Lichtquantenhypothese, die übrigens zu gewissen Schwierigkeiten mit dem Kausalitätsprinzip zu führen scheint, ist daher bis jetzt noch nicht möglich gewesen.*"

Seit 1900 hatte die Experimentalphysik große Fortschritte gemacht. Für die technische Durchgestaltung der Glühlampe war es notwendig gewesen, bessere Vakuumpumpen zu entwicklen. Ebenso erforderte die Herstellung von Verstärkerröhren einfach zu handhabende Hochvakuumpumpen. Diese technischen Möglichkeiten der Vakuumerzeugung nutzen die Physiker, um ihrerseits intensiv die Erforschung der Physik der Gasentladungen aufzugreifen.

The main part of Bothe's work deals with the process of the occurrence of quantum pairs, i.e. double and multiple quantum pairs, in stimulated emission. Bothe also gives a method for the detection of quantum pairs.

Only one year after Bothe's work the *Dictionary of Physics* <10>, edited by Arnold Berliner and Karl Scheel, appeared. A. Smekal writes the entry on light quanta. While Smekal acknowledges Einstein's light quantum hypothesis for the interaction between radiation and matter, he continues:

"*Einstein's considerations about the impulse equilibrium between matter and radiation (see directional radiation) prove indeed that the radiation emission does not take place in spherical waves—like according to the classical electrodynamics—, but is in a certain sense one-sided, thus directed, which undoubtedly does not speak to the disadvantage of the light quanta, but binding conclusions about the property of free light quanta cannot be drawn from this either. A final evaluation of the light quantum hypothesis, which by the way seems to lead to certain difficulties with the causality principle, has therefore not yet been possible.*"

Since 1900 experimental physics had made great progress. For the technical design of the incandescent lamp it had been necessary to develop better vacuum pumps. The manufacture of amplifier tubes also required high-vacuum pumps that were easy to handle. The physicists used these technical possibilities of vacuum generation to intensively investigate the physics of gas discharges.

Am Kaiser-Wilhelm-Institut für Physikalische Chemie in Berlin untersucht Fritz Reiche und Paul Knipping unter Leitung von James Franck die Wechselwirkung von Elektronen mit Atomen. Regt man Atome mit Elektronen an, wie dies James Franck und Gustav Hertz in ihrem klassischen Experiment 1913 getan hatten, so kann mann nicht nur die Energieniveaus der Elektronen im Atom bestimmen, sondern konnte damals bereits erste Angaben über die Lebensdauer der angeregten Zustände machen. In der Veröffentlichung von 1920 in der Zeitschrift für Physik beschreiben Franck und Reiche die Ergebnisse ihrer Messungen an Helium <11>. Die übliche Verweilzeit von Elektronen im angeregten Zustand beträgt nur etwa 10^{-8} Sekunden. Franck und Reiche konnten zeigen, daß im angeregten Helium ein Zustand existierte, der wesentlich langlebiger ist, den sie metastabilen Zustand nannten. Dieser metastabile Zustand hat ein etwas niedrigeres Energieniveau als der sehr viel kurzlebigere.

Nachdem James Franck einen Ruf an die Universität Göttingen annahm, führte er dort mit seinen Mitarbeitern die Untersuchungen weiter und fand, daß es bei Gasgemischen möglich ist, über die Anregung eines Bestandteiles der andern Bestandteil anzuregen. Dies geschieht durch die Übertragung der Anregungsenergie, ohne daß es dabei zur Aussendung von Strahlung kommt. Man bezeichnet dies als Stöße zweiter Art <12>.

Nach dem Fortgang von Franck nach Göttingen trat Rudolf Ladenburg in das Kaiser-Wilhelm-Institut für Physikalische Chemie ein und Ende der 20er Jahre erschien in rascher Folge eine Reihe von Arbeiten über die Untersuchung der anomalen Dispersion bei Gasentladungen <13>.

At the Kaiser Wilhelm Institute for Physical Chemistry in Berlin, Fritz Reiche and Paul Knipping, led by James Franck, are investigating the interaction of electrons with atoms. If one excites atoms with electrons, as James Franck and Gustav Hertz had done in their classical experiment of 1913, then one can not only determine the energy levels of the electrons in the atom, but could also make initial statements about the lifetime of the excited states at that time. In the publication of 1920 in the Zeitschrift für Physik Franck and Reiche describe the results of their measurements of helium <11>. The usual residence time of electrons in the excited state is only about 10^{-8} seconds. Franck and Reiche were able to show that in excited helium a state existed which is much more long-lived, which they called a metastable state. This metastable state has a slightly lower energy level than the much shorter one.

After James Franck accepted a call to the University of Göttingen, he and his colleagues continued the investigations and found that in gas mixtures it is possible to stimulate one component by stimulating the other component. This is done by transferring the excitation energy without emitting radiation. This is called second type shock <12>.

After Franck had left for Göttingen, Rudolf Ladenburg joined the Kaiser Wilhelm Institute for Physical Chemistry and at the end of the 1920s a series of papers on the investigation of the anomalous dispersion in gas discharges <13> appeared in rapid succession.

Ladenburg arbeitete mit verschiedenen Mitarbeitern zusammen, u.a. mit Hans Kopfermann. Das Ziel ihrer Versuche war die Untersuchung des Gleichgewichtes zwischen den Elektronen und angeregten Atomen. Dazu führten sie spektroskopische Messungen an Gasentladungen durch, die in verhältnismäßig dünnen und langen Röhren—ähnlich den späteren Laser-Röhren—brannten. Durch die angewendeten Anregungsbedingungen erreichten sie eine sogenannte Inversion der Besetzungszustände im Neon. Das heißt, in einem angeregten Energieniveau befanden sich mehr Elektronen als im Grundzustand. Eine Grundbedingung, um einen Laser zu betreiben.

Zusammenfassend referierte Ladenburg über diese Arbeiten nach seiner Übersiedlung nach Amerika vor 1933 in der Zeitschrift Reviews of Modern Physics unter dem Titel “*Dispersion in electrically excited gases*” <14>.

Franck und Ladenburg waren mit Einstein, der immer an experimentellen Arbeiten interessiert war, gut befreundet. Es ist verwunderlich, daß sie offenbar niemals über diese Arbeiten im Zusammenhang mit seinem Ideen über die erzwungene Emission diskutierten, zumal Ladenburg bei seinem Arbeiten zusammen mit Levy zur Untersuchung der Struktur den Linien seiner Gasentladungen ein Fabry-Perot-Inteferometer <15> anwendete. Dieses Interferometer besteht aus zwei senkrecht in einem festen Abstand zueinander stehenden Spiegeln. Es stellt einer Art optischen Hohlraumresonator dar und kann als Rückkopplung der Strahlung in den dazwischenliegenden Hohlraum betrachtet werden. (Die damals verwendeten Spiegel mit versilberten Oberflächen hätten allerdings nicht die Möglichkeit zugelassen, mit einer Gasentladung einen Laser in Gang zu setzen, da die Reflexion zu niedrig war.)

Ladenburg worked with various collaborators, including Hans Kopfermann. The aim of their experiments was to investigate the equilibrium between electrons and excited atoms. For this purpose they carried out spectroscopic measurements on gas discharges, which glowed in relatively thin and long tubes, similar to the later laser tubes. Through the applied excitation conditions they achieved a so-called inversion of the occupation states in the neon. This means that in an excited energy level there were more electrons than in the ground state. A basic condition for operating a laser.

As a summary, Ladenburg spoke about these works after his move to America before 1933 in the journal Reviews of Modern Physics under the title “*Dispersion in electrically excited gases*” <14>.

Franck and Ladenburg were good friends with Einstein, who was always interested in experimental work. It is surprising that they apparently never discussed this work in connection with his ideas about stimulated emission, especially since Ladenburg and Levy used a Fabry-Perot inteferometer <15> to investigate the structure of the gas discharge lines. This interferometer consists of two perpendicular mirrors at a fixed distance from each other. It is a kind of optical cavity resonator and can be considered as feedback of the radiation into the intermediate cavity. (The mirrors with silver-plated surfaces used at that time, however, would not have allowed the possibility of starting a laser with a gas discharge, since the reflection was too low.)

[Lemmerich’s claim that German mirrors circa 1930 were not good enough to make a laser is false. Companies such as Zeiss and Leitz had been making extremely high-quality optical components, including mirrors, since the mid-1800s. Moreover, it is actually preferable for one or both mirrors of a laser not to be perfectly reflecting, so that some of the light can escape to form a beam.]

Im Oktober 1932 schloß Max Born das Manuskript für sein Buch "*Optik—ein Lehrbuch der elektromagnetischen Lichttheorie*" <16> ab. Es wurde einer Generation von Physikern, die sich mit der Theorie der Optik beschäftigten, das wichtigste Lehrbuch. Als die Radartechnik während des Zweiten Weltkrieges entwickelt wurde, griff man auf Borns grundlegendes Buch zurück, denn eine Verbindung von Hochfrequenztechnik und Optik bahnte sich an.

Born ging in seinem Buch ausführlich auf die Erscheinungen der Interferenz und Kohärenz sowie der stehenden Wellen ein, die bereits Wiener 1899 beim Licht nachgewiesen hatte. Detailiert beschrieb er auch die Interferometer, wie das von Fabry-Perot. Als theoretischer Physiker widmete er besondere Sorgfalt den theoretischen Betrachtungen über das Verständnis der Emission, Dispersion und anomalen Dispersion. Born referierte sowohl Einsteins wie auch Ladenburgs Arbeiten. Jedoch wurden Begriffe wie Rückkopplung und phasengerechte Verstärkung im Zusammenhang mit Emissionsvorgängen nicht diskutiert.

In October 1932, Max Born completed the manuscript for his book "*Optics–a Textbook of Electromagnetic Light Theory*" <16>. It became the most important textbook for a generation of physicists working in the theory of optics. When radar technology was developed during the Second World War, Born's basic book was used because a combination of high frequency technology and optics was emerging.

In his book Born dealt in detail with the phenomena of interference and coherence as well as standing waves, which had already been demonstrated by Wiener in 1899. He also described the interferometers in detail, such as that of Fabry-Perot. As a theoretical physicist he devoted special attention to theoretical considerations about the understanding of emission, dispersion and anomalous dispersion. Born lectured on both Einstein's and Ladenburg's work. However, terms such as feedback and phase-adjusted gain were not discussed in connection with emission processes.

Ein Ansatz zum Bau einer intensiven monochromatischen kohärenten Lichtquelle für Untersuchungen in der Optik zeigte sich nicht. Beim Experimentieren mußte man sich mit vorgeschalteten Filtern und einer Lochblende begnügen, um eine kohärente Lichtquelle aus dem Licht einer Glühlampe zu realisieren. Die Intensität war infolge der verwendeten Lochblende meist nur sehr gering und führte zu langen Belichtungszeiten. Ein wenig besser waren gekühlte Spektrallampen; vor allen Dingen die Lampen mit Thallium-Füllung wurden für interferometrische Untersuchungen verwendet. Die Entwicklung von Niederdruckspektrallampen war durch viele Physiker gefördert worden, so auch durch den ungarischen Physiker Dennis Gábor <17>, als er Mitarbeiter der Firma Siemens war. Nach seiner Emigration war er auf vielen Gebieten der angewandten Physik tätig. Ihm gelang 1948 eine aufsehenserregende Erfindung, die Abspeicherung eines dreidimensionalen Bildes auf der zweidimensionalen Photoplatte, die Holographie. Für die Aufnahme benötigte man monochromatische Lichtquelle großer Kohärenzlänge. Aber es gab sie damals noch nicht, und so ging die Entwicklung der Holographie nur langsam voran, denn man konnte nur kleine Objekte aufnehmen. Offenbar hat auch Gábor selbst dieses Problem der Lichtquelle nicht zu lösen versucht <18>.

11. Franck, James u. Reiche, Fritz: Zeitschrift für Physik, **1** (1920), S. 154.

An approach for the construction of an intense monochromatic coherent light source for investigations in optics was not found. When experimenting, one had to be content with filters and a pinhole diaphragm in order to realize a coherent light source from the light of an incandescent lamp. Due to the pinhole aperture used, the intensity was usually very low and led to long exposure times. Cooled spectral lamps were a little better; especially thallium-filled lamps were used for interferometric investigations. The development of low-pressure spectral lamps had been supported by many physicists, including the Hungarian physicist Dennis Gábor <17> when he worked for Siemens. After his emigration he worked in many fields of applied physics. In 1948 he succeeded in a sensational invention, the storage of a three-dimensional image on a two-dimensional photo plate, holography. Monochromatic light sources of long coherence length were required for the recording. But they did not exist at that time, and so the development of holography progressed only slowly, because only small objects could be recorded. Apparently Gábor himself did not try to solve this problem of the light source <18>.

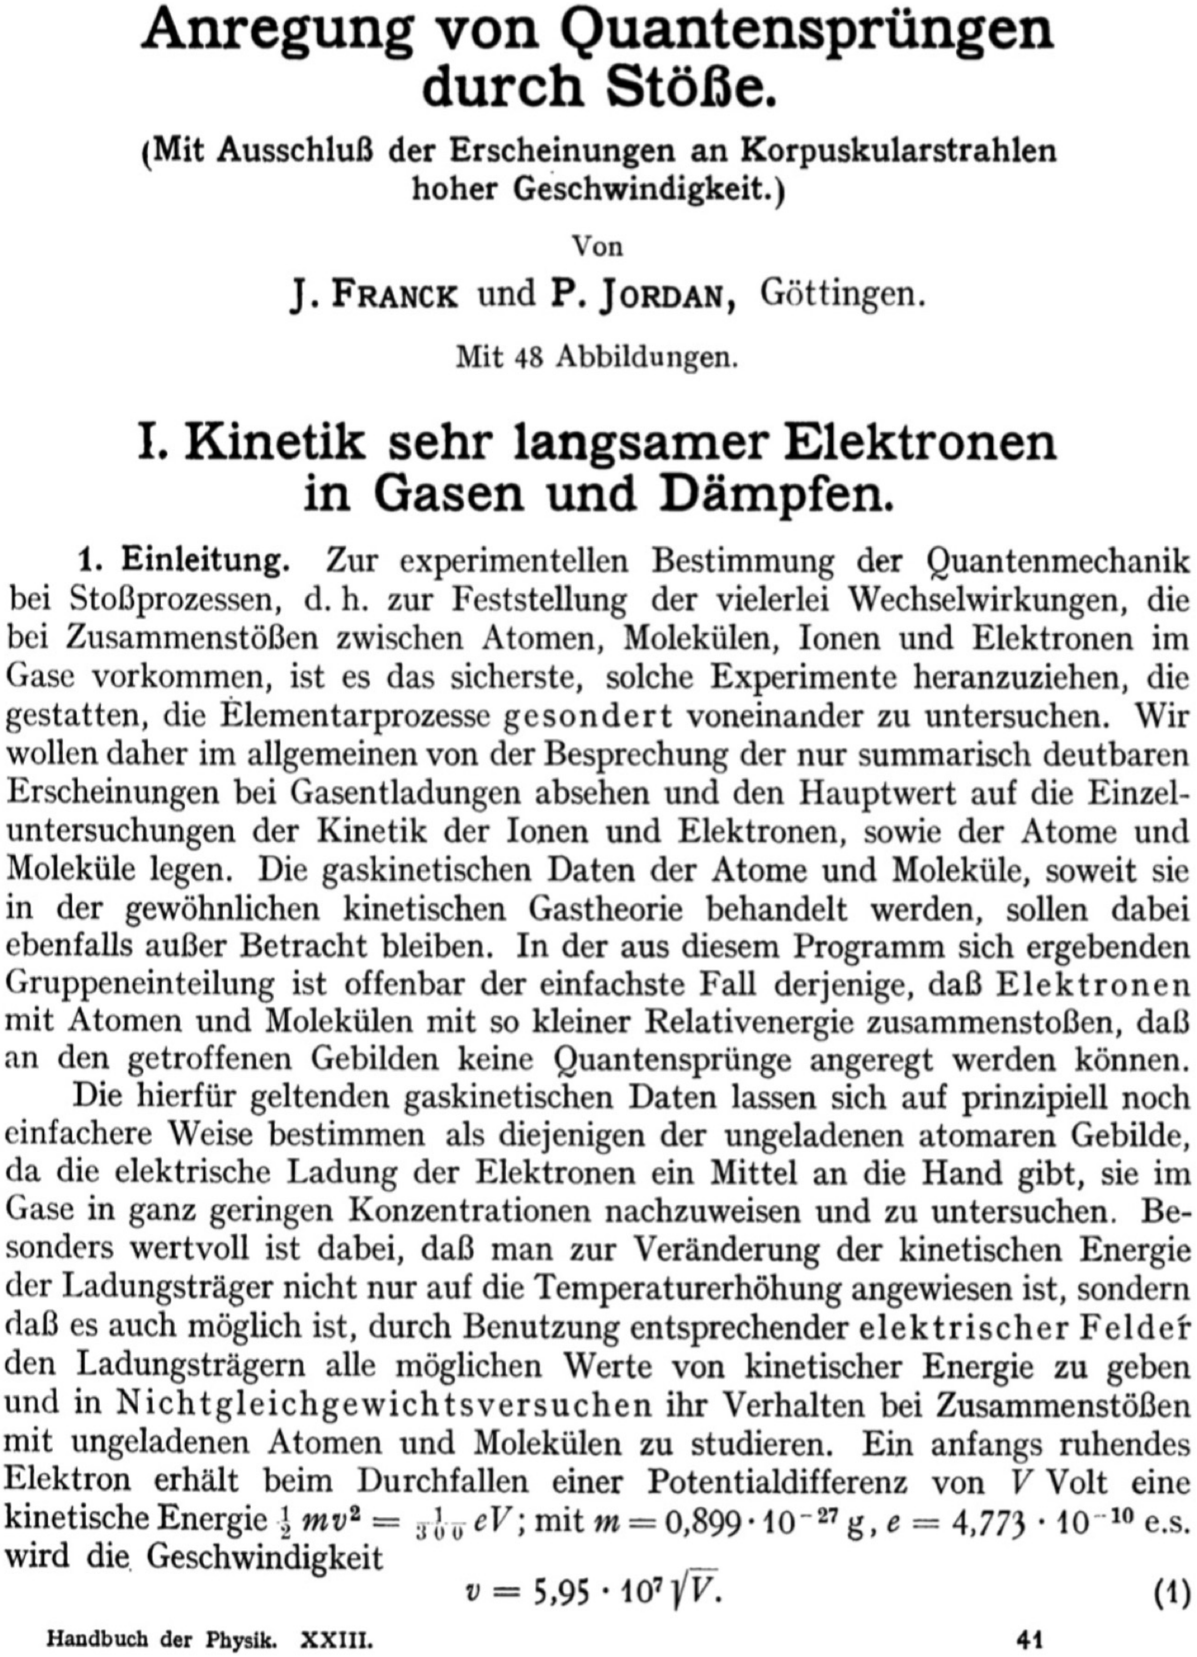
17. Gábor, Dennis (formerly Dénes) has registered two inventions about metal arc lamps within the scope of his activity in the research laboratory of Siemens & Halske AG in 1930. In 1933 he was granted the DRP 570606 and 570608.

18. Gábor wrote on 28.5.1963 from London to Max Born about Born's essay "The Scientist Speculates" and about his thoughts about building a laser in 1950. He addresses the problem of the responsibility to publish ideas. This problem became particularly apparent later in the development of the laser, when speculative ideas were repeatedly published without any attempt at realization and the question of priority for the successful experiment was discussed.
The letter is in the estate of Born, Manuscript Department, Staatsbibliothek Preußischer Kulturbesitz, Berlin.



Anregung von Quantensprüngen durch Stöße.

(Mit Ausschluß der Erscheinungen an Korpuskularstrahlen hoher Geschwindigkeit.)

Von

J. Franck und **P. Jordan**, Göttingen.

Mit 48 Abbildungen.

I. Kinetik sehr langsamer Elektronen in Gasen und Dämpfen.

1. Einleitung. Zur experimentellen Bestimmung der Quantenmechanik bei Stoßprozessen, d. h. zur Feststellung der vielerlei Wechselwirkungen, die bei Zusammenstößen zwischen Atomen, Molekülen, Ionen und Elektronen im Gase vorkommen, ist es das sicherste, solche Experimente heranzuziehen, die gestatten, die Elementarprozesse gesondert voneinander zu untersuchen. Wir wollen daher im allgemeinen von der Besprechung der nur summarisch deutbaren Erscheinungen bei Gasentladungen absehen und den Hauptwert auf die Einzeluntersuchungen der Kinetik der Ionen und Elektronen, sowie der Atome und Moleküle legen. Die gaskinetischen Daten der Atome und Moleküle, soweit sie in der gewöhnlichen kinetischen Gastheorie behandelt werden, sollen dabei ebenfalls außer Betracht bleiben. In der aus diesem Programm sich ergebenden Gruppeneinteilung ist offenbar der einfachste Fall derjenige, daß Elektronen mit Atomen und Molekülen mit so kleiner Relativenergie zusammenstoßen, daß an den getroffenen Gebilden keine Quantensprünge angeregt werden können.

Die hierfür geltenden gaskinetischen Daten lassen sich auf prinzipiell noch einfachere Weise bestimmen als diejenigen der ungeladenen atomaren Gebilde, da die elektrische Ladung der Elektronen ein Mittel an die Hand gibt, sie im Gase in ganz geringen Konzentrationen nachzuweisen und zu untersuchen. Besonders wertvoll ist dabei, daß man zur Veränderung der kinetischen Energie der Ladungsträger nicht nur auf die Temperaturerhöhung angewiesen ist, sondern daß es auch möglich ist, durch Benutzung entsprechender elektrischer Felder den Ladungsträgern alle möglichen Werte von kinetischer Energie zu geben und in Nichtgleichgewichtsversuchen ihr Verhalten bei Zusammenstößen mit ungeladenen Atomen und Molekülen zu studieren. Ein anfangs ruhendes Elektron erhält beim Durchfallen einer Potentialdifferenz von V Volt eine kinetische Energie $\frac{1}{2} mv^2 = \frac{1}{300} eV$; mit $m = 0{,}899 \cdot 10^{-27}$ g, $e = 4{,}773 \cdot 10^{-10}$ e.s. wird die Geschwindigkeit

$$v = 5{,}95 \cdot 10^7 \sqrt{V}. \qquad (1)$$

Handbuch der Physik. XXIII. 41

Figure C.63: James Franck collaborated with many other scientists such as Pascual Jordan to conduct theoretical and experimental analyses of light emission from atoms (including aspects of stimulated emission) during the late 1910s and the 1920s [*Handbuch der Physik* (1926) 23:641–775].

Hendrik A. Kramers. 1925. *Skand. Mat. Kongr.* p. 145 [quoted in Bertolotti 2015, pp. 20–21].

If the atom is in one of its higher states, also terms belonging to the second sum inside the brackets of [equation] will appear. In the neighborhood of the frequency ν_{em} of an emission line, the atom will then give rise to an anomalous dispersion of similar kind as in the case of an absorption line, with the difference that the sign of P is reversed. This so-called *negative dispersion* is closely connected with the prediction made by Einstein that the atom for such a frequency will exhibit a *negative absorption*, that is, light waves of this frequency, passing through a great number of atoms in the state under consideration, will increase in intensity.

[In 1920–1921, Christian Füchtbauer (German, 1877–1959) and Rudolf Ladenburg (German, 1882–1952) wrote the first papers using newly developed quantum physics methods to calculate normal or positive absorption of light, as well as negative absorption or light amplification due to stimulated emission of photons in a material composed of excited atoms:

> Christian Füchtbauer. 1920. Die Absorption in Spektrallinien im Lichte der Quantentheorie. *Physikalische Zeitschrift* 21:322–324.
>
> Rudolf Ladenburg. 1921. Die quantentheoretische Deutung der Zahl der Dispersionselektronen. *Zeitschrift für Physik* 4:451–468.

Their theoretical result is now known as the Füchtbauer–Ladenburg equation for calculating the optical gain or light amplification of a laser material containing excited atoms.

Based on those theoretical predictions, Rudolf Ladenburg and other members of his group at the Kaiser Wilhelm Institut für Physikalische und Elektrochemie (such as Hans Kopfermann, Agathe Carst, S. Levy, and Günther Wolfsohn) conducted experiments from the 1920s until 1931 that conclusively demonstrated the existence of stimulated emission and optical amplification in electrically excited gases. Examples of some of the resulting papers are shown on pp. 3116–3127.

However, rising antisemitism in Germany drove Ladenburg to the United States, where he accepted a position in 1931. In 1933, Ladenburg published one last paper on the topic from the United States, basically summarizing the research he had conducted in Germany. It appears that he was unable to interest U.S. sponsors in funding him to continue his revolutionary research program.

If Ladenburg had been allowed to continue leading his research group at the Kaiser Wilhelm Institut, his group might have produced the first laser as early as the 1930s. Even so, his numerous, highly detailed, and highly visible publications on stimulated emission in electrically excited gases had an enormous influence on later work in the German-speaking world, the United States, and elsewhere.]

Rudolf Ladenburg. 1933. Dispersion in Electrically Excited Gases. *Reviews of Modern Physics* 5:243.

All these different experiments prove without doubt that the population of the P levels does increase with the current, and so much so that above 100 mA, the ratio Q $(= N_k g_j / N_j g_k)$ has appreciable value. Therefore the experiments shown by the curves [...] prove the influence of the negative term in the dispersion formula. This "negative dispersion" corresponds to the negative absorption of the theory of radiation and to the term -1 in the denominator of Planck's formula for the radiation of a black body as is easily shown by Einstein's derivation of this formula.

Untersuchungen über die anomale Dispersion angeregter Gase*.

I. Teil.

Zur Prüfung der quantentheoretischen Dispersionsformel.

Von **Rudolf Ladenburg** in Berlin-Dahlem.

Mit 2 Abbildungen. (Eingegangen am 17. Dezember 1927.)

Die quantentheoretische Dispersionsformel für den Brechungsquotienten eines verdünnten Gases nahe einer isolierten Spektrallinie, aber außerhalb des eigentlichen Absorptionsgebietes lautet

$$n-1=\frac{e^2}{4\pi c^2 m}\frac{\lambda_{kj}^3}{\lambda-\lambda_{kj}}N_j f_{kj}\left(1-\frac{N_k}{N_j}\frac{g_j}{g_k}\right),$$

wobei die „Oszillatorenstärke"

$$f_{kj}=A_{kj}\frac{g_k}{g_j}\frac{m c^3}{8\pi^2 e^2 \nu_{kj}^2}$$

ist. Daher entspricht die in der klassischen Dispersionsformel auftretende „Zahl der Dispersionselektronen" $\mathfrak{N}$ dem Ausdruck

$$N_j f_{kj}\left(1-\frac{N_k}{N_j}\frac{g_j}{g_k}\right).$$

Der Klammerausdruck enthält den Einfluß der „negativen" Dispersion, N_j und N_k sind die Atomdichten in den Zuständen j und k, g_j und g_k die zugehörigen statistischen Gewichte. A_{kj} ist die Einsteinsche Übergangswahrscheinlichkeit. Es wird auf Grund vorliegender Versuche gezeigt, daß sich die angegebene Beziehung zwischen f und A im Fall der D-Linien des Na exakt bestätigt. Ferner wird an Hand der Dispersionsformel dargelegt, wie man mittels Messung anomaler Dispersion Übergangswahrscheinlichkeiten und Dichte angeregter Atome bestimmen, und unter welchen Umständen man eventuell den Einfluß der negativen Dispersion nachweisen kann.

1. Die erste erfolgreiche Behandlung der Dispersionserscheinungen auf Grund der Bohrschen Atomtheorie** enthielt implizite die Voraussetzung, daß die Umlaufsfrequenzen der Bohrschen Elektronen die ausgezeichneten Stellen seien, an denen die Dispersion ihr Vorzeichen wechselt***.

Untersuchungen über die anomale Dispersion angeregter Gase.

II. Teil*.

Anomale Dispersion in angeregtem Neon.

(Einfluß von Strom und Druck, Bildung und Vernichtung angeregter Atome.)

Von **Hans Kopfermann** und **Rudolf Ladenburg** in Berlin-Dahlem.

Mit 6 Abbildungen. (Eingegangen am 17. Dezember 1927.)

1. Versuchsanordnung. 2. Meßmethoden, Genauigkeit. 3. Kontrollversuche. 4. Abhängigkeit der a. D. vom Strom. 5. Theoretische Deutung. 6. Abhängigkeit der a. D. vom Druck und ihre Deutung. 7. Zusammenfassung. — In der positiven Säule des mit Gleichstrom betriebenen Neonrohrs wird an den etwa 20 im Rotgelb gelegenen $s_5 - p_k$-, $s_4 - p_k$-, $s_3 - p_k$-Linien anomale Dispersion (a. D.) in ihrer Abhängigkeit von Strom und Druck gemessen. Mit wachsendem Strom steigt die a. D., d. h. die Zahl der N_{s_i}-Atome in den s_5-, s_4- und s_3-Zuständen, mehr oder weniger rasch an, nähert sich aber bald einem Sättigungswert, der bei 50 mA bereits annähernd erreicht ist. Dies wird durch die Bildung und Vernichtung der s_i-Atome durch Elektronenstoß gedeutet. Die Beobachtungen an den metastabilen s_5- und s_3-Atomen, und in Annäherung auch an den instabilen s_4-Atomen sind darstellbar durch die Gleichgewichtsformel:

$$N_s = \frac{a\,J}{b\,J + c},$$

wo J Stromstärke, a bzw. b und c stromunabhängige Erzeugungs- bzw. Vernichtungsfaktoren sind. Sättigung tritt ein, wenn $b\,J \gg c$, dann ist $\overline{N}_s = a/b =$ const. Zum Verständnis der Beobachtungen an den s_4-Atomen ist ihre Nachfüllung aus den s_5- und s_3-Atomen und durch die starke Reabsorption der Linie $p_0 - s_4$ (743 Å) zu berücksichtigen, die die mittlere Lebensdauer der instabilen s_4-Atome wesentlich vergrößert. Druckeinfluß: 1. Mit wachsendem Druck nehmen oberhalb 1,3 mm die Sättigungswerte $\overline{N}_s$ ab; 2. gleichzeitig tritt die Sättigung bei immer kleineren Stromwerten ein. Ursache: Bei gleichem Strom und wachsendem Druck bleibt der Anteil der mittelschnellen anregenden Elektronen im wesentlichen konstant oder nimmt ab; dagegen nimmt gleichzeitig der Anteil der langsamen Elektronen, die die Vernichtung der angeregten Atome durch Stoß bewirken, aus verschiedenen Gründen zu. Daher wächst in der Gleichgewichtsformel b mit dem Druck schneller als a und wesentlich schneller als c, und es nimmt mit wachsendem Druck 1. $\overline{N}_s$ ab, und 2. auch der Strom J, bei dem $b\,J \gg c$ ist und Sättigung eintritt.

1. Versuchsanordnung. Die Versuchsanordnung ist im wesentlichen dieselbe, die bereits von dem einen von uns zur Untersuchung

Untersuchungen über die anomale Dispersion angeregter Gase.

III. Teil*.

Übergangswahrscheinlichkeit und Dichte angeregter Atome im Neon; statistisches Gleichgewicht in der positiven Säule.

Von **Hans Kopfermann** und **Rudolf Ladenburg** in Berlin-Dahlem.

(Eingegangen am 17. Dezember 1927.)

1. Aus den in U. a. D. II. mitgeteilten Messungen der anomalen Dispersion (a. D.) an den gelbroten Neonlinien in der positiven Säule werden die relativen Oszillatorenstärken f_{kj} und Übergangswahrscheinlichkeiten A_{kj} der zum gleichen unteren Zustand j gehörigen Linien berechnet. Diese Relativwerte sind bemerkenswerterweise unabhängig von Strom und Druck (Tabelle 6 und 7). — 2a. Durch Verwertung der relativen Intensitätsmessungen Dorgelos und geeignete Kombination mit unseren Messungen der a. D. werden nach U. a. D. I., 6 die relativen Atomdichten in den Zuständen s_5, s_4 und s_3 berechnet. Das Verhältnis $Ns_5 : Ns_4 : Ns_3$ nähert sich mit wachsendem Strom (unabhängig vom Druck) dem Werte 100 : 60 : 20 des statistischen Gleichgewichts bei sehr hoher Temperatur. Mit Benutzung dieses Wertes werden die A-Werte sämtlicher Linien, bezogen auf die Linie 6402, berechnet. — 2b. Dasselbe Ergebnis folgt auch mit Benutzung des f-Summensatzes (ohne Verwertung der Intensitätsmessungen). Zugleich werden so die Absolutwerte der Oszillatorenstärken, der Übergangswahrscheinlichkeiten, der Lebensdauern und der Atomdichten der angeregten s-Zustände abgeschätzt.

1. Die Relativwerte der Übergangswahrscheinlichkeiten. Im vorangehenden Teil II der U. a. D. haben wir die Methode zur genauen Messung der anomalen Dispersion (a. D.) an den im Rotgelb gelegenen Linien $s_j - p_k$ des Neons dargelegt sowie die Berechnung der die Größe der a. D. kennzeichnenden $\mathfrak{N}$-Werte [s. Teil I, 2, Gleichung (3)] und ihre Abhängigkeit von Strom und Druck mitgeteilt. Dabei wurde der Strom von 0,5 bis etwa 100 mA und der Druck zwischen 1 und 9 mm variiert. Besonders bemerkenswert sind dabei die Sättigungswerte $\overline{\mathfrak{N}}$, denen sich die $\mathfrak{N}$-Werte der einzelnen Linien mit wachsendem Strom nähern; bei den leicht erreichbaren Stromstärken von 50 mA sind die gemessenen $\mathfrak{N}$-Werte von den Endwerten $\overline{\mathfrak{N}}$ anscheinend nur noch wenig

Untersuchungen über die anomale Dispersion angeregter Gase*.

IV. Teil.

Anomale Dispersion des Wasserstoffs; wahres Intensitätsverhältnis der Wasserstofflinien H_α und H_β.

Von **Agathe Carst** und **Rudolf Ladenburg** in Berlin-Dahlem.

Mit 1 Abbildung. (Eingegangen am 2. Januar 1928.)

Durch starke Anregung von atomarem Wasserstoff mit Gleichstrom von 0,2 bis 1 Amp./qcm wird anomale Dispersion an H_α und H_β erzeugt und photographisch gemessen. Für das Verhältnis der „Zahl der Dispersionselektronen“ $\mathfrak{N}_\alpha/\mathfrak{N}_\beta$ ergibt sich 4,7. Dies Verhältnis ist nach der quantentheoretischen Dispersionsformel in erster Annäherung gleich dem der „Stärke“ f_α/f_β der entsprechenden Quantenübergänge bzw. im wesentlichen gleich dem der Übergangswahrscheinlichkeiten. Hierfür berechnet man nach der Quantenmechanik den Wert 5,37. Der Unterschied gegen den gemessenen Wert liegt etwas außerhalb der Meßfehler, er kann durch den Einfluß negativer Dispersion gedeutet werden, denn diese darf bei der starken Anregung des Wasserstoffs wahrscheinlich nicht unberücksichtigt bleiben, wie bei der Proportionalität von $\mathfrak{N}$ und f in erster Annäherung angenommen wird.

1. Ziel der Untersuchung.

Die anomale Dispersion (a. D.) des leuchtenden Wasserstoffs, speziell an den Linien H_α und H_β, wurde zwar schon früher von dem einen von uns, z. T. gemeinsam mit St. Loria, untersucht**, jedoch dienten damals Kondensatorentladungen (elektrische Schwingungen starker Dämpfung) zur Erregung des Wasserstoffs, so daß als Lichtquelle eine vom gleichen Schwingungskreis erregte Wasserstoffkapillare benutzt werden mußte. Diese gab in der Tat in der Umgebung der Balmerlinien ein genügend ausgedehntes kontinuierliches Spektrum, erschwerte aber quantitative Untersuchungen erheblich. Inzwischen ist es R. W. Wood*** gelungen, die Bedingungen zur Erzeugung von hochkonzentriertem atomaren Wasserstoff aufzufinden;

Untersuchungen über die anomale Dispersion angeregter Gase.

V. Teil*.

Negative Dispersion in angeregtem Neon**.

Von **H. Kopfermann** und **R. Ladenburg** in Berlin-Dahlem.

Mit 6 Abbildungen. (Eingegangen am 12. August 1930.)

Bei Steigerung der Stromdichte in der positiven Säule einer Neon-Entladung findet man zunächst ein Ansteigen der anomalen Dispersion an den rotgelben s-p-Linien, gemessen durch die Werte $\mathfrak{N}$, und zwar verhalten sich alle zum gleichen unteren s-Zustand gehörigen Linien in gleicher Weise — dies entspricht dem Ansteigen der Atomdichten im s-Zustand N_s. Vermehrt man aber die Stromdichte über $\sim 0{,}1$ Amp./qcm (bei 1 mm Neondruck), so nehmen die $\mathfrak{N}$-Werte wieder langsam ab, und zwar für die verschiedenen Linien $s_5 - p_{10}$, p_9, p_8 . . . bis p_2 in merklich verschiedener Weise (Fig. 4 und 5). Dies ist durch das allmähliche und verschieden starke Anwachsen der Atomdichten in den p-Zuständen, $N_{p_{10}}$, N_{p_9} . . . zu deuten und durch die dadurch hervorgerufene „negative Dispersion“ gemäß der Formel

$$\mathfrak{N}_{s_5 p_k} = N_{s_5} f_{s_5 p_k}\left(1 - \frac{N_{p_k}}{N_{s_5}} \frac{g_{s_5}}{g_{p_k}}\right).$$

Diese Deutung wird durch Untersuchung der „Umkehr“ der Neonlinien bestätigt, die ein ähnliches Anwachsen des Verhältnisses $V = N_{p_k}/N_{s_5} \cdot g_{s_5}/g_{p_k}$ zeigt. Aus den Messungen läßt sich unter gewissen theoretisch näher begründeten Annahmen über die Stromabhängigkeit der Atomdichte im s_5-Zustand das Verhältnis V und der Anstieg der N_{p_k}-Werte mit dem Strom berechnen (Fig. 6). Bei dem größten bisher erreichten Strom von 700 mA in einem 0,8 cm weiten Rohr nähern sich die N_p-Werte einem „Sättigungswert“, es scheint sich ein statistisches Gleichgewicht zwischen den Atomdichten in den verschiedenen Zuständen und den anregenden und vernichtenden Elektronen auszubilden. Definiert man die zu den s- und p-Zuständen gehörige spezifische Temperatur Θ durch die Formel

$$\ln V_{ps} = -\frac{E_p - E_s}{k\,\Theta_{sp}} = -\frac{h\,c}{k\,\lambda_{sp}}\,\frac{1}{\Theta_{sp}},$$

Untersuchungen über die anomale Dispersion angeregter Gase.

VI. Teil*.

Kontrollversuche für den Nachweis der negativen Dispersion:

Absorption, anomale Dispersion, Intensitätsverteilung und Intensität verschiedener Neonlinien**.

Von **R. Ladenburg** und **S. Levy** in Berlin-Dahlem.

Mit 4 Abbildungen. (Eingegangen am 12. August 1930.)

Die Deutung der in der vorangehenden Arbeit beschriebenen Versuche durch den Anstieg der p_k-Atome oberhalb 0,1 Amp./qcm und durch die dadurch bewirkte negative Dispersion wird auf zwei Weisen gestützt: Erstens durch Nachweis anomaler Dispersion an der Linie 7059 ($p_{10} - s_1''$) und Messung ihrer Absorption, die gerade im kritischen Stromgebiet merklich wird und rasch anwächst. Zweitens durch den Intensitätsanstieg der s—p-Linien. Die Untersuchung der Intensitätsverteilung im Innern dieser Linien in kurzer und in sehr langer Schicht mittels Perot-Fabry-Etalons zeigt, daß sie allein durch den Dopplereffekt bedingt ist; die Temperatur der emittierenden Atome bei 100 mA ist praktisch gleich der des Kühlwassers. Auf Grund der Kenntnis dieser Daten und der Werte $\mathfrak{R}$ läßt sich aus dem Intensitätsanstieg der Anstieg der Dichte der p_k-Atome mit dem Strom annähernd berechnen und zeigt sich wenigstens qualitativ mit den Ergebnissen der vorangehenden Arbeit in Übereinstimmung. Außerdem werden Messungen der anomalen Dispersion der $\mathfrak{R}$-Werte der s_2-Linien zwischen 20 und 400 mA mitgeteilt. In einem Anhang wird die Formel für die Intensität einer Spektrallinie bei Berücksichtigung der Absorption in endlicher Schichtdicke kurz abgeleitet.

1. Unsere Deutung der in der vorangehenden Arbeit (U.a.D. V.) beschriebenen Versuche über negative Dispersion an elektrisch erregtem Neon bei hohen Stromdichten beruht auf der Annahme, daß die Atomdichte der p_k-Zustände mit wachsendem Strom innerhalb des untersuchten Bereiches zunimmt und oberhalb von 50 mA einen relativ zur Dichte der s-Atome merkbaren Betrag besitzt (Termschema siehe U. a. D. V, Fig. 1).

Um diese Annahme zu prüfen, haben wir nach unmittelbaren Beweisen für den Anstieg der p_k-Atome im kritischen Stromgebiet gesucht

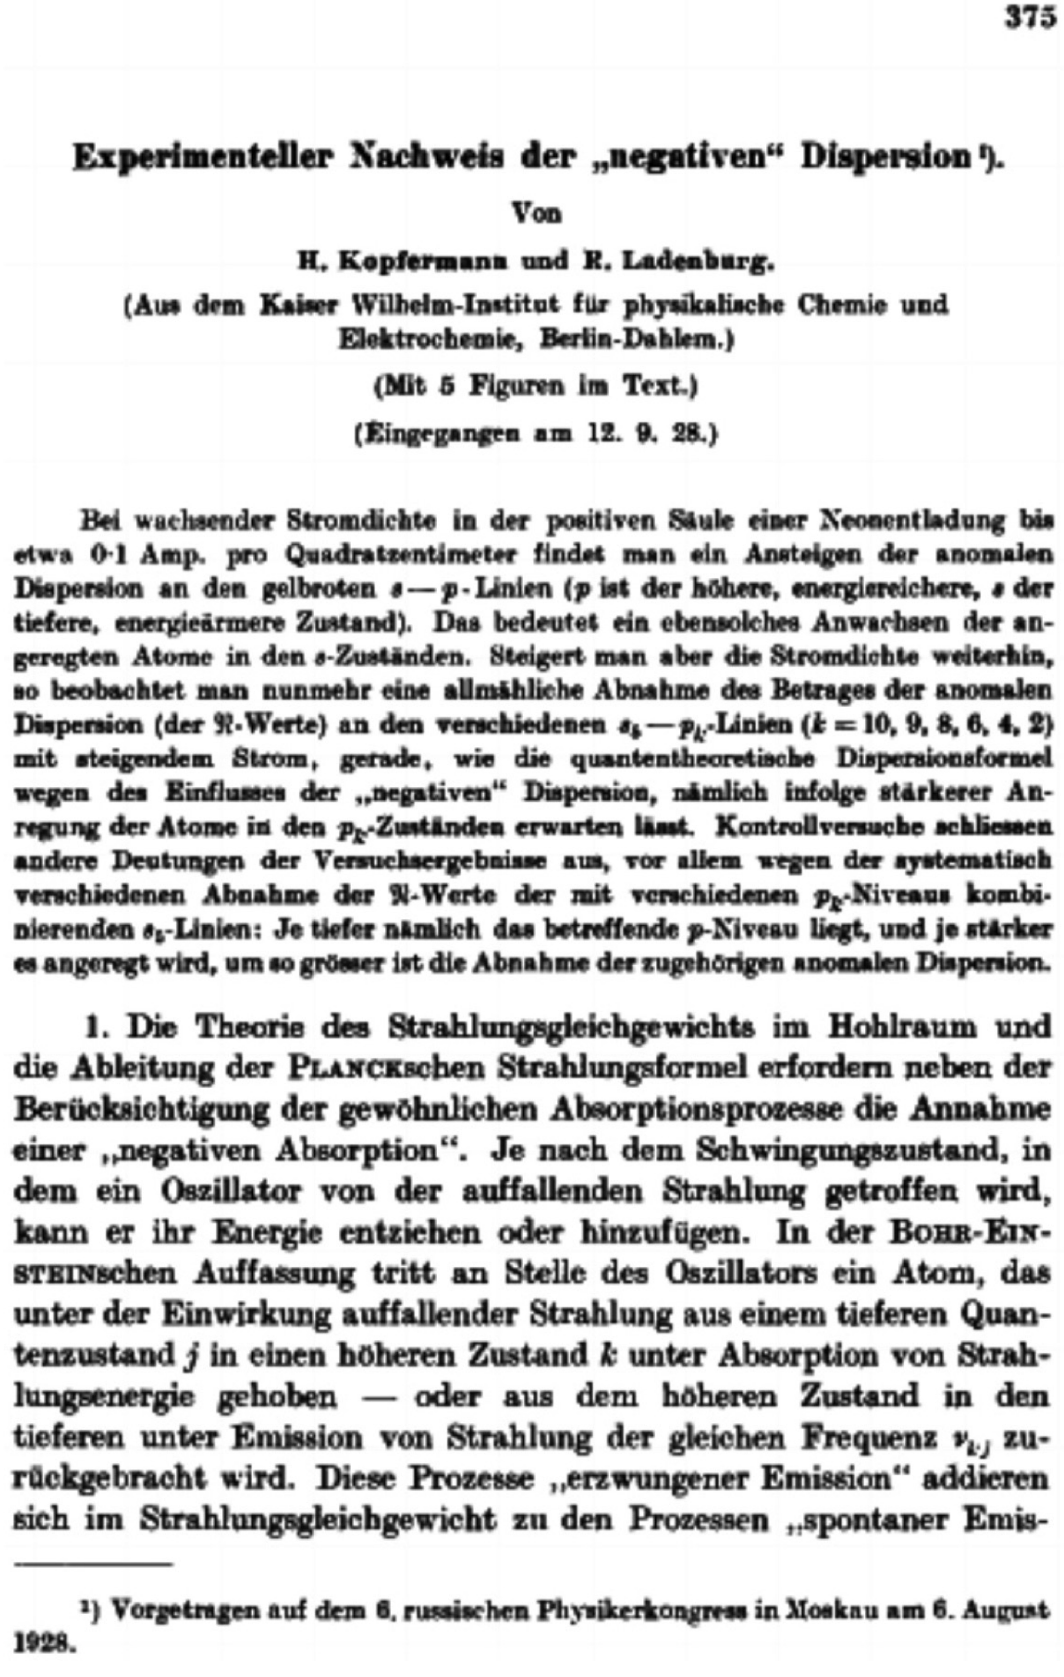
Figure C.69: Rudolf Ladenburg and other members of his group at the Kaiser Wilhelm Institut für Physikalische und Elektrochemie demonstrated stimulated light emission from atoms (amplification of the number of photons of light from atoms) during the period 1927–1931 [*Zeitschrift für Physik* (1930) 65:3–4:189–206].



Experimenteller Nachweis der „negativen“ Dispersion [1].

Von

H. Kopfermann und R. Ladenburg.

(Aus dem Kaiser Wilhelm-Institut für physikalische Chemie und Elektrochemie, Berlin-Dahlem.)

(Mit 5 Figuren im Text.)

(Eingegangen am 12. 9. 28.)

Bei wachsender Stromdichte in der positiven Säule einer Neonentladung bis etwa 0·1 Amp. pro Quadratzentimeter findet man ein Ansteigen der anomalen Dispersion an den gelbroten $s - p$-Linien (p ist der höhere, energiereichere, s der tiefere, energieärmere Zustand). Das bedeutet ein ebensolches Anwachsen der angeregten Atome in den s-Zuständen. Steigert man aber die Stromdichte weiterhin, so beobachtet man nunmehr eine allmähliche Abnahme des Betrages der anomalen Dispersion (der $\mathfrak{N}$-Werte) an den verschiedenen $s_k - p_k$-Linien ($k = 10, 9, 8, 6, 4, 2$) mit steigendem Strom, gerade, wie die quantentheoretische Dispersionsformel wegen des Einflusses der „negativen“ Dispersion, nämlich infolge stärkerer Anregung der Atome in den p_k-Zuständen erwarten lässt. Kontrollversuche schliessen andere Deutungen der Versuchsergebnisse aus, vor allem wegen der systematisch verschiedenen Abnahme der $\mathfrak{N}$-Werte der mit verschiedenen p_k-Niveaus kombinierenden s_k-Linien: Je tiefer nämlich das betreffende p-Niveau liegt, und je stärker es angeregt wird, um so grösser ist die Abnahme der zugehörigen anomalen Dispersion.

1. Die Theorie des Strahlungsgleichgewichts im Hohlraum und die Ableitung der Planckschen Strahlungsformel erfordern neben der Berücksichtigung der gewöhnlichen Absorptionsprozesse die Annahme einer „negativen Absorption“. Je nach dem Schwingungszustand, in dem ein Oszillator von der auffallenden Strahlung getroffen wird, kann er ihr Energie entziehen oder hinzufügen. In der Bohr-Einsteinschen Auffassung tritt an Stelle des Oszillators ein Atom, das unter der Einwirkung auffallender Strahlung aus einem tieferen Quantenzustand j in einen höheren Zustand k unter Absorption von Strahlungsenergie gehoben — oder aus dem höheren Zustand in den tieferen unter Emission von Strahlung der gleichen Frequenz ν_{kj} zurückgebracht wird. Diese Prozesse „erzwungener Emission“ addieren sich im Strahlungsgleichgewicht zu den Prozessen „spontaner Emis-

Untersuchungen über die Dispersion von Gasen und Dämpfen und ihre Darstellung durch die Dispersionstheorie.

I. Über die Dispersion des Quecksilberdampfes im Ultraviolett*.

Von **Rudolf Ladenburg** und **Günther Wolfsohn** in Berlin-Dahlem.

Mit 3 Abbildungen. (Eingegangen am 12. April 1930.)

Mit einem Jaminschen Interferometer aus Quarz wird die anomale Dispersion von gesättigtem Quecksilberdampf von bekanntem Druck und bekannter Temperatur in der Umgebung der Resonanzlinie 2537 untersucht. Die Oszillatorenstärke f, d. h. das Verhältnis $\mathfrak{N}/N$ der Zahl der Dispersionselektronen zur Gesamtzahl der Moleküle im Kubikzentimeter, wird in Abhängigkeit vom Dampfdruck im Bereich von 0,004 bis 200 mm gemessen. Zwischen 0,01 und 200 mm ergibt sich f konstant zu $0{,}0255 \pm 0{,}0005$. Unterhalb 0,01 mm ergeben die Messungen ein geringes Ansteigen des f-Wertes, das noch nicht erklärt werden kann. Aus den Messungen läßt sich, der Dampfdruckkurve $p = p\,(T)$ des Gesamtdruckes entsprechend, eine Kurve $\mathfrak{p} = \mathfrak{p}\,(T)$ ableiten, wobei $f^{-1} \cdot \mathfrak{p}$ den Partialdruck der Atome im Dampf darstellt. Wegen der Konstanz von f oberhalb 0,01 mm unterscheiden sich dort entsprechende Werte der Funktionen $p\,(T)$ und $\mathfrak{p}\,(T)$ nur um einen konstanten Faktor, und die Verdampfungswärme der Atome stimmt innerhalb eines Prozents mit derjenigen des gesamten Dampfes überein. Der Parialdruck der Moleküle im Dampf kann daher zwischen 0,01 und 200 mm Druck höchstens wenige Prozent ausmachen.

1. Ziel der Arbeit und Untersuchungsmethoden. Nach der heutigen Dispersionstheorie ist die Dispersion einatomiger Gase und Dämpfe quantitativ berechenbar, wenn die Eigenfrequenzen ν_0 — die Absorptionsstellen — und die zugehörigen f_0-Werte bekannt sind, das sind die Zahlen der den Frequenzen ν_0 entsprechenden Dispersionselektronen pro Atom. Tatsächlich sind zwar meist die ν_0-, aber nur in wenigen Fällen die f_0-Werte bekannt. Man hat daher bisher umgekehrt die f_0-Werte aus Dispersionsmessungen berechnet, indem man mit möglichst wenigen ν_0-Werten, also möglichst wenigen Gliedern in der Dispersionsformel auszukommen suchte**.

II. Die Dispersion von Quecksilberdampf zwischen 7500 und 2650 Å.

Von **Günther Wolfsohn** in Berlin-Dahlem.

Mit 1 Abbildung. (Eingegangen am 12. April 1930.)

Mit Hilfe der in der vorhergehenden Arbeit beschriebenen Apparatur werden Dispersionsmessungen von Hg-Dampf zwischen 7500 und 2650 Å durchgeführt. Die Dispersionskurve zeigt den theoretisch zu erwartenden Verlauf und läßt sich mit Hilfe einer dreigliedrigen Dispersionsformel darstellen, die als Eigenwellenlängen außer den Absorptionslinien $\lambda = 2537$ und 1850 Å eine dritte enthält, die die höheren Glieder der Hauptserie und das anschließende Kontinuum zusammenfaßt. Das von Herzfeld und Wolf vermutete Gebiet anomaler Dispersion bei $\lambda = 6900$ Å erweist sich als nicht reell.

Dispersionsmessungen an Hg-Dampf sind bereits von Cuthbertson und Metcalfe* und von McLennan** gemacht worden. Zur Untersuchung diente das Jaminsche Interferometer. McLennan benutzte außerdem ein Hohlprisma, das mit gesättigtem Hg-Dampf gefüllt wurde. Die Messungen beider Forscher erstrecken sich auf einzelne Wellenlängen des sichtbaren Spektralgebietes, sie erfolgten visuell durch Zählung der beim Verdampfen bzw. Kondensieren des Hg-Dampfes im Gesichtsfeld vorbeiwandernden Streifen oder bei den Messungen mit Prisma durch goniometrische Bestimmung des Ablenkungswinkels. McLennan arbeitete mit gesättigtem Dampf. Cuthbertson verdampfte eine vorher abgewogene Menge Hg vollständig und bestimmte durch Rechnung die Dichte des im Strahlengang befindlichen Dampfes.

Die Ergebnisse von Cuthbertson und McLennan sind von Herzfeld und Wolf*** diskutiert worden. Diese kommen zu dem Ergebnis, daß die Dispersion von Hg-Dampf unter der Annahme der bekannten ultravioletten

III. Die Dispersion des Sauerstoffs zwischen 6000 und 1920 Å.

Von **R. Ladenburg** und **G. Wolfsohn** in Berlin-Dahlem.

Mit 3 Abbildungen. (Eingegangen am 6. August 1932.)

Dispersionsmessungen des Sauerstoffs bis herab zu 1920 Å, die mit einem neu konstruierten Interferometer ausgeführt sind, lassen sich durch eine Dispersionsformel mit drei Gliedern gut darstellen. Die Konstanten sind: $\lambda_1 = 1899$ Å, $f_1 = 4{,}0 \cdot 10^{-5}$, $\lambda_2 = 1468$ Å, $f_2 = 0{,}20$, $\lambda_3 = 544$ Å, $f_3 = 5{,}93$. Die erstgenannte Eigenfrequenz entspricht der Absorptionsteilbande $v'' = 0 \rightarrow v' = 5$ des Schumann-Runge-Systems, deren Kante bei 1903 Å liegt, der zugehörige f-Wert einer mittleren Übergangswahrscheinlichkeit einer einzelnen Rotationslinie $A \sim 4 \cdot 10^4$. λ_2 ist der Schwerpunkt des an die Konvergenzstelle der Schumann-Runge-Banden bei 1750 Å anschließenden Kontinuums, das sich bis 1300 Å erstreckt, wie durch anderweitige Absorptionsmessungen bestätigt wird. $f_2 = 0{,}20$ ist der Integralwert der gesamten Bande einschließlich Kontinuum, entspricht also dem zugehörigen Elektronensprung. λ_3 ist als Schwerpunkt eines oder mehrerer Bandensysteme im kurzwelligen Ultraviolett anzusehen; das zugehörige Absorptionsgebiet reicht von 1300 bis unter 300 Å.

Wir haben in früheren Arbeiten¹) den Einfluß der ultravioletten Absorptionslinien auf die Dispersion des Quecksilberdampfes gemessen und die Gültigkeit der quantentheoretischen Dispersionsformel nachgewiesen. Der Zweck der vorliegenden Versuche und weiterer geplanter Arbeiten ist, diese Untersuchungen auch auf mehratomige Gase auszudehnen und festzustellen, wieweit es möglich ist, die Dispersion solcher Gase auf den Einfluß der Absorptionslinien und des kontinuierlichen Teils ihres Bandenspektrums zurückzuführen. Hierbei interessierte uns in erster Linie, die Lage der aus den Dispersionsmessungen berechneten Eigenfrequenzen mit dem Absorptionsspektrum zu vergleichen sowie aus den Zählern der Dispersionsglieder Übergangswahrscheinlichkeiten für die verschiedenen möglichen Quantensprünge zu berechnen. In zweiter Linie war beabsichtigt, womöglich an den einzelnen Linien einer Teilbande anomale Dispersion nachzuweisen. Als Objekt für unsere Untersuchungen haben wir zunächst den

Untersuchungen über die Dispersion von Gasen und Dämpfen und ihre Darstellung durch die Dispersionstheorie.

IV. Dispersion von Quecksilberdampf zwischen 2800 und 1890 Å und Lebensdauer des Hg $7p\,^1P_1$-Zustandes.

Von **G. Wolfsohn** z. Z. Berlin-Charlottenburg.

Mit 3 Abbildungen. (Eingegangen am 21. Februar 1933.)

Im Anschluß an früher ausgeführte Messungen der Dispersion von Quecksilberdampf zwischen 7000 und 2700 Å werden mit einem Interferometer nach Jamin-Mach mit Flußspatoptik Dispersionsmessungen zwischen 2800 und 1890 Å ausgeführt. Die Dispersion von Hg-Dampf zwischen 7000 und 1890 Å wird durch eine dreigliedrige Dispersionsformel dargestellt. Das erste Glied entspricht dem Einfluß der Interkombinationslinie $6\,s\,^1S_0 - 7\,p\,^3P_1$ $\lambda = 2537$ Å auf die Dispersion, das zweite demjenigen der Linie $6\,s\,^1S_0 - 7\,p\,^1P_1$ $\lambda = 1850$ Å. Durch das dritte Glied wird dem Einfluß der weiter im Ultravioletten liegenden Eigenfrequenzen Rechnung getragen. Der f-Wert der Linie 1850 ergibt sich zu $1{,}19 \pm 0{,}02$. Hieraus erhält man für die Übergangswahrscheinlichkeit des zugehörigen Quantensprungs den Wert $A = 7{,}70 \cdot 10^8$, für die Lebensdauer des $7\,p\,^1P_1$-Zustandes $T = 1{,}30 \cdot 10^{-9}$.

Messungen der Dispersion von Hg-Dampf, die ich früher im Spektralgebiet von 7500 bis 2700 Å ausgeführt habe¹), haben ergeben, daß die Dispersionskurve sich erwartungsgemäß durch eine Formel

$$n_0 - 1 = \frac{e^2 N_0}{2\pi m c^2} \sum_i \frac{f_i \lambda^2 \lambda_i^2}{\lambda^2 - \lambda_i^2} = \frac{e^2 N_0}{2\pi m c^2} \sum_i \frac{f_i}{\nu_i^2 - \nu^2} \qquad (1)$$

für den Brechungsquotienten n_0 darstellen läßt (e, m Elektronenladung bzw. -masse, c Lichtgeschwindigkeit). Da man den Brechungsquotienten auf einen fiktiven Dampf von 0° und 760 mm Druck bezieht, der bei Hg die Dichte 0,00895 g/cm³ besitzt, so ist N_0 gleich der Avogradroschen Zahl pro Kubikzentimeter zu setzen. Zur Darstellung der Meßergebnisse mußten in Formel (1) drei ultraviolette Eigenfrequenzen angenommen werden, von

V. Ein Interferometer für Dispersionsmessungen im Schumanngebiet.

Von **G. Wolfsohn,** zur Zeit in Utrecht.

Mit 1 Abbildung. (Eingegangen am 4. Juli 1933.)

Beschreibung eines Jamin-Machschen Interferometers mit Flußspatoptik, bei dem der optische Strahlengang ganz im Vakuum geführt ist und das in Verbindung mit einem Vakuumflußspatspektrographen für Dispersionsmessungen im Schumanngebiet geeignet ist. Vorläufige Messungen der anomalen Dispersion an der Hg-Linie 1850 Å mit dem Ergebnis $f = 1,3 \pm 0,15$ für den f-Wert dieser Linie.

Kürzlich haben R. Ladenburg und ich in dieser Zeitschrift[1]) eine abgeänderte Konstruktion des Jaminschen Interferometers beschrieben, bei dem jede der beiden mehrere Zentimeter dicken aus Glas oder Quarz bestehenden Interferometerplatten durch eine 5 mm dicke halbdurchlässig platinierte Flußspatplatte und einen mit einer Hochheimschen Silicium-Silberlegierung belegten Planspiegel ersetzt wird, die durch ein planparalleles Distanzstück aus Invarstahl in festem Abstand miteinander verbunden sind (vgl. J in Fig. 1). Mit dieser Anordnung konnten in Verbindung mit einem Quarzspektrographen Dispersionsmessungen bis an die Grenze des Schumanngebietes ausgeführt werden[2]). Ein solches Interferometer erhält jedoch, wie daselbst betont ist, seine volle Leistungsfähigkeit für Messungen im Ultraviolett erst dann, wenn man den gesamten optischen Strahlengang ins Vakuum verlegt und an Stelle des Quarzspektrographen einen Vakuumflußspatspektrographen verwendet. Mit einer solchen Anordnung, die im folgenden beschrieben wird, konnten in der Tat mit einer lichtstarken Wasserstoffentladung als Lichtquelle Interferenzstreifen bis 1500 Å photographiert werden. Damit wird ein für Dispersionsmessungen wichtiges Spektralgebiet der Messung zugänglich gemacht.

PROTECTIVE GLASS

Franz Weidert, Berlin-Schoneberg, and Hans Löffler, Berlin-Lichterfelde, Germany, assignors to Degea Aktiengesellschaft (Auergesellschaft), Berlin, Germany, a corporation of Germany

No Drawing. Application May 21, 1937, Serial No. 143,936. In Germany May 25, 1936

16 Claims. (Cl. 106—36.1)

Prior to our present invention, various expedients have been proposed to obtain glasses which reduce or eliminate rays, and particularly ultra-violet rays, liable to produce injurious effects. One type of glass introduced for this purpose contained a considerable addition of neodymium, as neodymium oxide (generally in the form of commercial didymia, about 60% of which consists of neodymium oxide, Nd_2O_3). Besides the protective effect referred to above, such glasses containing a considerable proportion of neodymium have the valuable advantage that objects viewed through them exhibit richer color contrasts, that is, red, green and blue appear intensified or more vivid. The absorption obtained with protective glasses of this type as made hitherto, was insufficient for some purposes. Even if it were practicable to introduce neodymium into the glass in extremely high concentration, the absorption would still remain relatively slight in the ultra-violet region. Efficient absorption in that region is however indispensable when the glass is to be used for aviator's goggles, snow-glasses, etc. It would indeed be possible, by an addition of cerium (in the form of cerium oxide), to increase the absorption within the ultra-violet region. Even this would not be sufficient for the purposes mentioned above. Furthermore, the addition of cerium will not reduce the amount of visible light transmitted through the glass.

The object of our invention is to increase the total absorption of light, that is to say, not only to absorb the invisible ultra-violet rays effectively, but also to damp or tone down the transmission of the visible light rays. For instance, the absorption of the ultra-violet rays may be substantially complete, and the visible light may be reduced by absorption to, for example, 30% of its original amount.

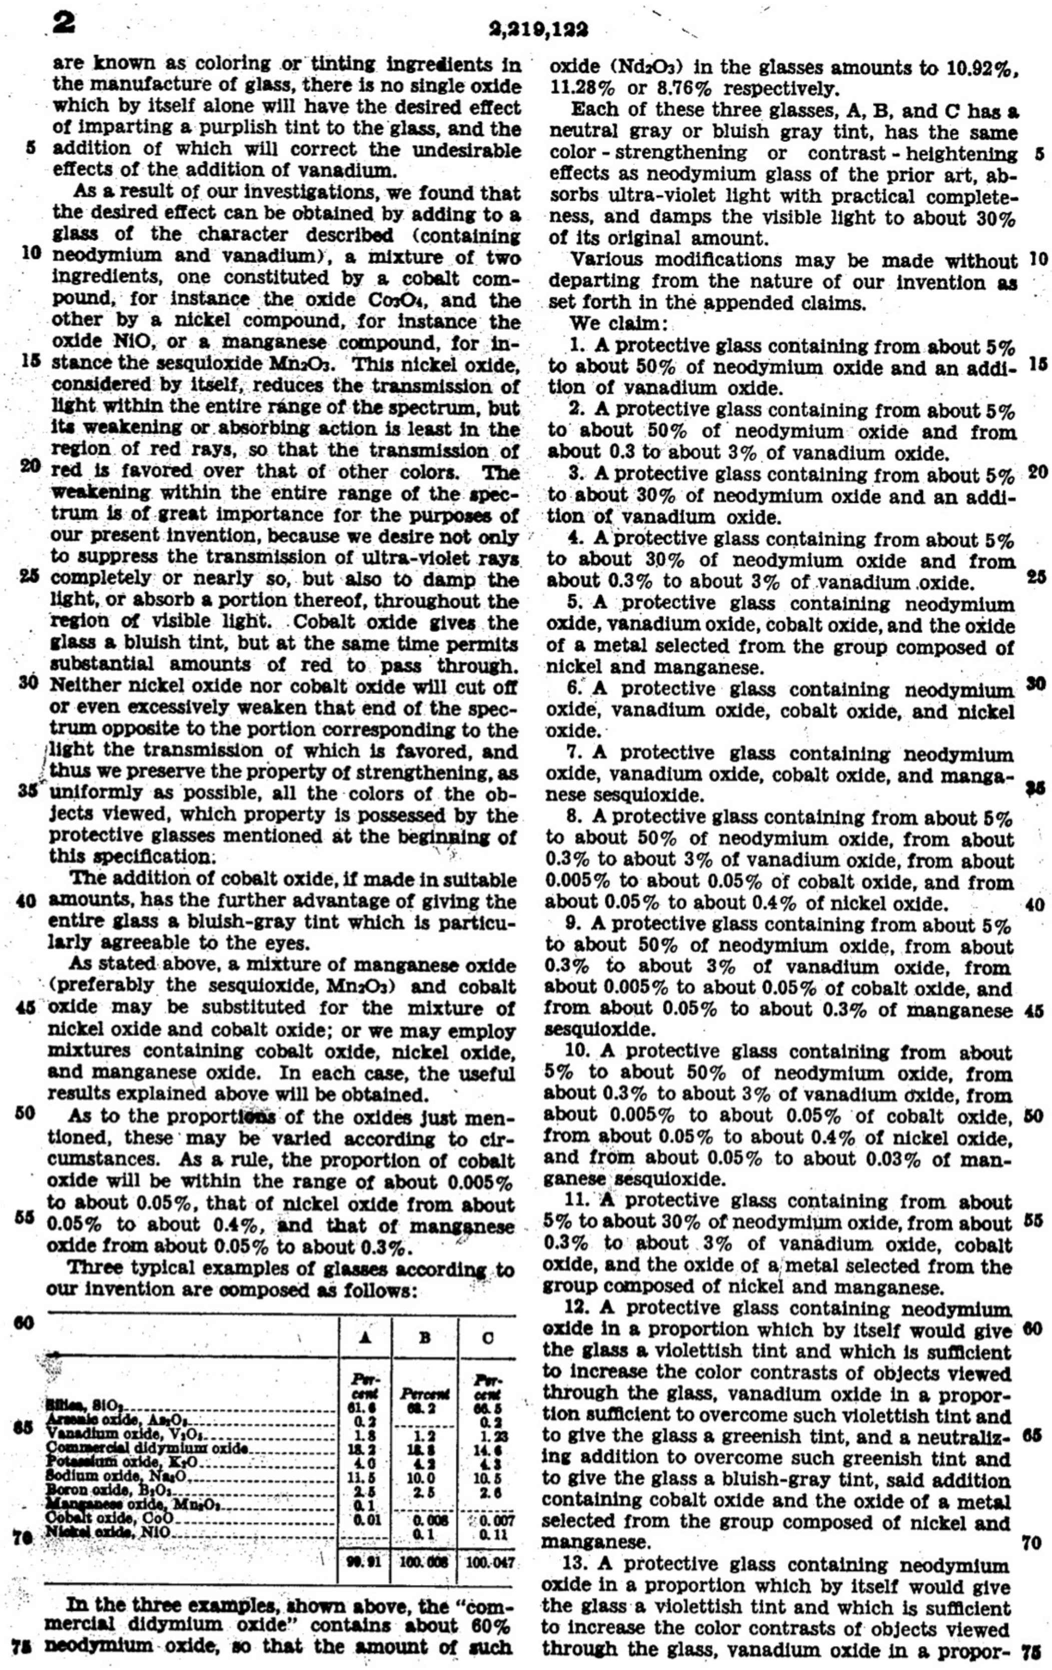
In order to obtain these results, we employ glass containing oxides of neodymium, of vanadium, and oxides of certain additional metals which correct the disagreeable greenish tint observed when vanadium oxide is incorporated in glass without such corrective additions.

In carrying out our invention, we employ glass containing a relatively high percentage of neodymium oxide, Nd_2O_3, that is to say, a percentage sufficient to increase the color contrasts of objects viewed through the glass. Such percentage may range from about 5% to about 50%. The desired absorptive effects are obtained within this entire range. However, there are certain practical difficulties in the manufacture and working of glass containing the higher percentages of neodymium oxide (above 30%), and for this reason the percentage of neodymium oxide used by us ranges generally from about 5% to about 30%.

In addition to the neodymium oxide, our improved glass contains, as an important ingredient, an amount of vanadium (as vanadium oxide, preferably the pentoxide, V_2O_5) sufficient to produce the desired results, that is, an extremely strong absorption of light in the ultra-violet region and simultaneously a damping or toning down in the region of the visible light. It has been found that if this double effect is to be obtained by the addition of vanadium to glass containing a relatively high percentage of neodymium oxide, a fairly high proportion of vanadium (for instance, as V_2O_5) must be employed, say from about 0.3% to about 3%. While this will produce the desired strong absorption in the ultra-violet region and a reduction of the perviousness of the glass to visible rays, it is accompanied by the production of a greenish stain or tint, owing to the fact that the green tint due to the addition of vanadium oxide is sufficiently powerful to overcome or outweight the violettish tint given to the glass by the neodymium oxide. The greenish tint which the glass assumes when it contains both neodymium and vanadium in the relatively high proportions mentioned above, gives the glass an unpleasant appearance. Furthermore, such glass no longer intensifies with substantially uniform strength, all the colors viewed therethrough, lacking therefore this property which is possessed by glass containing neodymium oxide but no vanadium oxide. We may add that glass containing vanadium but no neodymium has a very pronounced unpleasant greenish tint and lacks the uniform strengthening of the colors just referred to above.

We have endeavored to produce a glass containing both neodymium oxide and vanadium oxide yet free from the detrimental and disturbing secondary effects of vanadium which have been pointed out above. That is to say, we have sought for a remedy that would remove or neutralize the greenish tint due to the presence of vanadium, give the glass an agreeable neutral grayish or bluish-gray tint, and preserve the contrast-heightening effect due to the presence of neodymium. It might have been assumed that such a remedy would be afforded by adding some coloring matter which, considered by itself, would impart a purplish tint to the glass. We found, however, that among the various oxides which

Figure C.76: In 1934, Franz Weidert and Hans Löffler invented neodymium glass with unusual spectral properties that made it suitable for a variety of optical applications (ultimately including neodymium glass lasers).



2 2,219,122

are known as coloring or tinting ingredients in the manufacture of glass, there is no single oxide which by itself alone will have the desired effect of imparting a purplish tint to the glass, and the addition of which will correct the undesirable effects of the addition of vanadium.

As a result of our investigations, we found that the desired effect can be obtained by adding to a glass of the character described (containing neodymium and vanadium), a mixture of two ingredients, one constituted by a cobalt compound, for instance the oxide Co_3O_4, and the other by a nickel compound, for instance the oxide NiO, or a manganese compound, for instance the sesquioxide Mn_2O_3. This nickel oxide, considered by itself, reduces the transmission of light within the entire range of the spectrum, but its weakening or absorbing action is least in the region of red rays, so that the transmission of red is favored over that of other colors. The weakening within the entire range of the spectrum is of great importance for the purposes of our present invention, because we desire not only to suppress the transmission of ultra-violet rays completely or nearly so, but also to damp the light, or absorb a portion thereof, throughout the region of visible light. Cobalt oxide gives the glass a bluish tint, but at the same time permits substantial amounts of red to pass through. Neither nickel oxide nor cobalt oxide will cut off or even excessively weaken that end of the spectrum opposite to the portion corresponding to the light the transmission of which is favored, and thus we preserve the property of strengthening, as uniformly as possible, all the colors of the objects viewed, which property is possessed by the protective glasses mentioned at the beginning of this specification.

The addition of cobalt oxide, if made in suitable amounts, has the further advantage of giving the entire glass a bluish-gray tint which is particularly agreeable to the eyes.

As stated above, a mixture of manganese oxide (preferably the sesquioxide, Mn_2O_3) and cobalt oxide may be substituted for the mixture of nickel oxide and cobalt oxide; or we may employ mixtures containing cobalt oxide, nickel oxide, and manganese oxide. In each case, the useful results explained above will be obtained.

As to the proportions of the oxides just mentioned, these may be varied according to circumstances. As a rule, the proportion of cobalt oxide will be within the range of about 0.005% to about 0.05%, that of nickel oxide from about 0.05% to about 0.4%, and that of manganese oxide from about 0.05% to about 0.3%.

Three typical examples of glasses according to our invention are composed as follows:

	A	B	C
	Percent	Percent	Percent
Silica, SiO_2	61.6	68.2	66.5
Arsenic oxide, As_2O_3	0.2		0.2
Vanadium oxide, V_2O_5	1.8	1.2	1.23
Commercial didymium oxide	18.2	13.8	14.6
Potassium oxide, K_2O	4.0	4.2	4.3
Sodium oxide, Na_2O	11.5	10.0	10.5
Boron oxide, B_2O_3	2.5	2.5	2.6
Manganese oxide, Mn_2O_3	0.1		
Cobalt oxide, CoO	0.01	0.008	0.007
Nickel oxide, NiO		0.1	0.11
	99.91	100.008	100.047

In the three examples, shown above, the "commercial didymium oxide" contains about 60% neodymium oxide, so that the amount of such oxide (Nd_2O_3) in the glasses amounts to 10.92%, 11.28% or 8.76% respectively.

Each of these three glasses, A, B, and C has a neutral gray or bluish gray tint, has the same color-strengthening or contrast-heightening effects as neodymium glass of the prior art, absorbs ultra-violet light with practical completeness, and damps the visible light to about 30% of its original amount.

Various modifications may be made without departing from the nature of our invention as set forth in the appended claims.

We claim:

1. A protective glass containing from about 5% to about 50% of neodymium oxide and an addition of vanadium oxide.

2. A protective glass containing from about 5% to about 50% of neodymium oxide and from about 0.3 to about 3% of vanadium oxide.

3. A protective glass containing from about 5% to about 30% of neodymium oxide and an addition of vanadium oxide.

4. A protective glass containing from about 5% to about 30% of neodymium oxide and from about 0.3% to about 3% of vanadium oxide.

5. A protective glass containing neodymium oxide, vanadium oxide, cobalt oxide, and the oxide of a metal selected from the group composed of nickel and manganese.

6. A protective glass containing neodymium oxide, vanadium oxide, cobalt oxide, and nickel oxide.

7. A protective glass containing neodymium oxide, vanadium oxide, cobalt oxide, and manganese sesquioxide.

8. A protective glass containing from about 5% to about 50% of neodymium oxide, from about 0.3% to about 3% of vanadium oxide, from about 0.005% to about 0.05% of cobalt oxide, and from about 0.05% to about 0.4% of nickel oxide.

9. A protective glass containing from about 5% to about 50% of neodymium oxide, from about 0.3% to about 3% of vanadium oxide, from about 0.005% to about 0.05% of cobalt oxide, and from about 0.05% to about 0.3% of manganese sesquioxide.

10. A protective glass containing from about 5% to about 50% of neodymium oxide, from about 0.3% to about 3% of vanadium oxide, from about 0.005% to about 0.05% of cobalt oxide, from about 0.05% to about 0.4% of nickel oxide, and from about 0.05% to about 0.03% of manganese sesquioxide.

11. A protective glass containing from about 5% to about 30% of neodymium oxide, from about 0.3% to about 3% of vanadium oxide, cobalt oxide, and the oxide of a metal selected from the group composed of nickel and manganese.

12. A protective glass containing neodymium oxide in a proportion which by itself would give the glass a violettish tint and which is sufficient to increase the color contrasts of objects viewed through the glass, vanadium oxide in a proportion sufficient to overcome such violettish tint and to give the glass a greenish tint, and a neutralizing addition to overcome such greenish tint and to give the glass a bluish-gray tint, said addition containing cobalt oxide and the oxide of a metal selected from the group composed of nickel and manganese.

13. A protective glass containing neodymium oxide in a proportion which by itself would give the glass a violettish tint and which is sufficient to increase the color contrasts of objects viewed through the glass, vanadium oxide in a propor-

2,219,122 **3**

tion sufficient to overcome such violettish tint and to give the glass a greenish tint, and a neutralizing addition to overcome such greenish tint and to give the glass a bluish-gray tint, said addition containing cobalt oxide and nickel oxide.

14. A protective glass containing neodymium oxide in a proportion which by itself would give the glass a violettish tint and which is sufficient to increase the color contrasts of objects viewed through the glass, vanadium oxide in a proportion sufficient to overcome such violettish tint and to give the glass a greenish tint, and a neutralizing addition to overcome such greenish tint and to give the glass a bluish-gray tint, said addition containing cobalt oxide and manganese sesquioxide.

15. A protective glass containing neodymium oxide in a proportion which by itself would give the glass a violettish tint and which is sufficient to increase the color contrasts of objects viewed through the glass, vanadium oxide in a proportion sufficient to overcome such violettish tint and to give the glass a greenish tint, and a neutralizing addition to overcome such greenish tint and to give the glass a bluish-gray tint, said addition containing cobalt oxide, nickel oxide, and manganese sesquioxide.

16. A protective glass containing from about 5 to 50% of neodymium oxide, an amount of vanadium oxide corresponding to about from 10 to 14% of the neodymium oxide content, an amount of cobalt oxide corresponding to about at least 0.5% of the vanadium oxide content, and an addition consisting of the oxide of a metal selected from the group consisting of nickel and manganese, said addition amounting to from about 5 to 9% of the vanadium oxide content.

FRANZ WEIDERT.
HANS LÖFFLER.

Figure C.78: In 1934, Franz Weidert and Hans Löffler invented neodymium glass with unusual spectral properties that made it suitable for a variety of optical applications (ultimately including neodymium glass lasers).

[Neodymium-doped glass is now widely used to make lasers, especially high-power laser systems. Due to the optical properties of the neodymium glass, that material absorbs ordinary, visible, incoherent light (such as light from photographic flash lamps) and emits infrared coherent (laser) light with a wavelength of approximately 1.06 μm.

As illustrated by the preceding U.S. Patent 2,219,122 and the following FIAT 824 report, Franz Weidert (German, 1878–1954) and Hans Löffler (German, ??–??) invented neodymium glass in or before 1934, and filed several patent applications from 1934 onward. They described its unusual spectral properties and developed a wide variety of optical applications for it.

FIAT 824 (p. 3132) stated that much of the optical industry of the German-speaking world was located in areas that were taken over by Russian forces after the war (Russian-occupied zones of Germany and Austria, and also Czech and Polish territory). Therefore even after the war, Western Allied countries did not have much information regarding just how far neodymium glass and other potentially laser-related optical technologies had advanced in the German-speaking world by 1945.

However, it is clear that scientists in the German-speaking world:

- Had been working with neodymium-doped glass since at least 1934 and were fully aware of its spectral properties and potential optical applications that those enabled (pp. 3128–3132).

- Were well aware of the high-profile publications by Albert Einstein, Walther Bothe, James Franck, Rudolf Ladenburg, and others during the period 1916–1931 demonstrating the theoretical feasibility and experimental evidence for stimulated emission of light in laser-like optical systems (pp. 3102–3127).

- Were keenly interested in developing monochromatic light sources—something like a laser that would only emit light of one particular wavelength (pp. 3137–3156).

- Were doing extensive research on new methods of producing and detecting infrared light, as well as developing a wide variety of applications of infrared light (pp. 1131–1156).

Given all of these known facts, it is not unreasonable to wonder whether laser-like applications of neodymium glass may have been proposed or investigated in wartime Germany, or whether such work may have influenced the development of neodymium glass lasers in other countries after the war.

According to official histories, neodymium lasers were first demonstrated in 1961 in the United States [Bromberg 1991, p. 101]. Was that development directly or indirectly aided by the large amount of advanced optical materials, information, and scientists that the United States obtained from Germany and Austria at the end of World War II (see for example pp. 624–642, 680–688, 1131–1156, 1260–1285, and 2923–3018)?

Much more archival research needs to be conducted to investigate these questions and the relevant history.]

FIAT 824. ***The Miscellaneous Glass Industry of Central Europe.***

[p. 1:] This report presents the results of an extensive study of the miscellaneous glass industry in the British, French, and American Occupied Zones of Germany and Austria, from December 1945 to May 1946. [...] Much of the German and Austrian glass industry is located in the Russian Zone from which no direct information could be obtained. In many instances this presented unusual difficulties arising from the fact that suppliers of equipment and materials, as well as glass manufacturing plants, were not accessible. [...]

[pp. 3–4:] Rare earths are in wide use in the production of special glasses, particularly ultra-violet and infra-red absorbing protective glasses. Cerium is commonly used in the form of ignited cerium dioxide. Several grades of neodymium compounds of varying purity were found to be in use[...]

[p. 31:] A glass of relatively high neodymium content has come into rather wide use during the war under the trade name of Neophan (See Table 15 Appendix 4). Glasses containing neodymium have been used for spectacles and other special purposes for some time, and even the Neophan series have been known from the Weidert patents, but the wide extent and purposes of its more recent use seem worthy of comment. These glasses have been used for sun glasses, for military aviators and anti-aircraft crews, for locomotive engineers, and in short, for all purposes for which the readier and more precise discrimination among colors, particularly signal colors, is of importance. They have also been used for illuminating ball rooms and butcher shops to yield more desirable color observations. They have been used as mirrors in hospitals, since the patients think that they "look better" when they view themselves in such mirrors. It is believed that the compositions used for all of these purposes are variants of the composition listed. The essential feature apparently resides in the characteristic neodymium absorption bands. ist als Erfinder genannt worden.

Franz Focke in Bromberg

Anordnung zur Erzeugung von Lichtstrahlen mittels gasgefüllter Entladungsräume, die mit Hochfrequenzstrom betrieben werden

Patentiert im Deutschen Reich vom 15. Oktober 1940 an

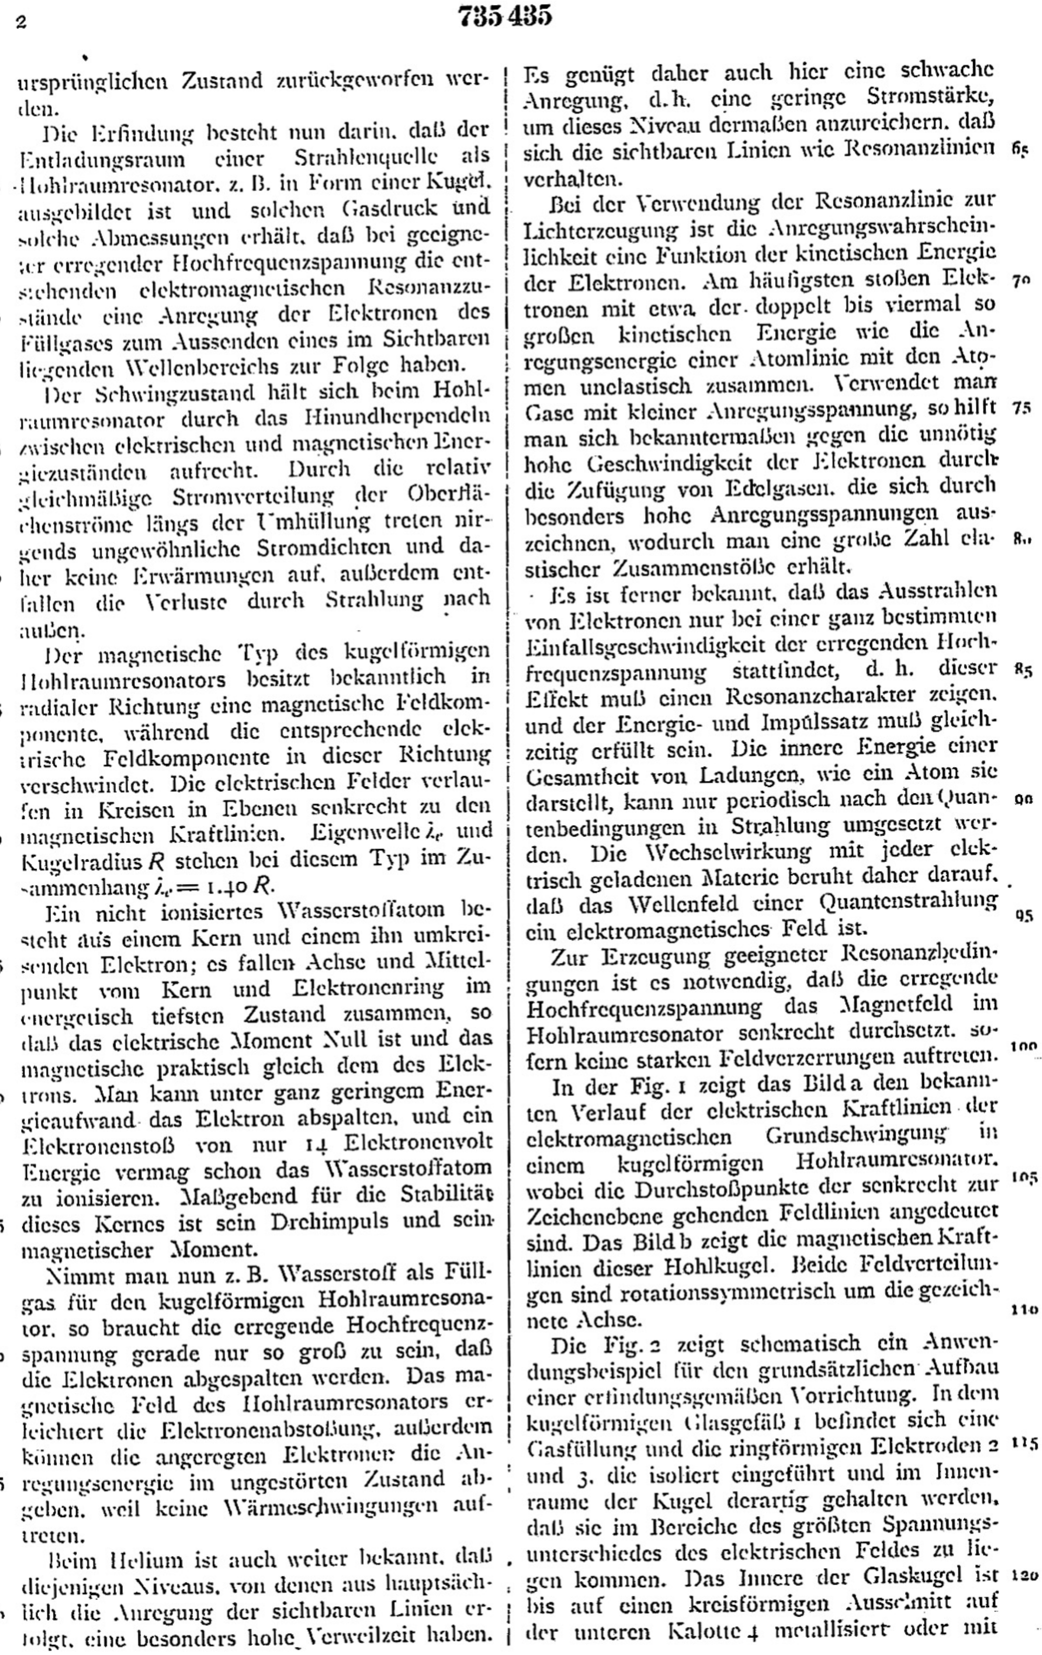
Patenterteilung bekanntgemacht am 8. April 1943

Es ist bekannt, Licht mittels gas- oder metalldampfgefüllter Entladungsröhren zu erzeugen, die unter Überlagerung eines Hochfrequenzstromes betrieben werden. Man erhält dadurch eine gewisse Steigerung der Lichterzeugung, weil die zum Erzielen einer bestimmten Lichtintensität erforderliche Betriebsspannung im Gebiet der ultrakurzen Frequenzen über etwa 10^7 Hertz bedeutend kleiner ist als bei Niederfrequenz. Eine wesentlich rentablere Lichterzeugung wurde jedoch dadurch nicht erzielt.

Die vorliegende Erfindung geht nun von der Erkenntnis aus, daß die Lichterzeugung dann wirtschaftlicher gestaltet werden kann, wenn man bei gleichzeitiger Anordnung von Mitteln zur leichteren Überwindung der Stabilität der Füllgasatome auch Vorkehrungen trifft, daß die angeregten Atome die Anregungsenergie im ungestörten Zustande abgeben können.

Die Lichtstrahlen werden bekanntlich von den die Atomkerne umkreisenden Elektronen ausgesendet. Spektroskopische Tatsachen führten zur Erkenntnis, daß die Elektronen eine Eigenrotation und damit ein magnetisches Feld besitzen. Wenn nun Elektronen in den Kern eingebaut sind, so ist zu erwarten, daß dieser ebenfalls ein magnetisches Feld besitzt, und zwar zumindestens dann, wenn die Zahl der Kernelektronen ungerade ist. Von Bedeutung ist ferner, daß die mittlere Verweildauer der Elektronen in angeregtem Zustande temperaturabhängig ist; bei tiefen Temperaturen bleibt der angeregte Zustand erhalten, während bei hohen Temperaturen die angeregten Elektronen durch die Wärmeschwingungen der Atome rasch in den

Figure C.79: In 1940, Franz Focke filed a patent application on using resonant excitation to create a population inversion of electron energy levels in a gas, in order to create a light beam with a particular wavelength.



2 **735 435**

ursprünglichen Zustand zurückgeworfen werden.

Die Erfindung besteht nun darin, daß der Entladungsraum einer Strahlenquelle als Hohlraumresonator, z. B. in Form einer Kugel, ausgebildet ist und solchen Gasdruck und solche Abmessungen erhält, daß bei geeigneter erregender Hochfrequenzspannung die entstehenden elektromagnetischen Resonanzzustände eine Anregung der Elektronen des Füllgases zum Aussenden eines im Sichtbaren liegenden Wellenbereichs zur Folge haben.

Der Schwingzustand hält sich beim Hohlraumresonator durch das Hinundherpendeln zwischen elektrischen und magnetischen Energiezuständen aufrecht. Durch die relativ gleichmäßige Stromverteilung der Oberflächenströme längs der Umhüllung treten nirgends ungewöhnliche Stromdichten und daher keine Erwärmungen auf, außerdem entfallen die Verluste durch Strahlung nach außen.

Der magnetische Typ des kugelförmigen Hohlraumresonators besitzt bekanntlich in radialer Richtung eine magnetische Feldkomponente, während die entsprechende elektrische Feldkomponente in dieser Richtung verschwindet. Die elektrischen Felder verlaufen in Kreisen in Ebenen senkrecht zu den magnetischen Kraftlinien. Eigenwelle λ_e und Kugelradius R stehen bei diesem Typ im Zusammenhang $\lambda_e = 1.40\, R$.

Ein nicht ionisiertes Wasserstoffatom besteht aus einem Kern und einem ihn umkreisenden Elektron; es fallen Achse und Mittelpunkt vom Kern und Elektronenring im energetisch tiefsten Zustand zusammen, so daß das elektrische Moment Null ist und das magnetische praktisch gleich dem des Elektrons. Man kann unter ganz geringem Energieaufwand das Elektron abspalten, und ein Elektronenstoß von nur 14 Elektronenvolt Energie vermag schon das Wasserstoffatom zu ionisieren. Maßgebend für die Stabilität dieses Kernes ist sein Drehimpuls und sein magnetischer Moment.

Nimmt man nun z. B. Wasserstoff als Füllgas für den kugelförmigen Hohlraumresonator, so braucht die erregende Hochfrequenzspannung gerade nur so groß zu sein, daß die Elektronen abgespalten werden. Das magnetische Feld des Hohlraumresonators erleichtert die Elektronenabstoßung, außerdem können die angeregten Elektronen die Anregungsenergie im ungestörten Zustand abgeben, weil keine Wärmeschwingungen auftreten.

Beim Helium ist auch weiter bekannt, daß diejenigen Niveaus, von denen aus hauptsächlich die Anregung der sichtbaren Linien erfolgt, eine besonders hohe Verweilzeit haben. Es genügt daher auch hier eine schwache Anregung, d. h. eine geringe Stromstärke, um dieses Niveau dermaßen anzureichern, daß sich die sichtbaren Linien wie Resonanzlinien verhalten.

Bei der Verwendung der Resonanzlinie zur Lichterzeugung ist die Anregungswahrscheinlichkeit eine Funktion der kinetischen Energie der Elektronen. Am häufigsten stoßen Elektronen mit etwa der doppelt bis viermal so großen kinetischen Energie wie die Anregungsenergie einer Atomlinie mit den Atomen unelastisch zusammen. Verwendet man Gase mit kleiner Anregungsspannung, so hilft man sich bekanntermaßen gegen die unnötig hohe Geschwindigkeit der Elektronen durch die Zufügung von Edelgasen, die sich durch besonders hohe Anregungsspannungen auszeichnen, wodurch man eine große Zahl elastischer Zusammenstöße erhält.

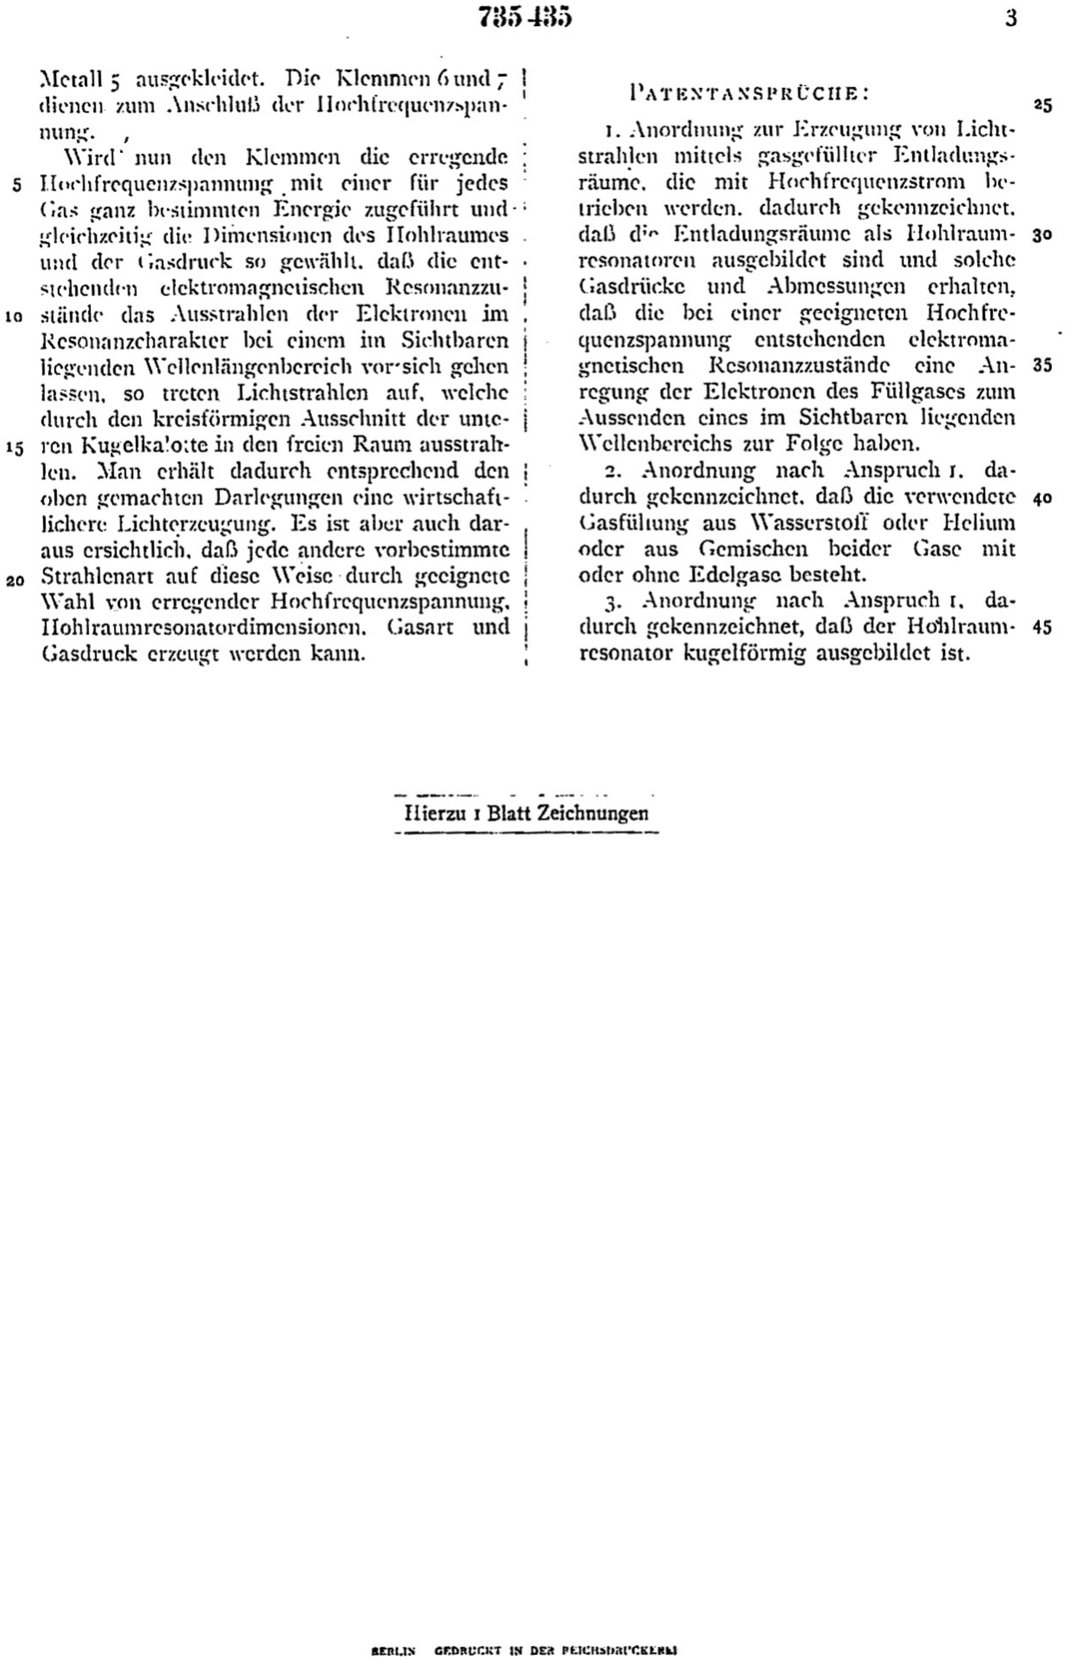
Es ist ferner bekannt, daß das Ausstrahlen von Elektronen nur bei einer ganz bestimmten Einfallsgeschwindigkeit der erregenden Hochfrequenzspannung stattfindet, d. h. dieser Effekt muß einen Resonanzcharakter zeigen, und der Energie- und Impulssatz muß gleichzeitig erfüllt sein. Die innere Energie einer Gesamtheit von Ladungen, wie ein Atom sie darstellt, kann nur periodisch nach den Quantenbedingungen in Strahlung umgesetzt werden. Die Wechselwirkung mit jeder elektrisch geladenen Materie beruht daher darauf, daß das Wellenfeld einer Quantenstrahlung ein elektromagnetisches Feld ist.

Zur Erzeugung geeigneter Resonanzbedingungen ist es notwendig, daß die erregende Hochfrequenzspannung das Magnetfeld im Hohlraumresonator senkrecht durchsetzt, sofern keine starken Feldverzerrungen auftreten.

In der Fig. 1 zeigt das Bild a den bekannten Verlauf der elektrischen Kraftlinien der elektromagnetischen Grundschwingung in einem kugelförmigen Hohlraumresonator, wobei die Durchstoßpunkte der senkrecht zur Zeichenebene gehenden Feldlinien angedeutet sind. Das Bild b zeigt die magnetischen Kraftlinien dieser Hohlkugel. Beide Feldverteilungen sind rotationssymmetrisch um die gezeichnete Achse.

Die Fig. 2 zeigt schematisch ein Anwendungsbeispiel für den grundsätzlichen Aufbau einer erfindungsgemäßen Vorrichtung. In dem kugelförmigen Glasgefäß 1 befindet sich eine Gasfüllung und die ringförmigen Elektroden 2 und 3, die isoliert eingeführt und im Innenraume der Kugel derartig gehalten werden, daß sie im Bereiche des größten Spannungsunterschiedes des elektrischen Feldes zu liegen kommen. Das Innere der Glaskugel ist bis auf einen kreisförmigen Ausschnitt auf der unteren Kalotte 4 metallisiert oder mit

Figure C.80: In 1940, Franz Focke filed a patent application on using resonant excitation to create a population inversion of electron energy levels in a gas, in order to create a light beam with a particular wavelength.



735 435 3

Metall 5 ausgekleidet. Die Klemmen 6 und 7 dienen zum Anschluß der Hochfrequenzspannung.

Wird nun den Klemmen die erregende Hochfrequenzspannung mit einer für jedes Gas ganz bestimmten Energie zugeführt und gleichzeitig die Dimensionen des Hohlraumes und der Gasdruck so gewählt, daß die entstehenden elektromagnetischen Resonanzzustände das Ausstrahlen der Elektronen im Resonanzcharakter bei einem im Sichtbaren liegenden Wellenlängenbereich vor sich gehen lassen, so treten Lichtstrahlen auf, welche durch den kreisförmigen Ausschnitt der unteren Kugelkalotte in den freien Raum ausstrahlen. Man erhält dadurch entsprechend den oben gemachten Darlegungen eine wirtschaftlichere Lichterzeugung. Es ist aber auch daraus ersichtlich, daß jede andere vorbestimmte Strahlenart auf diese Weise durch geeignete Wahl von erregender Hochfrequenzspannung, Hohlraumresonatordimensionen, Gasart und Gasdruck erzeugt werden kann.

PATENTANSPRÜCHE:

1. Anordnung zur Erzeugung von Lichtstrahlen mittels gasgefüllter Entladungsräume, die mit Hochfrequenzstrom betrieben werden, dadurch gekennzeichnet, daß die Entladungsräume als Hohlraumresonatoren ausgebildet sind und solche Gasdrücke und Abmessungen erhalten, daß die bei einer geeigneten Hochfrequenzspannung entstehenden elektromagnetischen Resonanzzustände eine Anregung der Elektronen des Füllgases zum Aussenden eines im Sichtbaren liegenden Wellenbereichs zur Folge haben.

2. Anordnung nach Anspruch 1, dadurch gekennzeichnet, daß die verwendete Gasfüllung aus Wasserstoff oder Helium oder aus Gemischen beider Gase mit oder ohne Edelgase besteht.

3. Anordnung nach Anspruch 1, dadurch gekennzeichnet, daß der Hohlraumresonator kugelförmig ausgebildet ist.

An den
Reichsforschungsrat,
z. Hd. Herrn Professor Dr. W. Gerlach
als Leiter der Fachsparte "Physik"
München 22
Ludwigstrasse 17.–

Betr.: Forschungsauftrag S 4891-5460/1715/3/

Bezug: RFR Brb.-Nr. 2822/45-Ge/Neu.

Angeschlossen füge ich einen Bericht über die bisherigen Ergebnisse meiner Untersuchungen im Rahmen des o.a. Forschungsauftrages bei.

Infolge völliger Inanspruchnahme durch zwei weitere SS-Aufträge seitens des OKH und des OKM bin ich erst jetzt in der Lage gewesen, den Bericht fertigzustellen. Ich bitte deshalb die Verzögerung entschuldigen zu wollen. [...]

Problemstellung.

Es sollen die Atome eines Gases oder Dampfes vom Grundzustand aus in den ersten angeregten /nicht metastabilen/ Zustand gehoben werden, derart, dass dabei höher angeregte Zustände möglischst nicht oder doch nur in verschwindend geringer Zahl vorkommen. Das Gas bezw. der Dampf kann dann lediglich die Resonanzlinie des betr. Atoms emittieren, stellt dann also eine praktisch monochromatische Lichtquelle dar.

Regarding: Research assignment S 4891-5460/1715/3/

Reference: RFR Brb.-Nr. 2822/45-Ge/New.

Attached I include a report on the results of my investigations to date within the framework of the above-mentioned research assignment.

Due to being fully occupied with two other SS projects for the Army and Navy, I have only now been able to complete the report. I therefore apologize for the delay. [...]

Problem statement.

The atoms of a gas or vapor shall be lifted from the ground state into the first excited (not metastable) state, in such a way that higher excited states do not occur at all or only in a negligibly small number. The gas or vapor can then only emit the resonance line of the atom in question, thus representing a practically monochromatic light source.

Bei der Verwendung von Rubidium- oder Cäsiumdampf wäre dann lediglich Strahlung der Wellenlängen 7984 und 7800 A.E. /Rb/ bezw. 8944 und 8521 A.E. /Cs/ zu erwarten, also je zwei diskrete im nahen ultraroten Spektralgebiet gelegene Strahlungsfrequenzen. Dass für jedes Atom zwei Frequenzen auftreten müssen, rührt von der Dublettaufspaltung der P-Terme her.

Um eine solche Lichtquelle von hinreichend grosser Strahlungsintensität zu erhalten, muss die Zahl der im ersten angeregten Zustand befindlichen Atome möglichst gross gemacht werden. Es kommt deshalb nur Anregung durch Elektronenstoss in Frage unter Verwendung einer ergiebigen Glühkathode als Elektronenquelle.

Ferner liegt es nahe, ein Gas bezw. einen Dampf von hoher Dichte zu benutzen, um eine grosse Zahl angeregter Zustände zu erhalten.

Die Verwendung eines hohen Gas- bezw. Dampfdruckes erweist sich aber aus folgenden Gründen als ungeeignet. Durch unvermeidliche Mehrfachstösse werden auch stets höhere Terme der Atome angeregt, und zwar umso mehr, je höher Gasdruck und Stromdichte sind. Ferner steigt mit zunehmender Gasdichte die Wahrscheinlichkeit für das Eintreten von Stössen 2. Art. Diese verursachen wiederum grosse Geschwindigkeiten der stossenden Elektronen und damit eine Vergrösserung der Anregungswahrscheinlichkeit für höhere Atomzustände.–

If rubidium or cesium vapor were used, only radiation of the wavelengths 7984 and 7800 Angstroms (Rb) or 8944 and 8521 Angstroms (Cs) would be expected, i.e. two discrete radiation frequencies in the near infrared spectral region. The fact that two frequencies must occur for each atom is due to the doublet splitting of the P terms.

In order to obtain such a light source of sufficiently high radiation intensity, the number of atoms in the first excited state must be made as large as possible. Therefore, only excitation by electron impact using a high-intensity cathode as electron source is possible.

It also makes sense to use a high density gas or vapor to obtain a large number of excited states.

However, the use of a high gas density or vapor pressure is unsuitable for the following reasons. Due to unavoidable multiple excitations, the higher the gas pressure and current density, the higher the levels of the atoms are excited. Furthermore, with increasing gas density, the probability of the occurrence of collisions increases as the square [of the density]. These in turn cause high velocities of the impinging electrons and thus an increase of the excitation probability for higher atomic states.

In früheren Untersuchungen hat Verf. gezeigt, dass auch in Gasen von sehr kleiner Dichte durch Elektronen kleiner Stromdichte eine sehr starke Anregung möglich ist. Die mittlere freie Weglänge der Elektronen nimmt zwar bei abnehmendem Gasdruck zu und erreicht bereits bei Drucken von der Grössenordnung 0,01 Torr die linearen Dimensionen der gebräuchlichen Entladungsgefässe, also einige Zentimeter. Zwingt man aber durch Anlegen eines äusseren Magnetfeldes die Elektronen auf krummlinige Bahnen /Cykloiden, Kegelschraubenbahnen, u. dgl./, so lässt sich selbst bei sehr niederen Gasdrucken in normalen Entladungsgefässen die Zahl der anregenden Zusammenstösse zwischen Elektronen und Atomen ungeheuer steigern und ein intensives Gasleuchten erreichen. Gleichzeitig ist bei einer solchen Anordnung der weitere Vorteil verbunden, dass bei dem niederen Druck eine strahlungslose Rückkehr der angeregten Atome durch Zusammenstösse mit nichtangeregten Atomen nur selten vorkommt. Untersuchungen dieser Art sind früher mit Stosselektronen grosser Geschwindigkeit /etwa 2.10^3 e-Volt/ durchgeführt worden. Bei diesen Versuchsbedingungen werden auch hochangeregte Atomzustände und auch angeregte Zustände des Atomions in grosser Zahl geschaffen.

Zur möglichst alleinigen Anregung der Resonanzlinie des Atoms muss daher versucht werden, bei niederem Gasdruck mit langsamen Elektronen anzuregen. Für die Fälle der Rubidium- und Cäsiumatoms dürfen die Elektronengeschwindigkeiten dabei nur etwa 2 e-Volt betragen. Dann befindet man sich einmal etwa im Maximum der Anregungsfunktion für den ersten angeregten Zustand, erreicht also die bestmögliche Stossausbeute, zum anderen ist die Wahrscheinlichkeit für die Anregung höherer Atomzustände noch gering.

In earlier investigations the author has shown that even in gases of very low density, a very strong excitation is possible by electrons of low current density. The mean free path length of the electrons increases with decreasing gas pressure and reaches the linear dimensions of the common discharge vessels at pressures of 0.01 Torr, i.e. a few centimeters. If, however, the electrons are forced onto curvilinear orbits (cycloids, conical screw orbits, etc.) by the application of an external magnetic field, the number of stimulating collisions between electrons and atoms can be enormously increased even at very low gas pressures in normal discharge vessels and an intensive gas glow can be achieved. At the same time such an arrangement has the further advantage that at low pressure a return without radiation of the excited atoms due to collisions with non-excited atoms occurs only rarely. Investigations of this kind used to be carried out with high velocity impact electrons (about 2×10^3 electron-Volts). At these experimental conditions both highly excited atomic states and also excited atomic states are created in large numbers.

In order to excite solely the resonance line of the atom as much as possible, an attempt must therefore be made to excite with slow electrons at low gas pressure. For the cases of rubidium and cesium atoms, the electron velocities may only be about 2 electron-Volts. Then one is at the maximum of the excitation function for the first excited state, thus achieving the best possible shock yield, on the other hand the probability for the excitation of higher atomic states is still low.

Als geeignete Entladungsform mit derartig geringen Elektronengeschwindigkeiten kommt allein der Niedervoltbogen in Frage, und zwar die abnormale Bogenform. Es ist daher das erste Ziel der geplanten Untersuchung, einen Niedervoltbogen bei möglichst niederem Gasdruck aufrecht zu erhalten. Ferner ist dann zu untersuchen, ob ein solcher Bogen auch bei Anlegung eines äusseren Magnetfeldes weiterbestehen kann.–

Der Niedervoltbogen ist eine halbselbständige Gasentladung und benutzt als Quelle für die primären Ladungsträger eine Glühkathode. Der Gas- bezw. Dampfdruck beträgt zwischen 5 und 50 Torr.

Beim abnormalen Bogen beträgt die Spannung zwischen Kathode und Anode /Brennspannung/ unter Berücksichtigung der Kontaktpotentiale und der thermischen Anfangsgeschwindigkeit der Glühelektronen nur einen Bruchteil der ersten Anregungsspannung des betr. Atoms. Zunächst erscheint es unmöglich, bei so niederen Brennspannungen überhaupt eine Gasentladung aufrecht erhalten zu können. Genaue Untersuchungen haben jedoch ergeben, dass im Raum zwischen Kathode und Anode, und zwar in Kathodennähe, eine positive Raumladung zustande kommt. Diese bewirkt, dass das Raumpotential zwischen den Elektroden höher liegt als das Anodenpotential und im Maximum einen Wert erreicht, der gleich dem ersten Anregungspotential der betr. Gases oder Dampfes ist. Da nun zur Aufrechterhaltung der Entladung eine ständige Neubildung von positiven Ladungsträgern /Atomionen/ notwendig ist, das Raumpotential jedoch das Ionisierungspotential bei weitem nicht erreicht, so muss eine Trägerneubildung durch stufenweise Ionisierung erfolgen.

Only the low-voltage arc, the unusual arc shape, can be considered as a suitable form of discharge with such low electron speeds. It is therefore the first objective of the planned investigation to maintain a low-voltage arc at the lowest possible gas pressure. Furthermore, it has to be investigated whether such an arc can continue to exist even if an external magnetic field is applied.–

The low-voltage arc is a semi-autonomous gas discharge and uses a hot cathode as the source for the primary charge carriers. The gas or vapor pressure is between 5 and 50 Torr.

With an unusual arc, the voltage between cathode and anode (heating voltage) is only a fraction of the first excitation voltage of the respective atom, taking into account the contact potentials and the initial thermal velocity of the annealing electrons. At first it seems impossible to maintain a gas discharge at such low voltages. However, precise investigations have shown that a positive space charge is generated in the space between cathode and anode, close to the cathode. This causes the space charge potential between the electrodes to be higher than the anode potential and to reach a maximum value equal to the first excitation potential of the gas or vapor concerned. Since a constant new formation of positive charge carriers (atomic ions) is necessary to maintain the discharge, but the space charge potential does not reach the ionization potential by far, a new carrier formation must take place by stepwise ionization.

Im Spektrum des abnormalen Niedervoltbogens treten deshalb ausser den Atomlinien auch stets die Funkenlinien auf. Es ist zunächst die günstigste Versuchsbedingung zu ermitteln, unter welcher die Resonanzlinie des Atoms mit überwiegender Intensität emittiert wird, um dem Ideal einer monochromatischen Lichtquelle möglichst nahe zu kommen.–

Untersuchung des abnormalen Niedervoltbogens bei niederen Drucken.

Als erste Aufgabe wurde die Untersuchung in Angriff genommen mit dem Ziel, bis zu welchen Drucken ein abnormaler Niedervoltbogen überhaupt noch möglich ist. Da alle früheren Untersuchungen am Niedervoltbogen im Druckbereich zwischen 50 und 5 Torr durchgeführt worden sind, ist jetzt bei Drucken unterhalb von 5 Torr gearbeitet worden. Ferner sind zunächst die Untersuchungen nicht an Alkalidämpfen, also z.B. Rubidium oder Cäsium, vorgenommen worden, sondern zunächst einmal an Argon. Dies ist aus folgenden Gründen geschehen. Um die geeignete Form und die beste geometrische Anordnung der Elektroden zu finden, muss das Innere des Entladungsrohres leicht zugänglich sein. Die Elektroden müssen also mit Hilfe von Schliffen ausgewechselt werden können. Bei der Verwendung von Alkalidämpfen ist wegen deren chemischer Aktivität ein solches Entladungsrohr nicht zu benutzen. Ferner muss bei Alkalidämpfen das Entladungsrohr aus alkalifestem Glas hergestellt werden. Dies ist wegen der schwierigen Beschaffung dieser Glassorte zurzeit nicht möglich gewesen. Wenn auch die am Edelgas erhaltenen Ergebnisse nicht in allen Einzelheiten auf Alkalidämpfe übertragen werden können, so werden trotzdem die mit der Edelgas erhaltenen Befunde doch im grossen und ganzen den Weg zeigen, auf welchem die Entwicklung des gewünschten Entladung zu erfolgen hat.

In der abnormalen Entladungsform bei verschiedenen Drucken unterhalb 5 Torr ist zunächst das Raumpotential zwischen Kathode und Anode durch Sondermessungen festgestellt worden.

In the spectrum of the unusually low-voltage arc, therefore, emission lines always occur in addition to atomic lines. The first step is to determine the most favorable experimental condition under which the resonance line of the atom is emitted with predominant intensity in order to come as close as possible to the ideal of a monochromatic light source.–

Investigation of the unusually low voltage arc at low pressure.

The first task was to investigate up to which pressures an unusually low-voltage shock is still possible. Since all previous investigations on the low-voltage arc were carried out in the pressure range between 50 and 5 Torr, work has now been carried out on pressures below 5 Torr. Furthermore, the investigations were not initially carried out on alkali vapours, e.g. rubidium or cesium, but on argon. This was done for the following reasons. In order to find the suitable shape and the best geometrical arrangement of the electrodes, the inside of the discharge tube must be easily accessible. It must therefore be possible to replace the electrodes with the aid of ground joints. When alkali fumes are used, such a discharge tube cannot be used because of their chemical activity. In the case of alkali fumes, the discharge tube must also be made of alkali-resistant glass. This has not been possible at present due to the difficult procurement of this type of glass. Even if the results obtained on the inert gas cannot be transferred in all details to alkali vapours, the findings obtained with the inert gas will nevertheless largely show the way in which the development of the desired discharge must take place.

In the unusual discharge form at various pressures below 5 Torr, the space charge potential between cathode and anode was first determined by special measurements.

Fig. 1 zeigt das benutzte Entladungsgefäss. Als Anode ist ein Nickelblech, als Kathode teils eine Oxydkathode teils eine Wolframwendel benutzt worden.

Die Sonde ist im Raum zwischen Anode und Kathode messbar beweglich angeordnet. Teils ist eine ebene, teils eine Zylindersonde benutzt worden.

Die Figuren 2–5 zeigen die Ergebnisse einigen Sondenmessungen.

Es folgt daraus, dass auch bei Gasdrucken zwischen 6 und 1,5 Torr die Form des abnormalen Niedervoltbogens existiert und dass das Raumpotential über dem Anodenpotential liegt. Das Maximum des Raumpotentials erreicht bei einem Druck von 5,6 Torr gerade das erste Anregungspotential des Argons /11,5 Volt/. Bei abnehmenden Drucken nimmt der Maximalwert des Raumpotentials zu. Die Brennspannung liegt dabei stets unterhalb der ersten Anregungsspannung. Bei Gasdrucken unter 1,5 Torr erreicht die Brennspannung die erste Anregungsspannung, das Potentialmaximum im Entladungsraum erreicht dann die Ionisierungsspannung des Gases /für Argon 15,68 Volt/. Das bedeutet, dass bei diesen Drucken der abnormale Bogen nicht mehr existenzfähig ist. Er ist vielmehr in die Form des normalen Bogens übergegangen. Dies zeigt die Figur 6. Hier—bei einem Druck von 0,5 Torr liegt die Brennspannung zwischen der ersten Anregungs- und der Ionisierungsspannung. Bemerkenswert und bei höheren Gasdrucken noch nicht beobachtet ist weiter die Tatsache, dass trotzdem das Raumpotential höher ist als das Anodenpotential und im Maximum das Ionisierungspotential erreicht oder sogar etwas überschreitet. Die Trägerneubildung erfolgt hier zweifellos in einem Elementarakt durch direkten Stoss und nicht, wie beim abnormalen Bogen, durch stufenweise Ionisierung!

Fig. 1 shows the discharge vessel used. A nickel plate has been used as an anode, and sometimes an oxide cathode and sometimes a tungsten filament as a cathode.

The probe is arranged in the space between anode and cathode so that it is measurably movable. Sometimes a flat probe and sometimes a cylindrical probe has been used.

Figures 2–5 show the results of some probe measurements.

It follows from this that even at gas pressures between 6 and 1.5 Torr the shape of the unusually low-voltage arc exists and that the space charge potential is above the anode potential. The maximum of the space charge potential at a pressure of 5.6 Torr just reaches the first excitation potential of argon (11.5 Volts). With decreasing pressures the maximum value of the space charge potential increases. The heating voltage is always below the first excitation voltage. At gas pressures below 1.5 Torr the heating voltage reaches the first excitation voltage, the potential maximum in the discharge chamber then reaches the ionization voltage of the gas (for argon 15.68 Volts). This means that at these pressures the unusual arc is no longer viable. Rather, it has changed into the form of the normal arc. This is shown in Figure 5. Here, at a pressure of 0.5 Torr, the heating voltage lies between the first excitation voltage and the ionization voltage. Remarkable and not yet observed at higher gas pressures is the fact that the space charge potential is still higher than the anode potential and reaches or even slightly exceeds the ionization potential at the maximum. The formation of the new carrier is undoubtedly an elementary act by direct impact and not, as in an abnormal arc, by gradual ionization!

Die Sondenmessungen ergeben gleichzeitig die Elektronenkonzentration und die Elektronentemperatur an den betr. Orten des Entlandungsraumes. Diese Werte sind in den Figuren 2–5 mit eingetragen.–

Bei allen untersuchten Drucken tritt in der Entlandung des abnormalen Bogens das Funkenspektrum des Argons /das blaue Spektrum/ mit merklicher Intensität neben dem Atomspektrum /rotes Spektrum/ auf. Die Zahl der durch Mehrfachstösse gebildeten Ionen ist also erheblich.–

Bei Anlegung eines äusseren Magnetfeldes in der Weise, dass die Feldlinien denen des elektrischen Feldes zwischen Kathode und Anode parallel verlaufen, müssen die Ladungsträger, besonders die Elektronen, längs ihrer freien Wegstrecken Schraubenbahnen beschreiben. Bei magnetischen Feldstärken zwischen 0 und 150 Oe ist nun ein Instabilwerden der Entladung beobachtet worden, die bisher nur durch Erhöhung der Brennspannung bis mindestens zur Ionisierungsspannung behoben werden kann. Damit ist die Entladung aber in die Form des normalen Niedervoltbogens übergegangen. Ebenso tritt das Funkenspektrum sehr intensiv hervor.–

Zurziet sind daher Versuche im Gang die Brennspannung bei Anlegung eines äusseren Magnetfeldes durch andere Hilfsmittel wieder zu senken. U.a. wird eine gitterförmige Hilfselektrode dicht vor die Glühkathode gesetzt, ähnlich dem Raumladungsgitter der Doppelgitter-Elektronenröhren. Es wird versucht, durch geeignete Aufladung dieser Hilfselektrode die Magnetfeldentladung auch bei sehr niederen Brennspannungen zu stabilisieren. Ergebnisse dieser Versuche stehen noch aus.

The probe measurements give simultaneously the electron concentration and the electron temperature at the respective locations of the mixing area. These values are shown in Figures 2–5.–

At all investigated pressures, in the mixing of the unusual arc, the emission spectrum of the argon (the blue spectrum) occurs with noticeable intensity next to the atomic spectrum (the red spectrum). The number of ions formed by multiple bursts is therefore considerable.–

When an external magnetic field is applied in such a way that the field lines run parallel to those of the electric field between cathode and anode, the charge carriers, especially the electrons, must describe helical paths along their free paths. At magnetic field strengths between 0 and 150 Oersted, an instability of the discharge has now been observed, which so far can only be remedied by increasing the heating voltage to at least the ionization voltage. However, the discharge is now in the form of a normal low-voltage arc. The emission spectrum also emerges very intensely.–

Therefore, attempts are made to reduce the heating voltage by applying an external magnetic field with other aids. Among other things, a grid-shaped auxiliary electrode is placed close to the hot cathode, similar to the space charge grid of the double grid electron tubes. An attempt is made to stabilize the magnetic field discharge even at very low heating voltages by charging this auxiliary electrode appropriately. Results of these experiments are still pending.

Erläuterung zu den Figg. 2–5:

U_B: gemessene Brennspannung
U'_B: korrigierte Brennspannung
U_R: gemessenes Raumpotential
U'_R: korrigiertes Raumpotential
U_k: Kontaktpotential
T_-: Elektronentemperatur
N_-: Elektronenkonzentration.

Als Abszisse ist stets der Abstand zwischen Kathode u. Anode in mm aufgetragen.

Explanation of Figs. 2–5:

U_B: measured heating voltage
U'_B: corrected heating voltage
U_R: measured space charge potential
U'_R: corrected space charge potential
U_k: contact potential
T_-: electron temperature
N_-: electron concentration.

The abscissa is always the distance in mm between cathode and anode.

[This one paper rather miraculously survived. How many other laser-like experiments were there in this group, and in other groups?

Wilhelm von Meyeren's research was in Prague, and funded by and closely tied to the SS, directed energy beam weapons development, and nuclear programs (via Walther Gerlach). Was it the same as, or at least somehow related to, the SS-funded laser work that Wilhelm Voss said was being conducted by Skoda Pilsen (see p. 3157)?

While it is not stated in this one surviving document, it seems quite plausible that von Meyeren might have been planning a photon chain reaction with reflectors once he managed to create a population inversion in the gas atoms, especially since he was reporting to Walther Gerlach, who was also in charge of neutron chain reactions with reflectors, as well as a variety of projects to develop directed energy beam weapons (e.g., pp. 3074–3078). Perhaps other documents can be discovered in order to shed more light on how large this laser-like research program was, how far it progressed, and how much it influenced postwar work in other countries.]

Problemstellung.
Es sollen die Atome eines Gases oder Dampfes vom Grundzustand aus in den ersten angeregten /nicht metastabilen/ Zustand gehoben werden, derart, dass dabei höher angeregte Zustände möglichst nicht oder doch nur in verschwindend geringer Zahl vorkommen. Das Gas bezw. der Dampf kann dann lediglich die Resonanzlinie des betr. Atoms emittieren, stellt dann also eine praktisch monochromatische Lichtquelle dar.

Bei der Verwendung von Rubidium- oder Cäsiumdampf wäre dann lediglich Strahlung der Wellenlängen 7984 und 7800 A.E./Rb/ bezw. 8944 und 8521 A.E./Cs/ zu erwarten, also je zwei diskrete im nahen ultraroten Spektralgebiet gelegene Strahlungsfrequenzen. Dass für jedes Atom zwei Frequenzen auftreten müssen, rührt von der Dublettaufspaltung der P-Terme her.

Um eine solche Lichtquelle von hinreichend grosser Strahlungsintensität zu erhalten, muss die Zahl der im ersten angeregten Zustand befindlichen Atome möglichst gross gemacht werden. Es kommt deshalb nur Anregung durch Elektronenstoss in Frage unter Verwendung einer ergiebigen Glühkathode als Elektronenquelle.

Ferner liegt es nahe, ein Gas bezw. einen Dampf von höher Dichte zu benutzen, um eine grosse Zahl angeregter Zustände zu erhalten.

Die Verwendung eines hohen Gas- bezw. Dampfdruckes erweist sich aber aus folgenden Gründen als ungeeignet. Durch unvermeidliche Mehrfachstösse werden auch stets höhere Terme der Atome angeregt, und zwar umso mehr, je höher Gasdruck und Stromdichte sind. Ferner steigt ~~steigt~~ mit zunehmender Gasdichte die Wahrscheinlichkeit für das Eintreten von Stössen 2.Art. Diese verursachen wiederum grosse Geschwindigkeiten der stossenden Elektronen und damit eine Vergrösserung der Anregungswahrscheinlichkeit für höhere Atomzustände.-

In früheren Untersuchungen hat Verf. gezeigt, dass auch in Gasen von sehr kleiner Dichte durch Elektronen kleiner Stromdichte eine sehr starke Anregung möglich ist. Die mittlere freie Weglänge der Elektronen nimmt zwar bei abnehmendem Gasdruck zu und erreicht bereits bei Drucken von der Grössenordnung 0,01 Torr die linearen Dimensionen der gebräuchlichen Entladungsgefässe, also einige Zentimeter. Zwingt man aber durch Anlegen eines äusseren Magnetfeldes die Elektronen auf krummlinige Bahnen /Cykloiden, Kegelschraubenbahnen, u.dgl./, so lässt sich selbst bei sehr niederen Gasdrucken in normalen Entladungsgefässen die Zahl der anregenden Zusammenstösse zwischen Elektronen und Atomen ungeheuer steigern und ein intensives Gasleuchten erreichen. Gleichzeitig ist bei einer solchen Anordnung der weitere Vorteil verbunden, dass bei dem niederen Druck eine strahlungslose Rückkehr der angeregten Atome durch Zusammenstösse mit ~~neutralen Ato~~ nichtangeregten Atomen nur selten vorkommt. Untersuchungen dieser Art sind früher mit Stosselektronen grosser Geschwindigkeit /etwa 2.10^5 e-Volt/ durchgeführt worden. Bei diesen Versuchsbedingungen werden auch hochangeregte Atomzustände und auch angeregte Zustände des Atomions in grosser Zahl geschaffen.

Zur möglichst alleinigen Anregung der Resonanzlinie des Atoms muss daher versucht werden, bei niederem Gasdruck mit langsamen Elektronen anzuregen. Für die Fälle des Rubidium- und Cäsiumatoms dürfen die Elektronengeschwindigkeiten dabei nur etwa 2 e-Volt

110 2.

betragen. Dann befindet man sich einmal etwa im Maximum der Anregungsfunktion für den ersten angeregten Zustand, erreicht also die bestmögliche Stossausbeute, zum anderen ist die Wahrscheinlichkeit für die Anregung höherer Atomzustände noch gering.

Als geeignete Entladungsform mit derartig geringen Elektronengeschwindigkeiten kommt allein der Niedervoltbogen in Frage, und zwar die abnormale Bogenform. Es ist daher das erste Ziel der geplanten Untersuchung, einen Niedervoltbogen bei möglichst niederem Gasdruck aufrecht zu erhalten. Ferner ist dann zu untersuchen, ob ein solcher Bogen auch bei Anlegung eines äusseren Magnetfeldes weiterbestehen kann.-

Der Niedervoltbogen ist eine halbselbständige Gasentladung und benutzt als Quelle für die primären Ladungsträger eine Glühkathode. Der Gas- bezw. Dampfdruck beträgt zwischen 5 und 5o Torr.

Beim abnormalen Bogen beträgt die Spannung zwischen Kathode und Anode /Brennspannung/ unter Berücksichtigung der Kontaktpotentiale und der thermischen Anfangsgeschwindigkeit der Glühelektronen nur einen Bruchteil der ersten Anregungsspannung des betr. Atoms. Zunächst erscheint es unmöglich, bei so niederen Brennspannungen überhaupt eine Gasentladung aufrecht erhalten zu können. Genaue Untersuchungen haben jedoch ergeben, dass im Raum zwischen Kathode und Anode, und zwar in Kathodennähe, eine positive Raumladung zustande kommt. Diese bewirkt, dass das Raumpotential zwischen den Elektroden höher liegt als das Anodenpotential und im Maximum einen Wert erreicht, der gleich dem ersten Anregungspotential des betr. Gases oder Dampfes ist. Da nun zur Aufrechterhaltung der Entladung eine ständige Neubildung von positiven Ladungsträgern /Atomionen/ notwendig ist, das Raumpotential jedoch das Ionisierungspotential bei weitem nicht erreicht, so muss eine Trägerneubildung durch stufenweise Ionisierung erfolgen.

Im Spektrum des abnormalen Niedervoltbogens treten deshalb ausser den Atomlinien auch stets die Funkenlinien auf. Es ist zunächst die günstigste Versuchsbedingung zu ermitteln, unter welcher die Resonanzlinie des Atoms mit überwiegender Intensität emittiert wird, um dem Ideal einer monochromatischen Lichtquelle möglichst nahe zu kommen.-

Untersuchung des abnormalen Niedervoltbogens bei niederen Drucken.

Als erste Aufgabe wurde die Untersuchung in Angriff genommen mit dem Ziel, bis zu welchen Drucken ein abnormaler Niedervoltbogen überhaupt noch möglich ist. Da alle früheren Untersuchungen am Niedervoltbogen im Druckbereich zwischen 5o und 5 Torr durchgeführt worden sind, ist jetzt bei Drucken unterhalb von 5 Torr gearbeitet worden. Ferner sind zunächst die Untersuchungen nicht an Alkalidämpfen, also z.B. Rubidium oder Cäsium, vorgenommen worden, sondern zunächst einmal an Argon. Dies ist aus folgenden Gründen geschehen. Um die geeignete Form und die beste geometrische Anordnung der Elektroden zu finden, muss das Innere des Entladungsrohres leicht zugänglich sein. Die Elektroden müssen also mit Hilfe von Schliffen ausgewechselt werden können. Bei der Verwendung von Alkalidämpfen ist wegen deren chemischer Aktivität ein solches Entladungsrohr nicht zu benutzen. Ferner muss bei Alkalidämpfen das Entladungsrohr aus alkalifestem Glas hergestellt werden. Dies ist wegen der schwierigen Beschaffung dieser Glassorte zurzeit nicht möglich gewesen. Wenn auch die am Edelgas erhaltenen Ergebnisse nicht in allen Einzelheiten auf Alkalidämpfe übertragen werden können, so werden trotzdem die mit der Edelgas erhaltenen Befunde doch im grossen und ganzen den Weg zeigen, auf welchem die Entwicklung der gewünschten Entladung

Zum Tode von Wilhelm von Meyeren

Am 4. Februar 1983 verstarb in Hannover der emeritierte Professor Dr. phil. Wilhelm von Meyeren, ehemals Direktor des Instituts für Festkörperphysik der Universität Hannover. W. von Meyeren wurde am 26. April 1905 in Berlin geboren, promovierte 1929 bei R. W. Pohl in Göttingen mit einer Arbeit über Alkalihalogenidphosphore und war bis 1935 Assistent am Physikalischen Institut in Karlsruhe bei dem Altmeister der Hochvakuumtechnik Wolfgang Gaede, danach Oberingenieur am Physikalischen Institut der damaligen Technischen Hochschule Hannover. Dort habilitierte er sich 1937 und wurde 1941 auf den Lehrstuhl für Experimentalphysik der damaligen Deutschen Karls-Universität in Prag berufen. 1945 unter unmenschlichen Umständen mit seiner Ehefrau Hedi von Meyeren vertrieben, gelangte er nach schweren Jahren als Professor wieder nach Hannover auf einen Lehrstuhl für Atomphysik und baute dort das 1962 neugegründete Institut für Experimentalphysik B, das jetzige Institut für Festkorperphysik, auf.

On the death of Wilhelm von Meyeren

On 4 February 1983 in Hanover, the emeritus professor Dr. phil. Wilhelm von Meyeren, former director of the Institute of Solid State Physics at the University of Hanover, died. W. von Meyeren was born on 26 April 1905 in Berlin, received his doctorate in 1929 from R. W. Pohl in Göttingen with a thesis on alkali halide phosphors and was assistant at the Physikalisches Institut in Karlsruhe until 1935 to the old master of high vacuum technology Wolfgang Gaede, then chief engineer at the Physikalisches Institut of the then Technische Hochschule Hannover. There he habilitated in 1937 and in 1941 was appointed to the Chair of Experimental Physics at the then German Charles University in Prague. In 1945 he was expelled under terrible circumstances with his wife Hedi von Meyeren. After many difficult years as a professor, he returned to Hanover to take up a chair in atomic physics, where he built up the Institute for Experimental Physics B, newly founded in 1962, now the Institute of Solid State Physics.

Seine wissenschaftlichen Arbeiten behinhalten—ausgehend von den Anfängen der Festkörperphysik der Pohlschen Schule—die Hochvakuumphysik (Gasaufzehrung), die Spektroskopie verdünnter Gase und mündeten schließlich in der modernen Halbleiterphysik. In der Zeit zwischen seiner Lehrtätigkeit in Prag und in Hannover erscheint W. von Meyeren als Mitautor mehrerer Sammelwerke wie Fiat-Review, Angerer-Ebert, Technische Kunstgriffe, des Gmelin-Handbuchs, sowie des Physikalischen Wörterbuches von Westphal.

W. von Meyeren war mit Stolz ein Physiker alter Schule und darüber hinaus ein guter Pädagoge, der seine Pflichten als Hochschullehrer sehr ernst nahm. Lange Jahre galt seine Aufmerksamkeit der Allround-Ausbildung der Physiker in einer Art höherer Experimentalphysik ebenso wie einem Einführungsseminar für Studienanfänger mit ihrer so erschreckend differierenden Schulvorbildung. Ein besonderes Anliegen war ihm auch die Einführung der Ingenieur-Studenten in die sich rasant entwickelnde Festkörperphysik, insbesondere die Metallphysik.

Kollegen und auch seine Schüler, denen er ein väterlicher Freund war, wissen von seiner steten Hilfsbereitschaft zu berichten. Manche seiner zahlreichen Freunde und Bekannten erinnern sich gern an sein gastfreundliches Haus.

His scientific work includes—originating from the beginnings of solid-state physics of the Pohl school—high vacuum physics (gas consumption), the spectroscopy of diluted gases, and finally modern semiconductor physics. In the period between his teaching activities in Prague and Hanover, W. von Meyeren co-authored several anthologies such as *FIAT Review*, *Angerer-Ebert*, *Technical Methods*, the *Gmelin Handbook*, and the *Physics Dictionary* of Westphal.

W. von Meyeren was proud to be an old school physicist and a good teacher who took his duties as a university teacher very seriously. For many years his attention was focused on the all-round training of physicists in a kind of higher experimental physics as well as on an introductory seminar for first-year students with their so frighteningly different prior school education. He was also particularly interested in the introduction of engineering students to the rapidly developing field of solid state physics, especially metal physics.

Colleagues and also his students, to whom he was a fatherly friend, know about and describe his constant helpfulness. Some of his numerous friends and acquaintances fondly remember his hospitable house.

Tom Agoston. 1985. *Blunder! How the U.S. Gave Away Nazi Supersecrets to Russia.* New York: Dodd, Mead. pp. 12-13.

By quirk of fate, the careers of Kammler and Voss overlapped at Skoda, where they jointly set up and operated what was generally regarded by insiders as the Reich's most advanced high-technology military research center. Working as a totally independent undercover operation for the SS, the center was under the special auspices of Hitler and Himmler. [...] In so doing the SS group was to go beyond the first generation of secret weapons.

Its purpose was to pave the way for building nuclear-powered aircraft, working on the application of nuclear energy for propelling missiles and aircraft; laser beams, then still referred to as "death rays"; a variety of homing rockets, and to seek other potential areas for high-technology breakthrough. In modern high-tech jargon, the operation would probably be referred to as an "SS research think tank." Some work on second-generation secret weapons, including the application of nuclear propulsion for aircraft and missiles, was already well advanced.

It was far from a mad Nazi scientist's dream of getting to the end of the nuclear rainbow. The field had been pioneered by Dr. Wernher von Braun, designer of the V-2, in the early 1930s. In addition, it was recently disclosed that one of the first top German engineers cleared for urgent work for the U.S. Air Force in 1945 was Dr. Franz Josef Neugebauer, a specialist in thermal systems for aircraft nuclear propulsion. In 1958 the United States launched Project Orion to probe the applicability of nuclear propulsion for aircraft, employing some Czech scientists. The project was continued until 1965 and then was turned over to the U.S. Air Force, plans for its application for the civilian space programs having been dropped.

The SS research operation at Skoda had been set up without the knowledge of Goering, Speer, or the German research centers. The builders of the V-1 and V-2 were likewise kept out of the picture. The undercover SS research operation fitted in with Himmler's dream that, as the Rheingold of the Nibelung's, if shaped into a ring, would give its possessor mastery of the world, so would the SS team give the Greater Reich mastery of much of the world.

A study of intelligence reports shows that blueprints, drawings, calculations, and other relevant documentation or materials were protected by a triple ring of SS counter-intelligence specialists Himmler had assigned to Pilsen to prevent security leaks and sabotage in the research divisions and the plant in general. The SS team was internally referred to as the Kammler Group. Taking a leaf from the armament ministry name for the special section Kammler headed there to iron out aircraft production bottlenecks, they were called the Kammler stab or Kammler "staff."

Heinz Schaeffer. 1952. *U-Boat 977.* p. 187–188.

It took twenty-four hours to reach Berlin—we had air-raid warnings at regular intervals and took cover underneath the train till it could go on again. Next to me sat an S.S. officer who, in spite of my flatly contradicting him, simply would not stop talking about decisive new secret weapons. I was fed up with secret weapons by now for I knew perfectly well from my own experience that if all the blueprints were there so were the air-raids on our factories. "Well, of course, you aren't really in a position to judge," he said, but he was, naturally, because he was working at some S.S. H.Q. or other and was out watching the tests every day. If I would only come and look him up I would see something that would make me sit up.

When I got to Berlin I really did look him up, and after I had waited at the H.Q. entrance for some time my new acquaintance appeared and started showing me round. Everybody there was certain we were going to win, with a conviction I'd never seen the like of even after the fall of France. Among the fantastic contrivances of which I was shown photographs was one called a death ray which my friend wanted me to come back and see in action next day.

But I wasn't wasting any more time. I wanted to see my mother, for it was obvious the Russians were advancing on Berlin and that the last battle was going to be fought there. The city was being transformed into a fortress, with tram-cars overturned and barricades going up everywhere. I wanted to get my mother away, but she said she meant to stay in Berlin at all costs; she would manage the Russians all right, she said. And so she did.

Herbert A. Werner. 1969. *Iron Coffins: A Personal Account of the German U-Boat Battles of World War II.* p. 228.

I was thinking about our much-discussed new weapons, including death rays and atom bombs, which were now in the development stage...

United States Air Force Oral History Program: Interview #K239.0512-724 of Lt General Donald L. Putt by Dr. James C. Hasdorff. 1–3 April 1974. [AFHRA 43826 electronic version pp. 1009–1010]

H[asdorff]: Why was there such a slow application of laser technology in the US? I understand we were dabbling with it during World War II.

P[utt]: Well, I'm not an expert on lasers, but it's my understanding that the phenomenon was discovered which gave one the capability of having coherent beams. But for a long time nobody could figure out what it was good for. It was one of these scientific curiosities, and it just took a long time to find the application. Now whether we proceeded as fast as could have been done if there were no budgetary restraints or anything like that, I guess I'm not familiar enough with the field to know that. But in the early days I know that was one of the problems; we said, "Here's something that's very interesting, but what can we use it for?" And now we're finding all kinds of uses for it, of course, in civil work, et cetera.

[In the United States, theoretical design work on lasers did not begin until the mid–late 1950s, and the first working laser was not built until 1960, at least according to official histories.

In the above question and answer, were Hasdorff and Putt simply confused, or were they referring to actual earlier work on lasers?

If they were referring to earlier work that indeed occurred, was it wartime work in the United States, perhaps by or based on the earlier research of German-speaking immigrant scientists such as Rudolf Ladenburg or James Franck?

Alternatively, since Putt was deeply involved in rounding up German-speaking scientists and information from Europe at the end of the war and putting them to use in the postwar United States, were Hasdorff and/or Putt referring to wartime German work on lasers (perhaps such as that of Wilhelm von Meyeren) that was brought to the United States after the war?]

Michel Bar-Zohar. 1967. *The Hunt for the German Scientists.* pp. 140, 207.

There was also a vague report on the mysterious Zimmermann—the man believed to have invented the 'death ray' and even to have used it effectively against the Russians in the Carpathians on 30 August 1944. The report said that he had been captured and taken to Russia just before the end of the war. [...]

Dr. Hans Ehrhardt, who was expelled from Switzerland for having experimented with a mysterious green death ray...

[Can any information be found regarding Zimmermann and his alleged directed energy weapon?

Hans Ehrhardt's laser-like work is discussed on the following pages. If Bar-Zohar's information is accurate, Ehrhardt's beam was green. That suggests that it may have been an argon gas laser or something similar. Could Erhardt's work have been directly related to von Meyeren's wartime work on laser-like light emission from electrically excited argon gas?]

Schweiz/Todesstrahlen: Schnee geschmolzen. *Der Spiegel.* 24 July 1963 p. 58. [https://www.spiegel.de/spiegel/print/d-46171297.html]

24.07.1963
SCHWEIZ / TODESSTRAHLEN
Schnee geschmolzen

Ungewöhnliche Order lief Anfang vergangener Woche bei eidgenössischen Polizeidienststellen ein:

Die Gesetzeshüter wurden angehalten, nach einem Mann zu fahnden—freilich nicht, um ihn zu verhaften. Vielmehr sollte sichergestellt werden, daß der Gesuchte wirklich verschwunden ist und damit die eidgenössische Bürokratie von einer Blamage befreit hat.

Der Gesuchte nennt sich Dr. Hans Ehrhardt und hieß früher Hans Engelke. Als Amateur-Physiker war er—nach eigenen Angaben zusammen mit Wernher von Braun—in der Rüstungsindustrie des Dritten Reiches beschäftigt gewesen.

Dabei erfand er eine Wunderwaffe: Engelke wollte in den von feindlichen Bomberstaffeln durchflogenen Luftschichten dichte Wolken feinster Kohlenstoffpartikel verteilen. Mittels einer Zündrakete sollte beim Herannahen von Feindflugzeugen ein Schlagwetter in der Atmosphäre erzeugt werden. Beim ersten und einzigen Versuch mit seiner Wunderwaffe, so fabulierte Engelke-Ehrhardt, seien im April 1945 gleich 36 Bomber auf einen Schlag vom Himmel geholt worden.

Nach Krieg und alliierter Internierung wandte sich Autodidakt Ehrhardt einem anderen physikalischen Phänomen zu: Er begann Versuche mit Strahlen, die laut eigener Aussage “im Frieden Kranke heilen und im Kriege Feinde töten” sollten.

24 July 1963
SWITZERLAND / DEATH RAYS
Melted snow

An unusual order arrived at the beginning of last week at the national police station:

The law enforcers were spared from having to find and arrest a man. Rather they were to make sure that the wanted man had really disappeared and thus the national bureaucracy had been saved from embarrassment.

The person for whom they searched called himself Dr. Hans Ehrhardt and earlier Hans Engelke. As an amateur physicist he had been—by his own account together with Wernher von Braun—employed in the armament industry of the Third Reich.

Back then he invented a miracle weapon: Engelke wanted to distribute dense clouds of fine carbon particles in the air layers through which enemy bombers flew. By means of an igniting rocket, an explosion in the atmosphere should be generated at the approach of enemy aircraft. The first and only attempt with his silver bullet, claimed Engelke-Ehrhardt, had knocked as many as 36 bombers from the sky with one explosion in April 1945.

After the war and Allied internment, the autodidact Ehrhardt turned to another physical phenomenon: he began experiments with beams that should in his words “heal sick people in peacetime and kill enemies in wartime.”

Aus einer Gasplasma-Quelle gedachte der Erfinder mit großen Hohlspiegeln einen gebundelten ultravioletten Lichtstrahl herzustellen. Dieser Todesstrahl sollte einerseits 30 000 Kilometer weit wirken und eine “ungeheure Zerstörungskraft” (so Ehrhardt) entwickeln, andererseits aber Krebskranke von ihren Leiden befreien, “ohne daß Knoten oder Kapselungen zurückbleiben”.

In der Bundesrepublik gelang es dem modernen Cagliostro nicht, seine Ideen zu verkaufen, obgleich Deutschland stets ein dankbares Feld für Wundermänner war: Nach dem Ersten Weltkrieg gelang es dem geisteskranken Österreichischen Landbriefträger Karl Schappeller, Ex-Kaiser Wilhelm II. große Summen für einen Plan zu entlocken, Deutschland “durch die Nutzung ungeheurer Energien aus dem kosmischen Raum zur ersten Weltmacht zu machen”. Zur selben Zeit begeisterte ein Betrüger namens Franz Tausend den General Ludendorff mit seiner angeblichen Fähigkeit, aus Eisen und Blei Gold zu gewinnen.

Dem Strahlenmagier Ehrhardt glückte es hingegen Anfang 1961, die Kriegstechnische Abteilung (KTA) des Eidgenössischen Militärdepartements in Bern für seine phantastischen Projekte zu interessieren.

Die schweizerischen Landesverteidiger luden Ehrhardt am 24. Februar 1961 zu einer Besprechung ein und forderten ihn auf, schriftliche Unterlagen beizubringen. Eine Prüfung des Ehrhardt -Exposes durch Züricher TH-Professoren veranlaßte freilich die KTA am 31. Mai 1961 dazu, auf eine weitere Zusammenarbeit mit Ehrhardt zu verzichten.

From a gas plasma source, the inventor intended to use large concave mirrors to produce a narrow ultraviolet light beam. This death ray should in one case have a range of 30,000 kilometers and (according to Ehrhardt) develop a “monstrous destructive power,” but in the other case free cancer patients from their suffering “without a node or capsule remaining.”

In West Germany this modern Cagliostro was unable to sell his ideas, even though Germany has always been a grateful field for miracle workers: After World War I the insane Austrian postman Karl Schappeller succeeded in obtaining large sums from ex-Kaiser Wilhelm II for a plan to make Germany “the greatest power in the world through the use of monstrous energy from cosmic space.” At the same time an impostor named Franz Tausend interested General Ludendorff with his alleged ability to turn iron and lead into gold.

At the beginning of 1961, however, the ray magician Ehrhardt succeeded in interesting the War Technical Department (KTA) of the Federal Military Department in Bern in his fantastic projects.

The Swiss defense officials invited Ehrhardt to a meeting on 24 February 1961 and asked him to bring written proposals. An examination of Ehrhardt’s documents by Zurich Technical University professors prompted the KTA on 31 May 1961 to refrain from further cooperation with Ehrhardt.

Interessiert an den Künsten des deutschen Physikers blieb indes weiterhin ein Beamter der KTA: Adjunkt Eugen Burkhard, Chef der Rüstungszentrale der Kriegstechnischen Abteilung, erhoffte sich von Ehrhardts Ideen Entdecker-Ruhm und förderte den Deutschen in eigener Regie.

Als KTA-Beamten fiel es Burkhard leicht, dem Forscher Aufenthaltsbewilligung und Wohnung zu verschaffen. Im August 1961 siedelte sich der Waffenrevolutionär mit Gattin Ilse und vier Sprößlingen am Sarner See im Kanton Obwalden an.

Rückendeckung für die folgenden Versuche wurde Ehrhardt durch die “Bewilligung 2524” der KTA zuteil, in der dem Physiker gegen Entrichtung von 50 Franken Gebühr und 80 Rappen Porto routinegemäß erlaubt wird, “Prototypen zu Geschossen ohne Patronenhülsen bis zum Kaliber 30 mm herzustellen”.

In Wahrheit experimentierte der Sarner Neubürger aber nicht mit 30-mm-Geschossen, sondern mit “Todesstrahlen”. Mit diesen Produkten seines Erfindergeistes schmolz Ehrhardt im letzten Frühjahr—so erzählte er der “Deutschen National-Zeitung”—auf eine Entfernung von zwölf Kilometern binnen Sekunden anderthalb Meter hohen Gletscherschnee. Applaudierte die DNZ: “Erfinder Dr. Ehrhardt, Herr über Tod und Leben.”

Ungemach näherte sich dem Herrn über Tod und Leben freilich, als Anfang Juni ein Photo erschien, das den Ehrhardtschen Todesstrahl als drohend himmelwärts gerichteten Finger über dem Sarner See zeigte.

Interest in the creations of the German physicist remained, however, for one official of the KTA: Adjunct Eugen Burkhard, head of the Armament Center of the War Technical Department, hoped that Ehrhardt’s ideas were pioneering and supported the German on his own.

As a KTA official, it was easy for Burkhard to obtain a residence permit and housing for the researcher. In August 1961, the weapon revolutionizer and his wife Ilse and four offspring settled on Sarner Lake in the canton Obwalden.

Ehrhardt received support for the ensuing experiments through the KTA “Permit 2524,” by which the physicist routinely accepted payments of 50 francs fee and 80 cents postage “to produce prototype projectiles without shell casings up to 30 mm caliber.”

In truth, the new Sarner resident experimented not with 30-mm projectiles, but with “death rays.” With these products of his ingenuity, last spring Ehrhardt melted—so he told the *German National Newspaper* (DNZ)—one and a half meters of glacier snow within seconds at a distance of twelve kilometers. The DNZ applauded: ”inventor Dr. Ehrhardt, master of life and death.”

Trouble approached the master of life and death, as at the beginning of June, a photo was published that showed Ehrhardt’s death ray as a threatening finger pointed skyward over the Sarner Lake.

Die eidgenössische Presse, von der schockierten Fremdenindustrie alarmiert, überhäufte die nichtsahnende Kriegstechnische Abteilung mit Vorwürfen wegen dieser “lebensgefährlichen Experimente”, während die Sarner Gastwirte Schadenersatz für die Gäste forderten, die wegen der Todesstrahlen fernbleiben würden.

Das Militärdepartement ließ eilends verlauten, Ehrhardt habe “keinen Rappen” schweizerischer Steuergelder für seine Experimente erhalten. Zugleich interessierte sich die eidgenössische Sicherheits- und Fremdenpolizei eingehend für den Deutschen.

Dabei ergab sich laut Polizeibericht, daß Ehrhardt “über wesentliche Punkte seiner Person und seines Vorlebens unwahre Angaben gemacht hatte, so über seine Tätigkeit in der DDR”.

Da witterten die Behörden die Chance, sich des peinlichen Gastes zu entledigen: Am 4. Juni eröffnete die Fremdenpolizei Obwalden dem Ehrhardt, daß sein Aufenthalt bis zum 15. Juli 1963 befristet sei.

Zwei Tage vor Ablauf der Frist, in der Nacht vom 13. auf den 14. Juli, verschwand Ehrhardt aus seinem Sarner Domizil, ohne sich abzumelden oder eine Adresse zu hinterlassen.

Mit seinem allzu stillen Abschied wurde Ehrhardt freilich gezwungen, vorerst auch auf die Verwirklichung eines Planes zu verzichten, den er in der Ende 1962 herausgegebenen Schrift “Der neue Weg” publik gemacht hatte: die Nutzbarmachung eines von ihm erdachten Perpetuum mobile.

Erfinder Ehrhardt

“Ungeheure Zerstörungskraft... über 30 000 Kilometer”: Ehrhardt-Strahl am Sarner See

The national press, alarmed by this shocking outsider industry, showered the unsuspecting War Technical Department with allegations of these “perilous experiments,” while the Sarner innkeepers demanded compensation for losing guests who would stay away because of the death rays.

The Military Department hastily announced that Ehrhardt had received “not a cent” of Swiss tax money for his experiments. At the same time, the national security and immigration police became interested in details about the German.

According to the police report, it was found that Ehrhardt “had given untrue information regarding significant points about himself and his prior life, as well as his activities in East Germany.”

Here the authorities sensed the chance to get rid of the embarrassing guest: On June 4, the Obwalden immigration police disclosed to Ehrhardt that his stay must end by 15 July 1963.

Two days before the deadline, in the night from 13 to 14 July, Ehrhardt disappeared from his Sarner home without checking out or leaving a forwarding address.

With his all too silent departure, Ehrhardt was indeed forced to abandon the realization of a plan, which he had made public in his writing “The New Way” published at the end of 1962: harnessing a perpetual energy source he had devised.

Inventor Ehrhard [Fig. C.93]

“Monstrous destructive power... over 30,000 kilometers”: Ehrhardt’s ray over Sarner Lake [Fig. C.95]

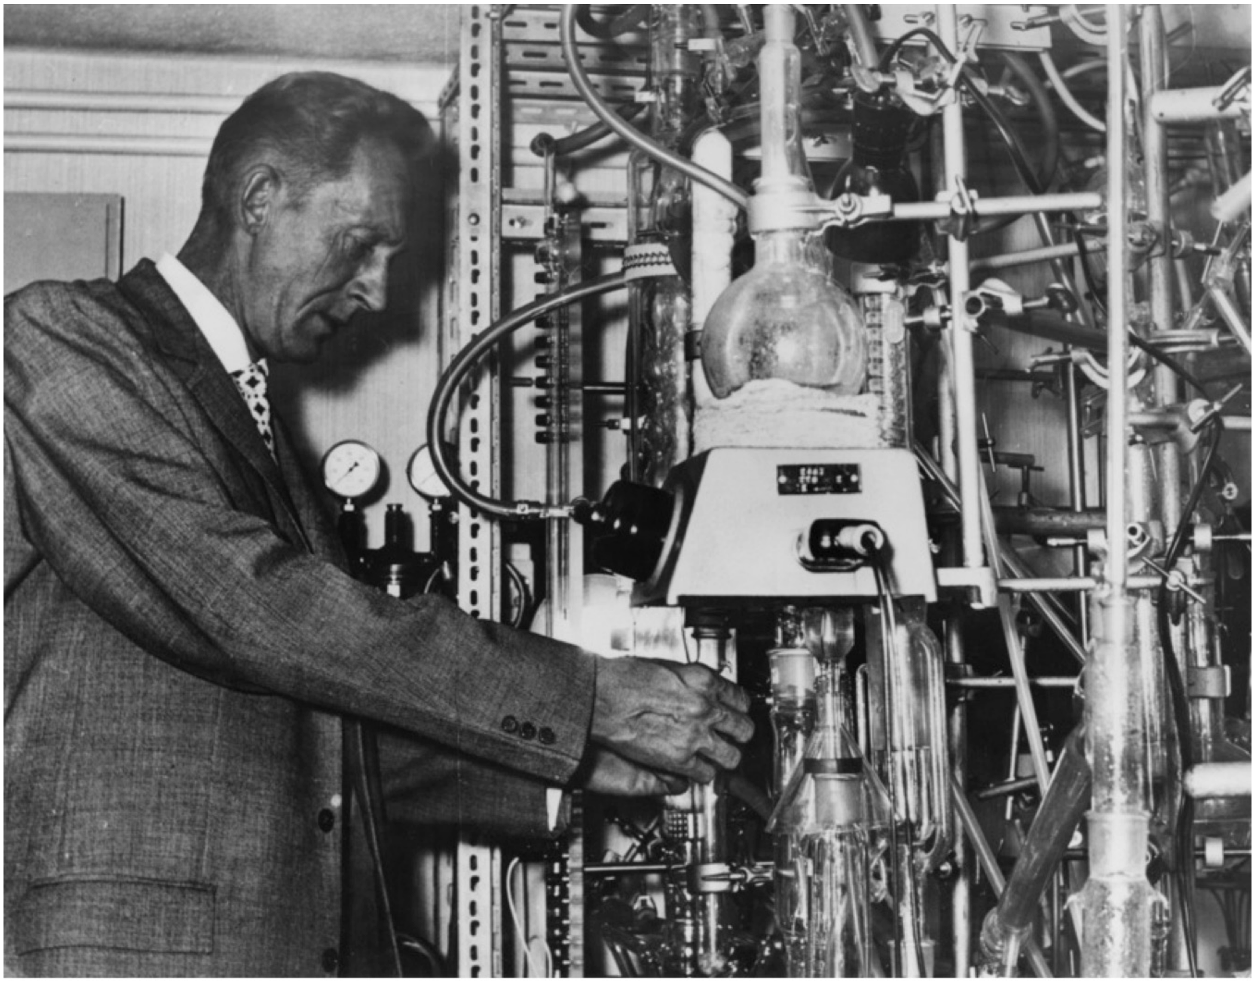

Figure C.93: Hans Ehrhardt/Engelke in his 1961–1963 Swiss lab.

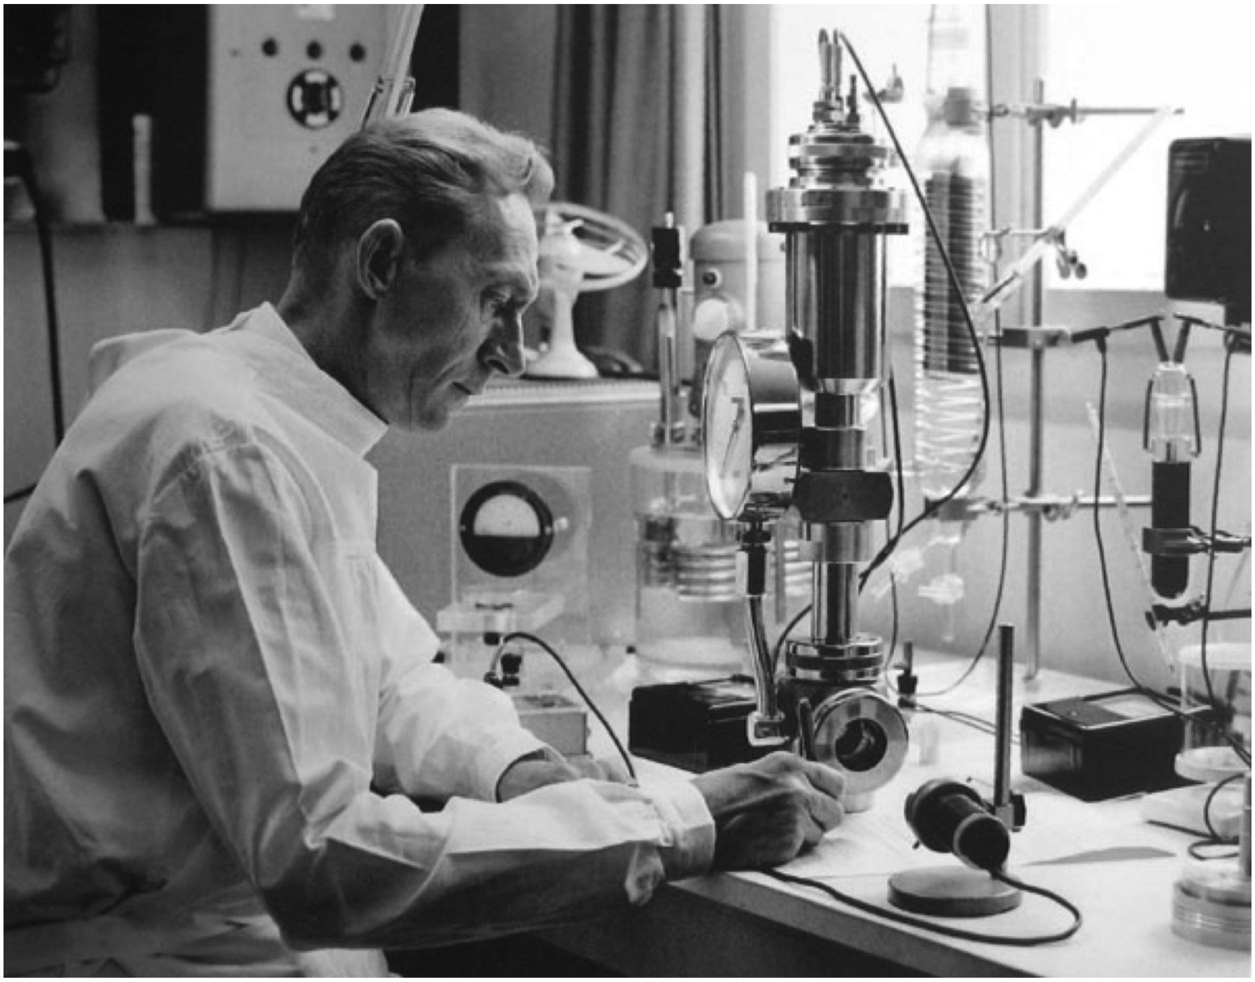

Figure C.94: Hans Ehrhardt/Engelke in his 1961–1963 Swiss lab, working on a device that appears to resemble a gas laser.

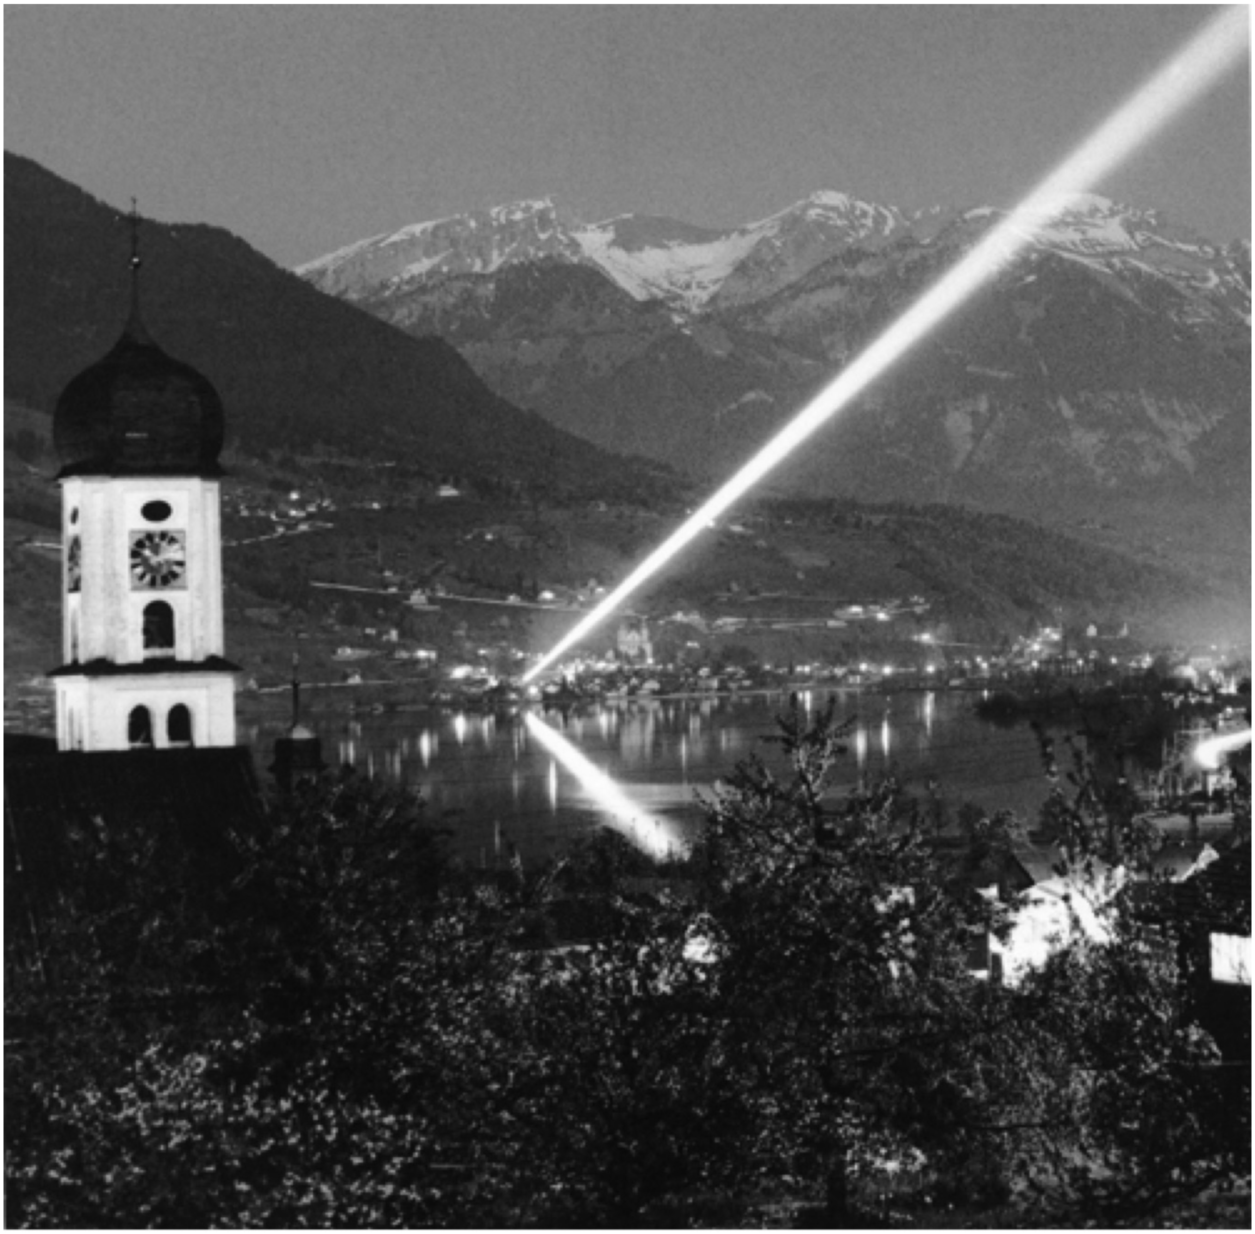

Figure C.95: Demonstration of Hans Ehrhardt's/Engelke's laser-like beam over the Swiss Sarner See. The clock hands indicate 10:10, which could be a.m. or p.m. Based on the lights visible in the buildings and reflected in the water, this photo was taken at night, so 10:10 p.m. The brightness of the sky suggests a long exposure and/or moonlit night. Even just the small fraction of light scattered by dust particles out of the beam toward the camera is clearly much brighter than the building lights, so the light within the beam would have been quite intense. Most of the apparent expansion of the beam is due to the perspective of the beam coming from the distance toward the camera; the beam is remarkably well collimated. Although the photo is black and white, observers reported that the beam was green.

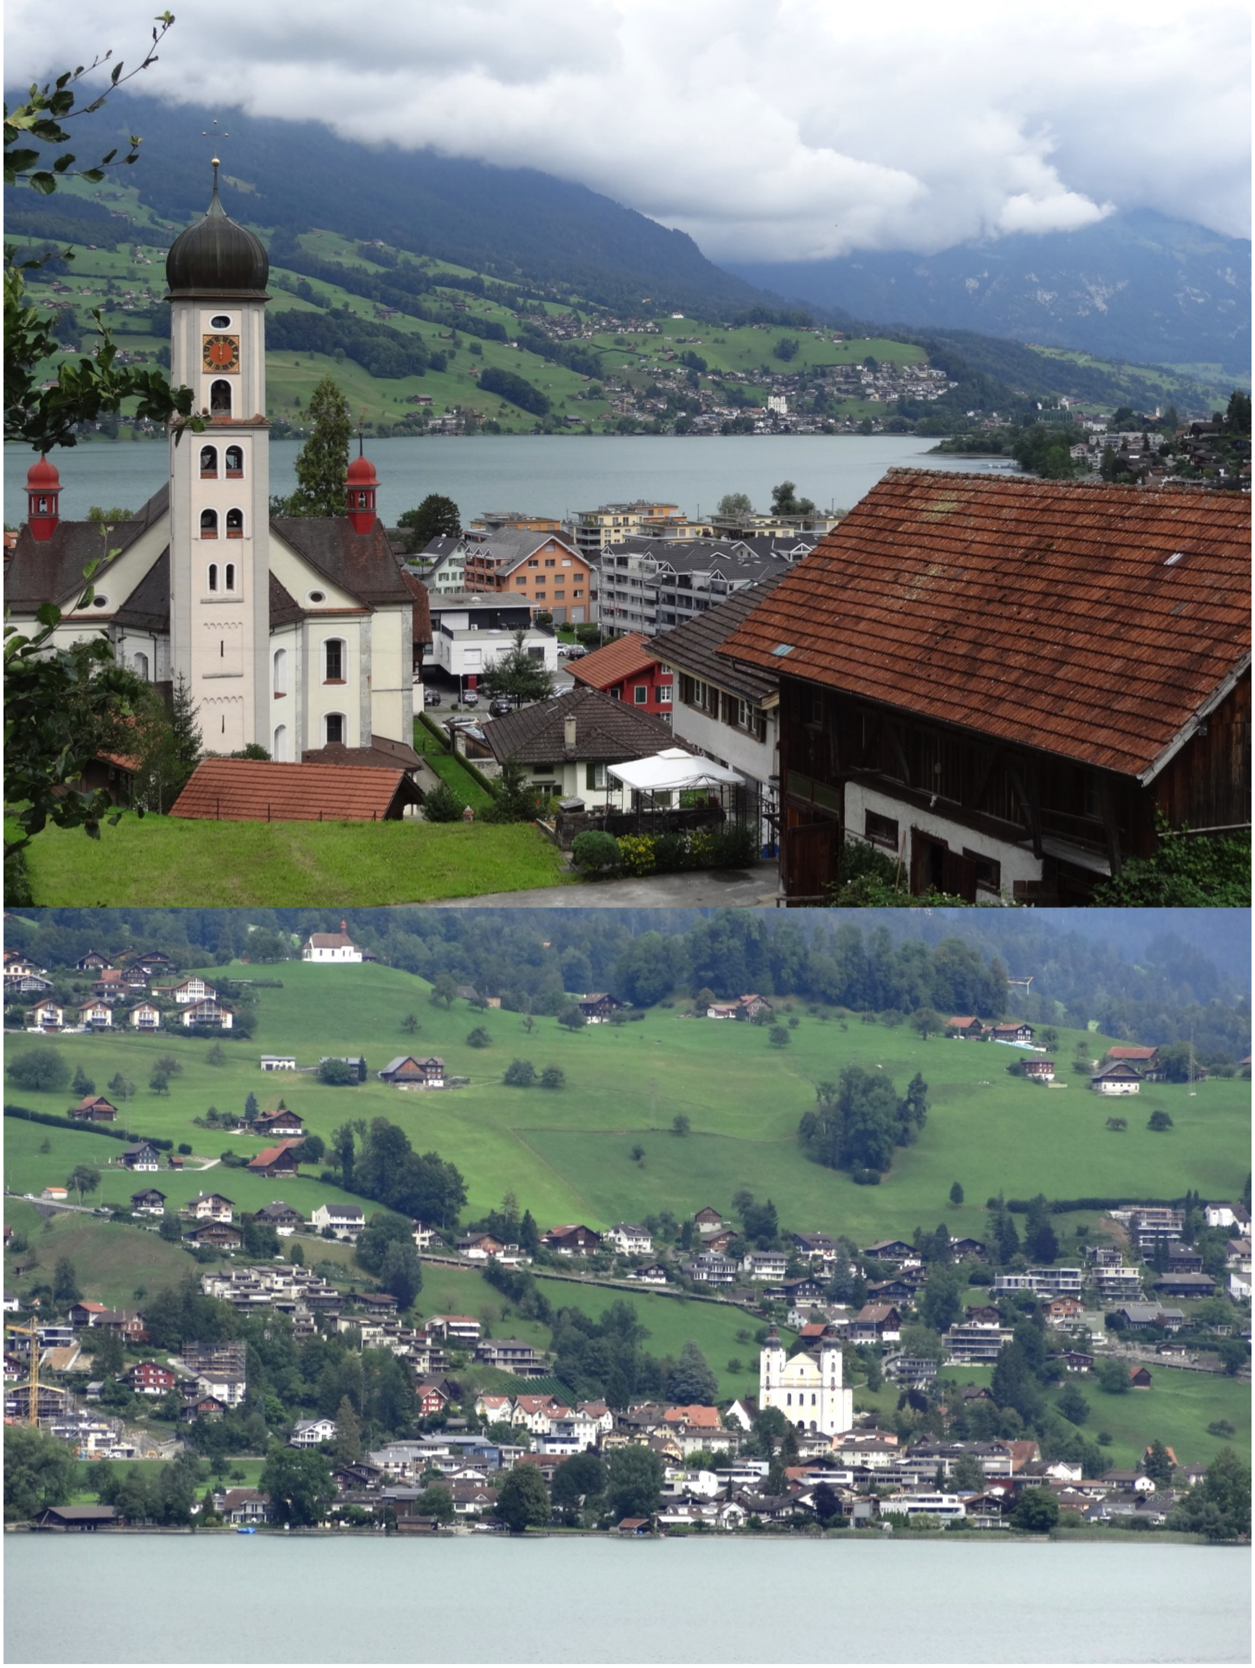

Figure C.96: The view now from a hill behind the Pfarr- und Wallfahrtskirche Sachseln church in Sachseln looking toward the north, across the Sarner See toward the Pfarrkirche St. Peter und Paul church in Sarnen. Hans Ehrhardt's/Engelke's laser-like beam was apparently fired from the vicinity of a waterfront house or hotel somewhat to the left of the Sarnen church.

"Todesstrahlen" über dem Sarner See: Über den "deutschen Physiker" Hans Ehrhardt, der in der Schweiz beinahe das Perpetuum mobile erfunden hat. *Physikalische Blätter* 19:11:511–516. November 1963.
[**https://onlinelibrary.wiley.com/doi/abs/10.1002/phbl.19630191104**]

[...] Mit dem Doktor ist es nichts, mit dem Studium dürfte es auch nichts sein; jedenfalls ist Hans Ehrhardt kein Physiker in unserem Sinn, d.h. nicht ein Mann, der eine wissenschaftliche Schulung in der Physik durchlaufen und sein Studium mit der Prüfung an einer Universität oder Hochschule abgeschlossen hat. Ehrhardt nennt sich Ingenieur, gelegentlich aber auch Physiker; er dürfte Autodidakt sein, der schon vor 1945 sonderbaren Ideen nachging, wie der einer neuartigen Flugabwehrwaffe mit gebündelten Ultraviolettstrahlen, deren Wirksamkeit er auf mehrere 10000 km Distanz glaubte garantieren zu können. [...]

Das Gutachten aus dem Laboratorium für Festkörperphysik der ETH trifft den Nagel auf den Kopf. In dem uns von Prof. Dr. Gärnicher freundlicherweise zugestellten Schriftstück, das übrigens nur durch Indiskretion in die Öffentlichkeit gelangte und das von einem Doktoranden des Laboratoriums (nicht des Phys. Inst.) erstattet worden ist, heisst es: "Die untersuchte Arbeit ist wissenschaftlich wertlos. Der Verfasser stellt darin Behauptungen auf, welche darin gipfeln, er habe das Perpetuum mobile erster Art erfunden... Das konfuse physikalische Weltbild des Verfassers lässt sich etwa folgendermassen zusammenfassen: Raum und Materie sind durchsetzt von Wolken freier Elektronen in unterschiedlicher Dichte. Diese freien Elektronen sind in dauernder ungeordneter Bewegung, verursacht durch "Urkräfte der Materie". Nun braucht man nur diese Bewegung zu ordnen, was an Halbleiter- und Grenzschichten geschehen soll, um einen dauernden elektrischen Stromfluss zu erhalten..."

[...] There is nothing to his doctorate; there should also be nothing to his education; in any case Hans Ehrhardt is not a physicist in our sense, i.e. not a man, who went through a scientific training in physics and finished his study with the examination at a university or college. Ehrhardt calls himself an engineer, but occasionally also a physicist; he is probably self-taught, who already before 1945 pursued strange ideas, such as that of a novel anti-aircraft weapon with bundled ultraviolet rays, the effectiveness of which he believed he could guarantee over a distance of several 10000 km. [...]

The report from the Laboratory for Solid State Physics at ETH Zurich hits the nail on the head. In the document kindly sent to us by Prof. Dr. Gärnicher, which, by the way, only came into the public eye through indiscretion and which was reimbursed by a doctoral student of the laboratory (not of the Phys. Inst.), it says: "The work examined is scientifically worthless. The author makes claims in it, which culminate in the fact that he invented perpetual motion of the first kind... The confused physical world view of the author can be summarized as follows: Space and matter are interspersed with clouds of free electrons of different density. These free electrons are in constant disordered motion, caused by 'forces of matter.' Now one only needs to order this movement, what should happen at semiconductor and boundary layers, in order to receive a continuous electric current flow..."

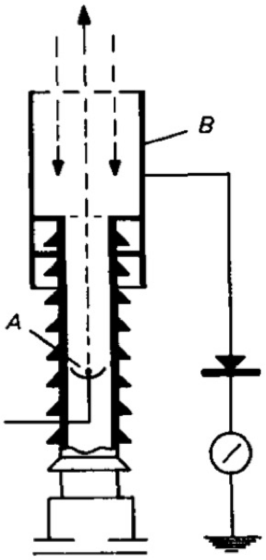

Abb. 3: „Experimentalschema V einer sukzessiven Entladung hochgespannter Ströme. Würde nach diesem Schema zumindest in stark gewittergefährdeten Gebieten verfahren, dann könnte es dort keine Blitzeinschläge mehr geben.“ A = Lichtquelle, B = Gitterantenne als Elektronenfalle

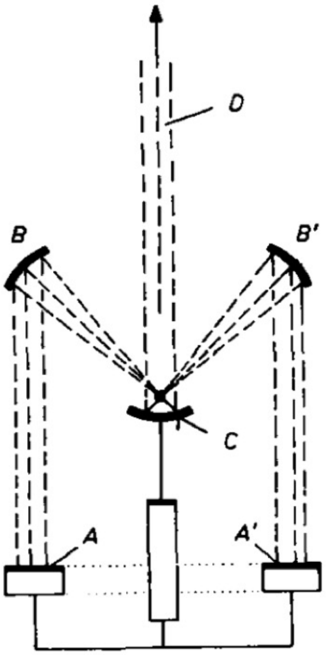
◀

▶

Abb. 4: Experimentalschema VI, „Quantenturbotron“. Die Ultraviolett-Strahlung von A und A’ wird durch die Parabolspiegel B und B’ nach G konzentriert. Dort wird ein leichtes Gas zugeführt und die Strahlung nun in Richtung D gesandt, wo sie einen mit Knallgas gefüllten Ballon in 1000 m Abstand „mit Sicherheit zur Explosion“ bringt



[Fig. 3: “Experimental scheme V of a successive discharge of high voltage currents. If this scheme were to be applied at least in thunderstorm endangered areas, then lightning strikes could no longer occur there.” A = light source, B = grid antenna as electron trap.

Fig. 4: Experimental scheme VI, “quantum turbotron.” The ultraviolet radiation of A and A' is concentrated to G by the parabolic mirrors B and B'. There, a light gas is supplied and the radiation is now sent in the direction of D, where it causes a balloon filled with oxyhydrogen gas to “explode” at a distance of 1000 m.]

Figure C.97: Diagrams from a page left behind in Switzerland by Hans Ehrhardt/Engelke.

Der Erfinder wartet mit konkreten Vorschlägen auf: Das Experimentalschema V für seine Versuche (Abb. 3) zeigt eine Röhre, durch die das Licht an der Lichtquelle A senkrecht nach oben geschickt wird, während B eine “Gitterantenne” ist, die am Isolator abgebogen ist. Sie dient als “Elektronenfalle”. Mit dieser Anordnung, dem “Quantenturbutron”, will der Erfinder Elektronen mit dem Lichtstrahl mitschiessen und sie zur Abgabe grosser Energien zwingen, denn: “sind sie (die Elektronen) einmal eingefangen und ausgerichtet, dann geben sie grosse Mengen Energie ab”. (S. 19)

Ein anderes aufschlussreiches Experimentalschema zeigt Abb. 4. Die Bildlegende enthält, was der Erfinder dazu sagt.

The inventor comes up with concrete proposals: The experimental scheme V for his experiments (Fig. 3) shows a tube through which the light at light source A is sent vertically upwards, while B is a “grating antenna” which is bent off at the insulator. It serves as an “electron trap.” With this arrangement, the “quantum turbutron,” the inventor wants to shoot electrons with the light beam and force them to emit large energies, because: “Once they (the electrons) are captured and aligned, they emit large amounts of energy.” (p. 19)

Another informative experimental scheme is shown in Fig. 4. The caption contains what the inventor says about it.

[The unnamed author of this article stated that he never met Ehrhardt/Engelke or saw his experiments in person, yet he proceeded to spend most of the article ridiculing Ehrhardt/Engelke as an uneducated crackpot who was trying to build perpetual motion machines. (Figs. C.93–C.95 look nothing like perpetual motion machines or the work of a scientific illiterate.) However, the unnamed author did find a few pages about Ehrhardt/Engelke's research that had been written by Ehrhardt/Engelke or by his Swiss scientific evaluators. The author quoted a few intriguing lines and two figures from those documents.

The provided information is insufficient to judge how or whether Ehrhardt/Engelke's designs would work, but they do offer some hints:

- The unnamed author seemed to have reason to believe that Ehrhardt/Engelke's research on producing powerful light beams dated back to wartime work.
- Ehrhardt/Engelke dubbed his device a “quantum turbo.” Considering that a “turbojet” produces a highly ordered, tightly directed jet or stream of gas, a “turbo” that produces a highly ordered, tightly directed stream of “quanta” (photons) would not be a bad description of a laser.
- The device contained a gas in an optically transparent glass tube that was electrically excited at the desired energy, which would certainly be reasonable in a laser.
- The device used mirrors, as would be expected in a laser.
- The device was ultimately intended to produce a beam of ultraviolet light. The beam photographed over the Sarner See appears to be visible light (unless the film was exposed by ultraviolet light), but perhaps Ehrhardt/Engelke's current experiments used visible light as a stepping stone to future experiments with ultraviolet.
- The device was intended to produce a highly focused light beam of sufficient intensity to heat objects (balloons, snow, or aircraft) at a distance, or if short-wavelength ultraviolet light were used, perhaps even to create enough ionization in the air to affect the preferred direction of lightning discharges from thunderstorms.]

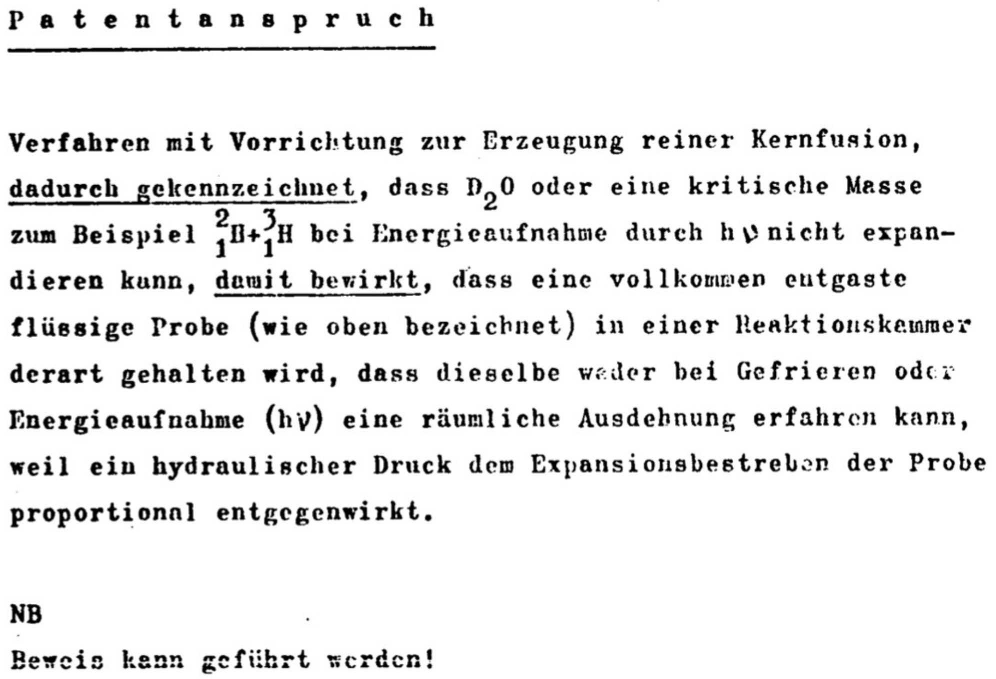
(71) Anmelder: Proton-Physik Forschungsgesellschaft mbH, 5600 Wuppertal

(72) Erfinder: Engelke, Jonas; Thedens, Elke, Dr.; 8000 München



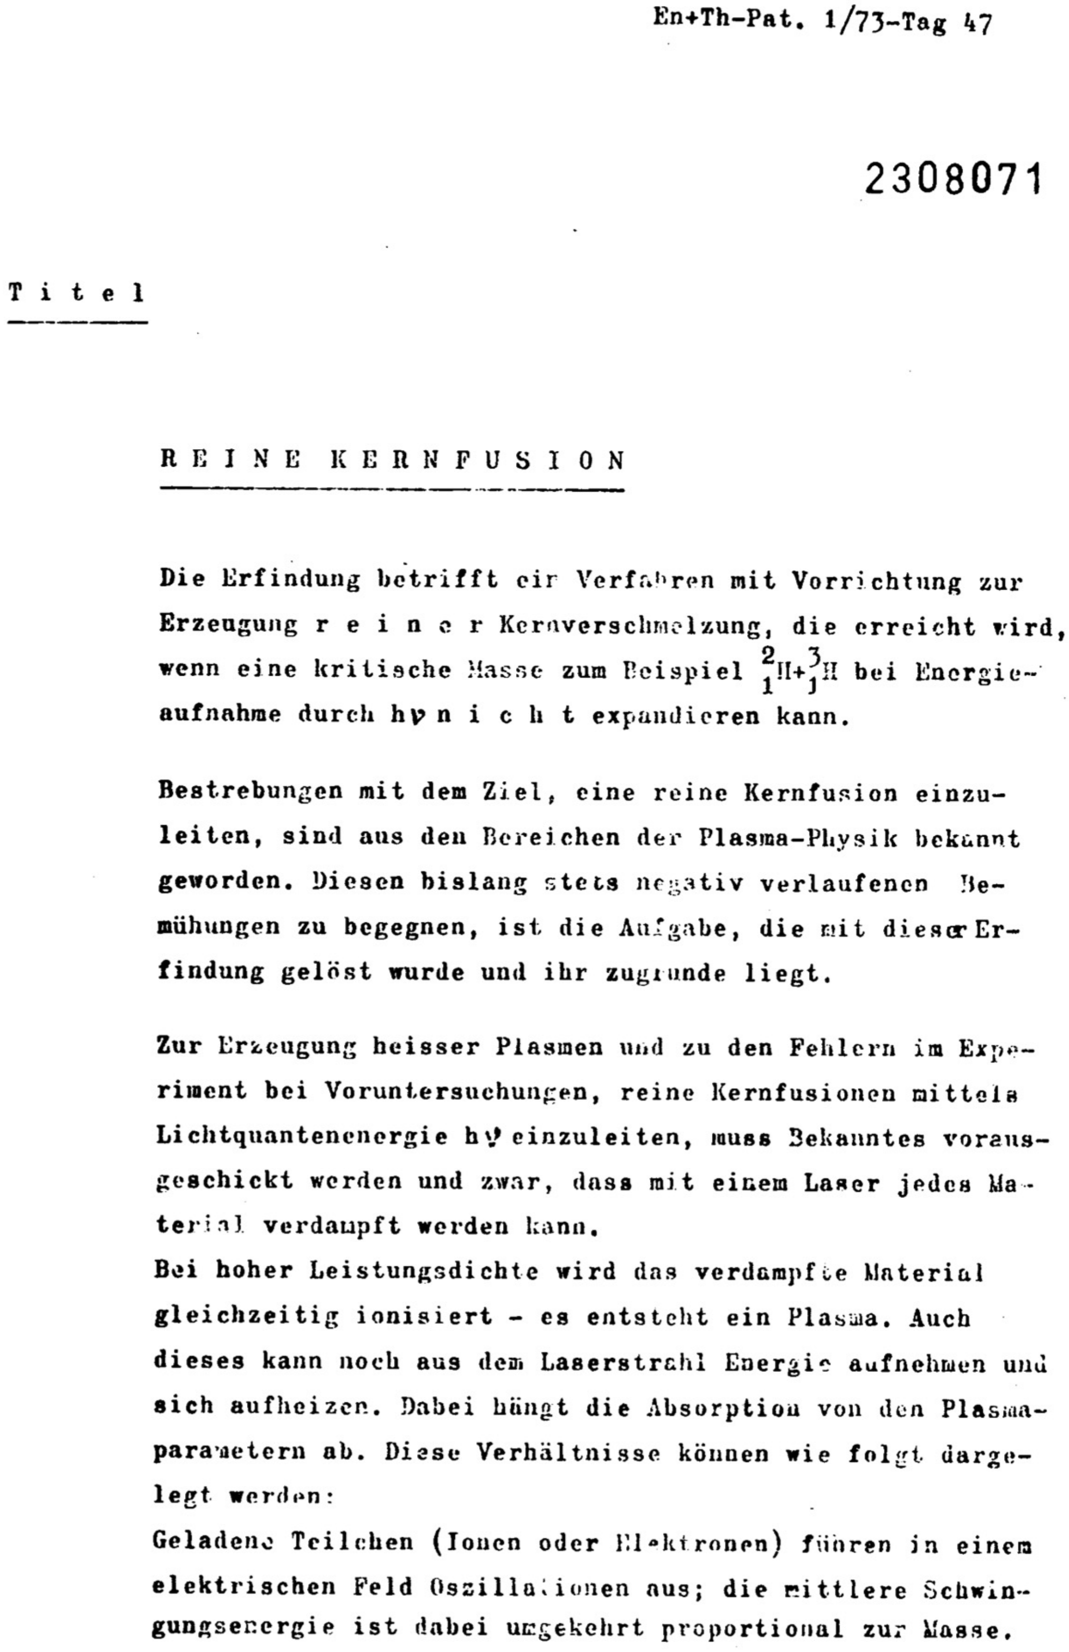
Patentanspruch

Verfahren mit Vorrichtung zur Erzeugung reiner Kernfusion, dadurch gekennzeichnet, dass D_20 oder eine kritische Masse zum Beispiel ${}^2_1H+{}^3_1H$ bei Energieaufnahme durch $h\nu$ nicht expandieren kann, damit bewirkt, dass eine vollkommen entgaste flüssige Probe (wie oben bezeichnet) in einer Reaktionskammer derart gehalten wird, dass dieselbe weder bei Gefrieren oder Energieaufnahme ($h\nu$) eine räumliche Ausdehnung erfahren kann, weil ein hydraulischer Druck dem Expansionsbestreben der Probe proportional entgegenwirkt.

NB

Beweis kann geführt werden!

Figure C.98: In 1973, an inventor listed as Jonas Engelke filed a detailed patent application (later issued as German patent DE2308071) on a method of inducing nuclear fusion reactions using converging high-power laser beams. Was the inventor the same person as the mysterious Engelke/Ehrhardt from a decade earlier?



En+Th-Pat. 1/73-Tag 47

2308071

Titel

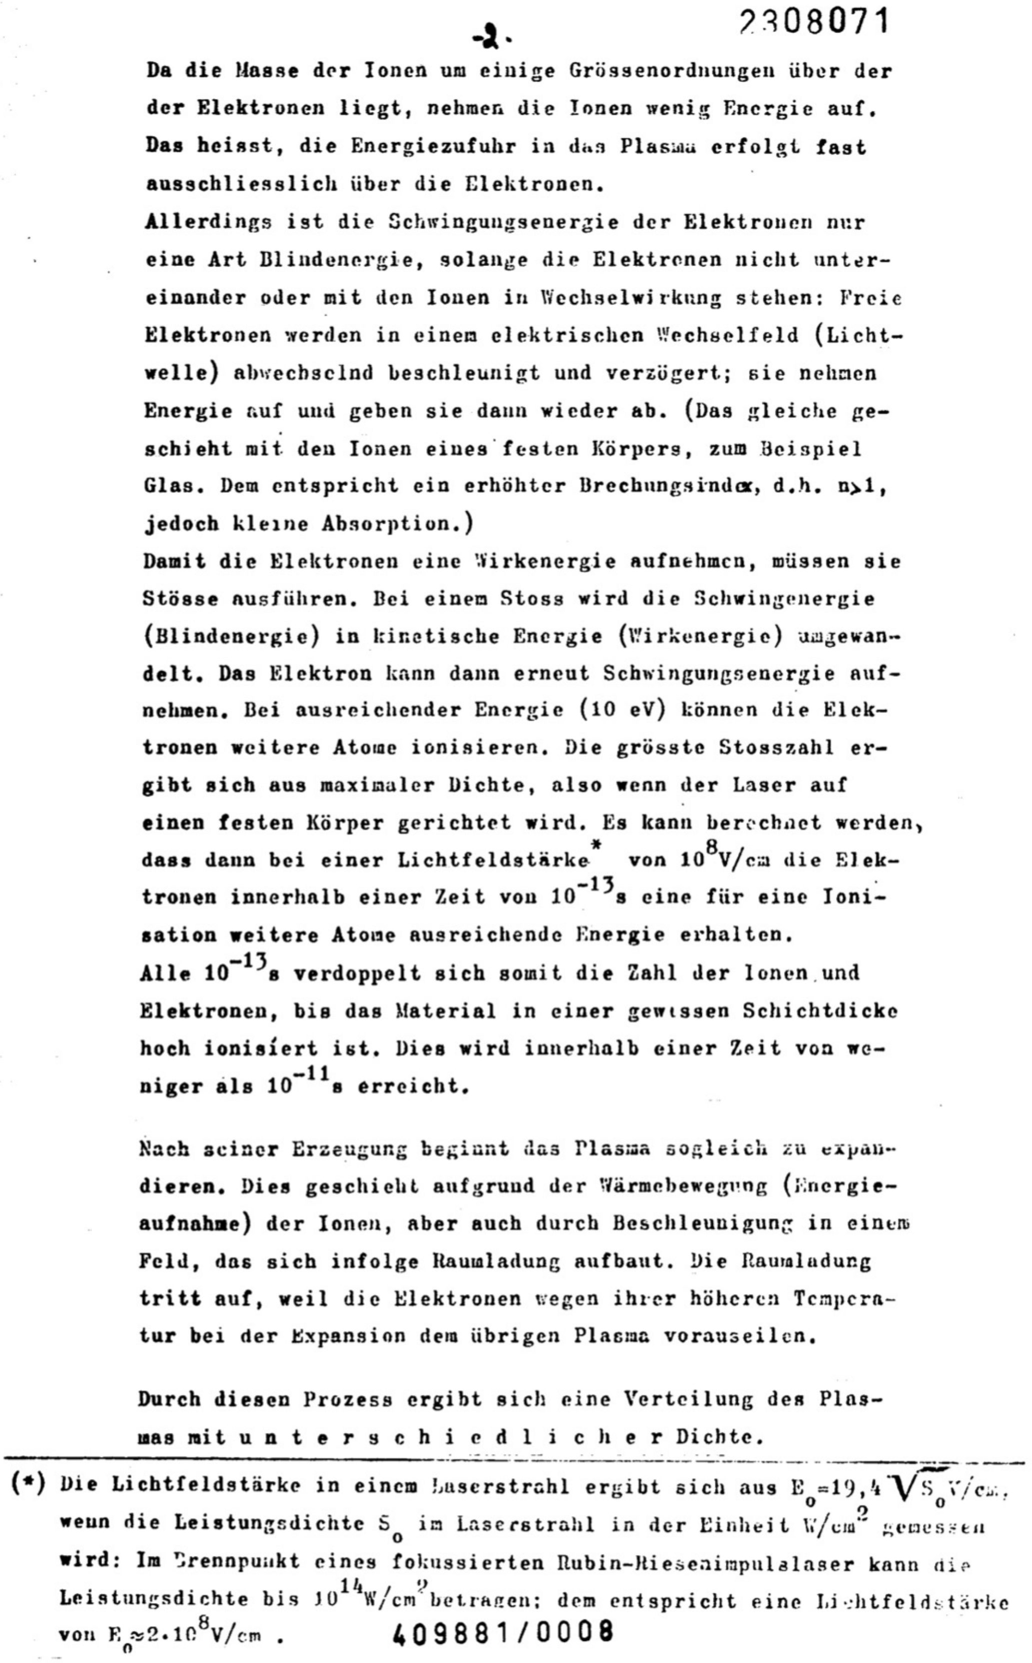
REINE KERNFUSION

Die Erfindung betrifft ein Verfahren mit Vorrichtung zur Erzeugung reiner Kernverschmelzung, die erreicht wird, wenn eine kritische Masse zum Beispiel $^{2}_{1}H+^{3}_{1}H$ bei Energieaufnahme durch $h\nu$ nicht expandieren kann.

Bestrebungen mit dem Ziel, eine reine Kernfusion einzuleiten, sind aus den Bereichen der Plasma-Physik bekannt geworden. Diesen bislang stets negativ verlaufenen Bemühungen zu begegnen, ist die Aufgabe, die mit dieser Erfindung gelöst wurde und ihr zugrunde liegt.

Zur Erzeugung heisser Plasmen und zu den Fehlern im Experiment bei Voruntersuchungen, reine Kernfusionen mittels Lichtquantenenergie $h\nu$ einzuleiten, muss Bekanntes vorausgeschickt werden und zwar, dass mit einem Laser jedes Material verdampft werden kann.
Bei hoher Leistungsdichte wird das verdampfte Material gleichzeitig ionisiert – es entsteht ein Plasma. Auch dieses kann noch aus dem Laserstrahl Energie aufnehmen und sich aufheizen. Dabei hängt die Absorption von den Plasmaparametern ab. Diese Verhältnisse können wie folgt dargelegt werden:
Geladene Teilchen (Ionen oder Elektronen) führen in einem elektrischen Feld Oszillationen aus; die mittlere Schwingungsenergie ist dabei umgekehrt proportional zur Masse.

Figure C.99: In 1973, an inventor listed as Jonas Engelke filed a detailed patent application (later issued as German patent DE2308071) on a method of inducing nuclear fusion reactions using converging high-power laser beams. Was the inventor the same person as the mysterious Engelke/Ehrhardt from a decade earlier?



-2- 2308071

Da die Masse der Ionen um einige Grössenordnungen über der der Elektronen liegt, nehmen die Ionen wenig Energie auf. Das heisst, die Energiezufuhr in das Plasma erfolgt fast ausschliesslich über die Elektronen.

Allerdings ist die Schwingungsenergie der Elektronen nur eine Art Blindenergie, solange die Elektronen nicht untereinander oder mit den Ionen in Wechselwirkung stehen: Freie Elektronen werden in einem elektrischen Wechselfeld (Lichtwelle) abwechselnd beschleunigt und verzögert; sie nehmen Energie auf und geben sie dann wieder ab. (Das gleiche geschieht mit den Ionen eines festen Körpers, zum Beispiel Glas. Dem entspricht ein erhöhter Brechungsindex, d.h. $n>1$, jedoch kleine Absorption.)

Damit die Elektronen eine Wirkenergie aufnehmen, müssen sie Stösse ausführen. Bei einem Stoss wird die Schwingenergie (Blindenergie) in kinetische Energie (Wirkenergie) umgewandelt. Das Elektron kann dann erneut Schwingungsenergie aufnehmen. Bei ausreichender Energie (10 eV) können die Elektronen weitere Atome ionisieren. Die grösste Stosszahl ergibt sich aus maximaler Dichte, also wenn der Laser auf einen festen Körper gerichtet wird. Es kann berechnet werden, dass dann bei einer Lichtfeldstärke* von 10^8V/cm die Elektronen innerhalb einer Zeit von 10^{-13}s eine für eine Ionisation weitere Atome ausreichende Energie erhalten.

Alle 10^{-13}s verdoppelt sich somit die Zahl der Ionen und Elektronen, bis das Material in einer gewissen Schichtdicke hoch ionisiert ist. Dies wird innerhalb einer Zeit von weniger als 10^{-11}s erreicht.

Nach seiner Erzeugung beginnt das Plasma sogleich zu expandieren. Dies geschieht aufgrund der Wärmebewegung (Energieaufnahme) der Ionen, aber auch durch Beschleunigung in einem Feld, das sich infolge Raumladung aufbaut. Die Raumladung tritt auf, weil die Elektronen wegen ihrer höheren Temperatur bei der Expansion dem übrigen Plasma vorauseilen.

Durch diesen Prozess ergibt sich eine Verteilung des Plasmas mit unterschiedlicher Dichte.

(*) Die Lichtfeldstärke in einem Laserstrahl ergibt sich aus $E_0=19,4\sqrt{S_0}$ V/cm, wenn die Leistungsdichte S_0 im Laserstrahl in der Einheit W/cm^2 gemessen wird: Im Brennpunkt eines fokussierten Rubin-Riesenimpulslaser kann die Leistungsdichte bis 10^{14}W/cm^2 betragen; dem entspricht eine Lichtfeldstärke von $E_0\approx2\cdot10^8$V/cm .

-3-

Je nach der Dichte verhält sich nun das Plasma unterschiedlich: Bei kleiner Dichte bzw. Elektronenkonzentration fehlt die Wechselwirkung mit anderen Elektronen oder Ionen; das Laserlicht wird nicht absorbiert. Bei grosser Dichte ergibt sich eine entsprechend grosse Absorption, sofern das Laserlicht in das Plasma eindringen kann.

Zwischen den beiden Bereichen geringer Absorption bzw. hoher Reflexion liegt eine Zone, in die der Laserstrahl eindringt und in der er absorbiert wird. Es ist dies die Zone mit einer Elektronenkonzentration n=np, wobei np die Konzentration bedeutet, bei der die Plasmafrequenz (kreisfrequenz) $\omega p = \sqrt{4 \pi e^2 np/m}$, annähernd gleich der Frequenz des Laserlichts ist (m ist die Elektronenmasse, e die Elementarladung). Die Strahlung eines Lasers wird somit im Wesentlichen nur in einem Bereich mit günstiger Elektronenkonzentration absorbiert. Der Bereich erstreckt sich über fast eine Zehnerpotenz um diesen Wert, er liegt um annähernd ein bis zwei Zehnerpotenzen unter der Konzentration im festen Material ($\approx 10^{22}$ cm^{-3}). Die Ausdehnung des Bereichs hängt von der Versuchsbedingung ab, sie kann unter Umständen einige 10^{-2} cm betragen.

Unter Anwendung dieser Erkenntnisse wurden bereits zahlreiche Experimente zur Erzeugung heisser Plasmen ausgeführt. Das Laserlicht wurde dabei auf Lithiumhydrid oder Lithiumdeuterid oder auf festen Wasserstoff bzw. festes Deuterium gerichtet. Gemessen wurden Ionenenergien von mehr als 1000eV, entsprechend Ionentemperaturen von mehr als 10 000 000 °K.
Es gibt auch Arbeiten, bei denen man den Laserstrahl nicht auf festes Material richtet, sondern das Plasma in einem Gas erzeugt. Man arbeitet dabei mit zwei Laserimpulsen, die nacheinander von zwei Lasern emittiert werden, und nutzt die Eigenschaft der durch den ersten Impuls erzeugten Schockwelle aus.

Alle Arbeiten dieser Art sind Voruntersuchungen mit dem Ziel einer Kernfusion. Um dieses Ziel zu erreichen, müssen verschiedene Bedingungen erfüllt sein, und zwar Bedingungen hinsichtlich Dichte, Masse und Temperatur und hinsichtlich der Zeit, während ein Plasma auf hohen Temperaturen gehalten werden kann. Eine hohe Temperatur allein genügt nicht.

Figure C.101: In 1973, an inventor listed as Jonas Engelke filed a detailed patent application (later issued as German patent DE2308071) on a method of inducing nuclear fusion reactions using converging high-power laser beams. 2308071

-4-

Nach dem heutigen Stand der Lasertechnik können unter diesen Voraussetzungen diese Bedingungen nur erfüllt werden, wenn mehrere tausend der stärksten Laser gleichzeitig gezündet werden und ihre Leistung auf ein und dieselbe Probe gerichtet wird. Unter diesen Umständen wäre es prinzipiell möglich, mit Laserenergie eine Kernfusion zu bewirken.
(Russische Autoren berichten, dass in Laserplasmen bereits freie Neutronen nachgewiesen werden konnten, wie sie bei thermonuklearen Reaktionen entstehen.)

Wenn auch die Möglichkeit als gegeben erscheint, mit mehreren tausend Riesenimpulslasern eine Kernfusion einzuleiten, so wäre dieses Experiment nicht allein vom materiellen Einsatz her absurd, sondern auch von der Basis der Versuchsanordnung bereits infrage gestellt, weil eine grundlegende Voraussetzung zum Gelingen einer Fusion mit Laserimpuls bisher nicht beachtet wurde. Niemals darf eine Probe - damit es keine unterschiedlichen Dichten im Reaktionszentrum gibt - bei Energieaufnahme räumliche Veränderungen erfahren - sie darf nicht expandieren können! und damit ist hier auf das Kriterium der Fehler im experimentellen Bereich hingewiesen.
Eine Probe muss bei Energieaufnahme an homogener Dichte zunehmen und endlich diejenige dichte Packung erreichen, die zwangsläufig zu einer Kernfusion führt. Ist diese Voraussetzung gegeben, genügen bereits Quantenimpulse von zwei mal 10^{14}W/cm^2, um freie Neutronen zu erzeugen, und vier mal 10^{14}W/cm^2, um eine reine Kernfusion einzuleiten.

Hauptgegenstand der vorliegenden Erfindung ist eine Reaktionskammer in der Konfiguration eines Simultan-Autoklaven, der extrem hohe innere Drücke bei grosser Kälte- oder Wärmeeinwirkung mit Sicherheit aufnehmen kann.

Im Zeichnungsblatt 1_A ist diese Reaktionskammer mit zwei aussen angeordneten Impulslasern (A-B) schematisch im Querschnitt dargestellt.
Das Block-Schema 1_B gibt die Schrittfolge zur Ausübung des Verfahrens an.

Figure C.102: In 1973, an inventor listed as Jonas Engelke filed a detailed patent application (later issued as German patent DE2308071) on a method of inducing nuclear fusion reactions using converging high-power laser beams. Was the inventor the same person as the mysterious Engelke/Ehrhardt from a decade earlier?

-5-

Flüssigkeitsmoleküle sind in ständiger regelloser Bewegung (Wärmebewegung) und leicht gegeneinander verschiebbar. Bei konzentrierten Energieimpulsen, mit zum Beispiel einem fokussierten Laser, erhalten Flüssigkeitsmoleküle durch thermische Ausdehnung beträchtliche Bewegungsenergien und werden regelrecht aus einem Fokus herausgeschleudert.

Diesbezügliche Experimente mit Eiskristallen haben ebenfalls negative Resultate ergeben, weil unter anderem ein Kompressionsdruck während der angestrebten Reaktionsphase fehlte.

Bei Untersuchungen mit heissen Plasmen eine Kernfusion herbeizuführen, reichte die Energie eines Magnetfeldes nicht aus, die unterschiedlichen Dichten zu kompensieren, die in Erscheinung treten, wenn ein ringförmig gehaltenes (ohnehin labiles Plasma) an irgendeinem Punkt unterschiedliche Dichten durch zusätzliche Energieaufnahme erfährt.

Zusammen: Eine hohe Temperatur allein genügt nicht. Bei allen bisher bekanntgewordenen Experimenten fehlte der optimale Druck und die homogene Dichte im Reaktionszentrum.

Der vorliegenden Erfindung liegt zugrunde, Flüssigkeitsmoleküle im Erstarrungszustand (Gefrierzustand), also örtlich gebunden, derart mit konzentrierten Energien zu erreichen, dass weder eine örtliche Verschiebung oder eine Expansion der Moleküle durch Energieaufnahme stattfinden kann. Diese grundlegenden Bedingungen sind erfüllt, wenn der Gefrierzustand einer flüssigen Probe unter Druck erfolgt.

Die auf dem Zeichnungsblatt 1_A im Schnitt schematisch dargestellte Reaktionskammer G trägt Arbeitsdrücke bis zu $3 \cdot 10^6$ at. und hat zweckmässig die Gestalt einer Hohlkugel.
Zwei kegelförmige Linsen C-D zum Beispiel bestehend aus NaCl oder Quarz, sind derart in der Wandung gelagert, dass jeweils ihr Kegelstumpf nach innen gerichtet ist. Aussen angeordnet befinden sich zwei Impulslaser A - B, die auf einer optischen Bank so ausgerichtet sind, dass bei Impuls vermittels Kegellinsen C - D im Reaktionsraum F ein Fokus E erzeugt wird.

Die Experimentalschritte nach dem Blockschema auf Zeichnungsblatt 1_B werden wie folgt durchgeführt: Das Abfüllen der flüssigen Probe wird mit der Vakuum-Abfüllgruppe A bis E bewirkt, wobei die Probe zunächst durch das Ventil 5 in den Entgasungskolben C gezogen wird. Dabei sind die Ventile 3 und 4 zu verschliessen. Ist die erforderliche Flüssigkeitsmenge in C eingeströmt, wird das Ventil 5 geschlossen und ein Ultraschallgeber im Entgasungskolben C eingeschaltet.

Jetzt wird die Probe durch vorsichtiges Abpumpen entgast, und das Ventil 2 kann erst verschlossen werden, wenn die Flüssigkeit völlig zum Stillstand gekommen ist. Ist dies geschehen, wird das Ventil 2 geschlossen, die Vakuumpumpe A abgeschaltet und danach das Belüftungsventil 3 geöffnet.

In dieser Folge erhält die Sicherheits-Vakuumgruppe G-H den Befehl, solange ein Grobvakuum von 10^{-3} Torr vor den Kegellinsen C-D (Zeichnungsblatt 1_A) aufrechtzuerhalten, bis der Füllvorgang mit der Vakuumfüllgruppe I-J beendet ist. Zu diesem Zweck werden die Ventile 4 und 7 geöffnet, Ventil 8 geschlossen und die Vakuumpumpe J eingeschaltet.

Der Reaktionsraum F ist gefüllt, sobald Flüssigkeit in die Vakuumfalle I eintritt, und es wird zunächst das Ventil 4, dann das Ventil 7 verschlossen, das über Elektroimpuls simulten die Ventile (H und I, Zeichnungsblatt 1_A) der Reaktionskammer verschliesst.

Mit dem Öffnen des Ventils 8 wird auch die Vakuumpumpe J abgeschaltet.

Nach Beendigung dieses Vorganges muss die Sicherheitsvakuumgruppe G-H ebenfalls abgeschaltet und die (Kegellinsen C-D im Zeichnungsblatt 1_A) freigelegt werden. Vor Abschalten der Vakuumpumpe G, ist Ventil 6 zu öffnen.

Der Laserimpuls wird eingeschossen, wenn der Gefrierzustand der Probe einen Druck von 10^5 at. erreicht hat.

Figure C.104: In 1973, an inventor listed as Jonas Engelke filed a detailed patent application (later issued as German patent DE2308071) on a method of inducing nuclear fusion reactions using converging high-power laser beams. Figure C.105: In 1973, an inventor listed as Jonas Engelke filed a detailed patent application (later issued as German patent DE2308071) on a method of inducing nuclear fusion reactions using converging high-power laser beams. Was the inventor the same person as the mysterious Engelke/Ehrhardt from a decade earlier?

[There are many mysteries regarding Hans Ehrhardt/Engelke and his laser-like experiments:

- “Ehrhardt” was clearly not the person’s real name, and “Engelke” likely was not either. If his real last name was something else, it may have begun with an E. At least one of his names was an alias and he could have chosen anything, yet he chose to use the same initial letter for some reason. (E is a somewhat less common first letter for German last names.)

- Hans Ehrhardt/Engelke was building and testing optics equipment for novel high-luminosity light sources. Did he have a formal university education and/or previous job experience in optics, perhaps under some other name?

- Swiss accounts said that Hans Ehrhardt/Engelke claimed to have been born in 1918, which would have made him 43–45 years old in 1961–1963. The 1961–1963 photos of Hans Ehrhardt/Engelke look like a man who was perhaps a decade older than that. While it is possible that Hans Ehrhardt/Engelke simply looked older than his true age due to the hard life he had led, there is the very real possibility that he was born earlier than he claimed. His true age would have large implications for what his real identity might have been, and what his true educational and work background might have been.

- Hans Ehrhardt/Engelke had a wife and four children in 1961–1963. Can more information about him be traced from his family’s history either before or after that time period?

- Hans Ehrhardt/Engelke claimed that he helped to develop fuel-air explosives during the war. One of the main groups conducting such work was a large Luftwaffe-funded team led by Mario Zippermayr (see p. 541). Had Hans Ehrhardt/Engelke been a member of Mario Zippermayr’s group (or perhaps some other fuel-air explosive group) during the war?

- Hans Ehrhardt/Engelke had worked for the Russians but wanted to leave that behind. He likely would have applied to work for the United States. Do U.S. Foreign Scientist Case Files at NARA (or other files) contain information on Hans Ehrhardt/Engelke under those or any other names?

- Hans Ehrhardt/Engelke appeared to have been blacklisted, wandering from place to place, unable to find someone (other than the Russians) willing to provide him a home and a job. That would have been a good motivation not to use his real name and identity, and suggests that he was not using his real name and identity.

- What was the real name, age, and background of Hans Ehrhardt/Engelke?

- The laser-like research of Hans Ehrhardt/Engelke seemed to date back to the war, based on some of his mysterious statements. If so, was Ehrhardt/Engelke’s research also related to the wartime work of Wilhem von Meyeren or others?

- How widespread, and how advanced, was work on laser-like technologies in the Third Reich?

- What influence did German-derived laser-like technologies have on the development of lasers in the United States, Russia, and other countries in the 1950s–1960s?

- What additional relevant documents can be discovered in archives or family collections around the world?]

William B. Bridges. Laser Oscillation in Singly Ionized Argon in the Visible Spectrum. *Applied Physics Letters* 4:7:128 (1964)

Ten new laser wavelengths in the green and blue portions of the visible spectrum have been observed in a pulsed argon discharge. The responsible transitions occur in the singly ionized state of the Ar atom (A^{II} spectrum). Measured wavelengths, tentative level assignments, and a few estimates of [...]

[Officially, the first laser was not built until 1960 (by Ted Maiman), and the argon gas laser was not invented until 1964 (by William Bridges), both at Hughes Aircraft in the United States.]

C.4 Focused Sound Waves

[German-speaking scientists took the lead in harnessing focused sound waves for a wide variety of applications, ranging from the first ultrasound imaging devices to the first directed acoustic weapons. The following documents demonstrate that those technologies were developed and successfully demonstrated in Germany and Austria during the war, and then directly transferred to other countries in 1945, leading to modern acoustic and ultrasound devices.]

BIOS 1504. *Industrial Applications of Ultrasonics.* pp. 3–11 [Reports on two laboratories developing ultrasonic generators and applications of them.]

I. PRODUCTION OF ULTRASONICS.

(a) General.

In the last ten years possible industrial applications for ultrasonics became apparent, and Siemens-Schuckert (S.S.) started research work on the production of intense sources of ultrasonics just prior to the war. [...]

Most of the development work was carried out with magneto strictive and piezo-electric generators, but some work was also done with an acoustic mechanical method based on the Galton whistle. The magneto strictive generators were usually worked at frequencies between 10 and 25 k.c., the piezo-electric generators at 300–400 k.c. and the whistle at 15–20 k.c. Each of these methods had its own particular advantages, and the choice of the one to be employed depends on the particular application.

(b) Magneto strictive generators.

These depend upon the property of ferromagnetic metals to change their dimensions in the direction of an applied magnetic field. In practice an alternating current was superimposed on constant D.C. current, both of which magnetised a nickel rod which is set into oscillations of the same frequency as the A.C. current. Only if the frequency is equal to the natural mechanical frequency of the rod are large amplitude oscillations produced. The ultrasonics are radiated from the end surfaces of the rod into the surrounding medium. [...]

Fig. 1 shows the fundamental arrangement for treating liquids. The nickel rod (1) is let in through the bottom of the glass container (2) and is partly immersed in the liquid (4) which can be circulated through tubes (6) and (7). The tube is held by a rubber gasket (3) which should be at a node of the rod so as not to damp the oscillations. The external section of the rod is surrounded by a coil (5) through which both the A.C. and D.C. is passed. Sometimes two coils are employed; one to carry the A.C. and the other the D.C. [...]

The oscillator is tuned before use to the natural frequency of (1) with L_2. The nickel rod is usually 11 cms. long corresponding to 23 k.c. or sometimes 20 cms. corresponding to 12.75 k.c. An experimental oscillator was said to give 300 watts of ultrasonics with a current consumption of 800 watts.

The major advantage of the magneto strictive oscillator is its simplicity and ruggedness, and its major disadvantage the low frequencies at which it has to operate since it depends on the natural frequency of the rod. Another disadvantage often encountered is the small area from which the ultrasonics radiate. These disadvantages are absent in a piezo-electric generator.

(c) Piezo-electric oscillators.

Quartz crystals were the only piezo-electric materials employed. A suitably cut quartz crystal oscillated with a frequency depending on the thickness and an amplitude depending on the applied voltage. [...]

S.S. always mounted their crystal in oil to prevent arcing, and a typical ceramic container [...] is shown in Fig. 5. [...]

Fig. 6 shows the generator in action. The materials to be irradiated are placed in thin-walled glass containers and suspended in the oil fountain[...]

The generator uses 2.7 k.w., dissipates 1.6 k.w. of high frequency and produces 400 w. of ultrasonics. [...]

(d) Mechanical generators.

It is very difficult to build large generators of the magneto strictive or piezo-electric type, and so for industrial applications many small units would have to be operated side to side. This is cumbersome and expensive and in order to obtain high power generators S.S. developed the ultrasonic whistle, which proved valuable for making emulsions.

The general design of all of these is based on a Galton whistle, but operated with a liquid instead of a gas.

Fig. 10 shows a simple type of Galton whistle, consisting of a tube (1) with a hole (2) having a sharp lip (5). The air stream passes through the narrow slit (6) impinging on the lip which oscillates. The air column (7) will oscillate in resonance if the plug (4) is suitably adjusted.

Exactly the same principle applies when liquid is substituted for a gas. However, S.S. preferred to use a slightly modified design shown in Fig. 11. Here the liquid is forced through a very narrow circular orifice (6) formed by the plug (10), held in position by vanes (11) and impinges on a circular lip (5). [...]

A performance result of a whistle of the last type was quoted. The whistle used had an overall length of 15–20 cms. and 50 litres of emulsion were prepared in a few seconds. The pressure at which the liquid was expelled through the whistle was thought to have been between 10 and 20 atmospheres. The distance between orifice and lip was approximately 1 cm. and the frequency produced about 15 k.c.

These were the only quantitative data which the S.S. personnel interviewed could remember.

II. APPLICATIONS OF ULTRASONICS.

(a) General.

[...] S.S. were not primarily interested in finding applications for ultrasonics. Their interest lay in developing methods of production, and they preferred to carry out joint researchers with prospective users. Occasionally they even made available equipment to firms who did not disclose what they intended to do with it. [...]

(c) Emulsification.

The most common use for ultrasonics is the formation of emulsions or dispersion in liquids. [...] From an experimental point of view, piezo-electric generators were convenient, since the material to be irradiated need only be placed in a beaker and held in the oil fountain. A number of generators of this type illustrated in Fig. 9 were sold for this purpose.

In Professor Hertz's laboratory magneto striction oscillators were developed, and Drs. Schöfer and Barwich studied the mechanism of emulsion formation. This was caused, not by the sound waves themselves, but by the cavitation effects produced in the liquid. The breaking up of the droplets occurred entirely in the zones of cavitation. This is not a new observation but appears to have been very thoroughly substantiated at S.S.

It is very advantageous to produce a course dispersion before breaking up to emulsion size. This was done by low frequency agitation (at 100 cycles per sec.) with the aid of an electro-magnetic feed with waves 50 cycle A.C. [...]

(d) Disinfection.

Ultrasonics were tried for the disinfection of water, milk and other liquids. Definite effects were observed but they were not striking and work was discontinued in favour of promising methods, but it was hoped to re-examine this question later. It was found that some non-pathogenic organisms, such as B[acillus]. coli, were destroyed most effectively, but the radiations had much less effect on cocci. [...]

(g) Soldering.

It is well known that the presence of an oxide layer on the surfaces of metals to be soldered prevents a firm joint from being formed. Normally the oxide layer is removed with a suitable flux. [...] S.S. discovered that if the molten solder when in contact with the metal is in ultrasonic vibrations then a good join is produced without the necessity for any flux. The vibrations break up the oxide layer and expose the metal to the solder in which the former remains dispersed without impairing the strength of the join. [...]

S.S. had intended in 1941 to use several hundred of these ultrasonic soldering irons in their valve factories, but urgent war requirements prevented more than a few from being built.

(h) Welding.

Ultrasonics were applied to electrical welding but proved of doubtful value. [...] If the two electrodes are set into vibration whilst the welding current is heating and melting the point at which the metals are to be joined, an improvement of the crystal structure of the weld is obtained. Yet in spite of a considerable decrease in the grain size the joint is not appreciably strengthened.

Vibrations of lower frequencies were examined and it was found that the lower the frequency the stronger the joint. A single blow during the welding produced the strongest joint. However, only high frequency oscillations produced the improved crystal structure at the weld.

4. Ultra-sonic Methods of Testing

The R.R.S. was alive to the possibility of applying ultra-sonics but had only used the method for the detection of laminations. It appears that 4 sets had been constructed using transmitted sonic energy and they had all been destroyed by bombing. The output was 30 watts at a frequency of one megacycle.

BIOS 609. *Non-destructive Testing of Materials.* pp. 2–3.

[...] Details of the detector used were obtained partly from Professor Trendelburg but chiefly from Dr. Pohlman at Erlangen. [...]

A schematic diagram of one form of the apparatus used is shown in Fig. 1. (A photograph of this apparatus was seen.) The high frequency source is the usual quartz crystal, oscillating at a frequency of about 1.6 MHz. It is coupled to the "work" by mercury, oil or vaseline. The detecting and observing unit consists of a tubular housing, full of xylene, which contains the detector cell, a semi-transparent mirror and an ordinary optical lens. The housing is closed at one end by a sonic lens of aluminium and at the other end by a viewing screen. A lateral branch of the housing encloses a lamp for illumination of the cell.

The velocity of sound in aluminium is nearly four times its velocity in xylene and so a sonic beam passing from aluminium into xylene, by way of a surface, which is concave with respect to the aluminium, is converged. The pattern formed in the cell is thus a reduced image of the beam as it passes (and is modified by any flaws) through the work. To observe this pattern an image of the cell is projected optically on the viewing screen. The scheme is sufficiently indicated in Fig. 1.

Photographs were seen of a considerable number of cell patterns obtained on examining such subjects as steel containing hair cracks, laminated strip, spot welds, light alloy bars. The degree of detail shown was far higher than I expected.

Considerable use is made of sonic lenses. One example is shown in Fig. 1. Commonly they are constructed of two thin saucer shaped sheets of brass or aluminium fastened together in the form of a double convex lens, the vessel so formed being filled with some convenient liquid such as carbon tetrachloride. If this arrangement is immersed in xylene it acts as a converging lens (the velocity of sound in xylene is 1.45 times its velocity in carbon tetrachloride). Diverging lenses may be made on similar principles.

Obtaining efficient coupling between the oscillator and the work was made light of by Pohlman who said there was rarely any difficulty, though each case had to be considered on its merits. Considerable distances in liquid are often traversed by the sonic beam. Bromoform is a common coupling liquid used.

The arrangement used for the examination of small shell blanks is indicated in Fig. 2. [...] The cell pattern forms in 1 to 2 seconds. Inspection is carried out at the rate of 500 per hour. [...]

17. INTERROGATION OF DR. POHLMAN, SIEMENS REINIGER,
ERLANGEN, 11/4/46.

Material Testing by Ultrasonics.

Dr. Pohlman's method was stated to give an actual picture of the faults in steel plates, and the equipment was stated to give a discrimination down to 0.4 of a millimetre. [...]

One model of this equipment was used by the Deutsche Waffen und Munition Werke at Posen to check the blanks for 20 mm. cannon shells at the rate of 600/hr. The apparatus was also used to check spot welds, and a further apparatus was used by Junkers to check a main butt weld in aircraft. Attached hereto is an account of his method written by Dr. Pohlman.

Unfortunately we were not able to check the claims made by Dr. Pohlman either as stated in the above account or in his attached account. Dr. Pohlman claimed that all equipments had been taken by the Russians, but Lt Cmdr. Goudge later informed us than an equipment of this type had been evacuated by the Americans. [...]

Medical Uses of Ultrasonics.

Dr. Pohlman is at present employed in experiments with ultrasonic generators for therapeutical purposes. These operated at 800 Kc/s and a power of about 1 watt/sq. cm. The application time was usually about 10 minutes and they were used in attempts to relieve asthma, sinus troubles, and rheumatism with some success.

[pp. 31–32:]

18.
IS IT POSSIBLE TO PRODUCE THERAPEUTIC EFFECTS BY MEANS OF ULTRASONICS?
by
DR. REIMAR POHLMAN. BERLIN.

Research has been pursued in many directions to determine the action and the effect of ultrasonics on living organisms. The results have been found to be mostly destructive, but a large number of phenomena remain unexplained. Micro-organisms were disrupted, red blood corpuscles expanded, lost their colour, and finally broke down, fish and small animals were killed, and the virulence of pathogenic organisms was enhanced or diminished according to the nature of the organism and the conditions of the experiment.

The cause of these very diverse phenomena may be partly ascribed to the following processes. An ultrasonic wave induces very violent dispersion of two media in one another owing to its high acceleration factor (reaching 10^8 cm/sec.^{2}). High intensities rupture the liquid, and lead to cavitation and to a fairly strong de-aeration connected therewith. Several investigators have been able to show that this cavitation accounts for many of the biological effects of ultrasonics. Upon raising the pressure i.e., reducing cavitation, the effects do not take place.

It is noteworthy that the phenomena mentioned occur practically exclusively at high intensities, so that the idea could not altogether be rejected that other effects might take place at lower intensities and possibly prove to be of a therapeutic nature. That theory received support from the characteristic properties of ultrasonic waves. [...]

These facts left the possibility open that it might be possible to produce therapeutic effects by means of ultrasonic radiation. Practical trials to discover and study these effects could only be carried out on individuals. A large number of preliminary trials had, of course, to be carried out and the limit of energy at which deleterious effects take place had to be determined in order to prevent injury under all circumstances. It was further necessary to ascertain whether latent or secondary lesions might not appear as sequelae of a larger number of normal exposures to the rays. And thirdly. the question arose as to whether more than a negligible percentage of the rays would reach the depth intended. Careful measurements showed that absorption of ultrasonics in human tissues is comparatively slight, but that it practically corresponds to that of a highly absorbent homogeneous liquid. As might be expected, absorption and hence the depth effect of ultrasonic radiation depends on the wave length; and it was found that radiation at a frequency of 800 kc/sec. drops by one half at a depth of 5 cm.

[pp. 35–38:]

19. MATERIAL TESTING BY ULTRASOUND IMAGE METHOD.
BY R. POHLMAN. ERLANGEN, 14/3/46.

[...] In this method the ultrasound radiated from a quartz crystal passes through the object to be tested and is then by means of an ultrasound lens imaged on to an image converter. The image converter makes visible the picture resulting from the flaws. [...]

Fig. 15 shows such photographs. At the top there is a model experiment in which two blocks of iron were screwed together. The picture on the right was obtained by radiating at right angles to the screw. One can see clearly the screw thread and the air gap which is between the milled surfaces of the two metal blocks which are pressed together. [...]

Trials on patients were carried out with the cooperation of two physicians, R. Richter and E. Parow, at the Martin-Luther-Hospital, Berlin. [...]

[p. 72:]

It was reported that Submarine Signals delivered an ultrasonic equipment to dairies for the purpose of treating milk, and it is found that milk so treated can be more readily absorbed by some infants; in some cases a litre of milk can be digested four times as fast after treatment, and in addition the treatment kills bacteria.

[In addition to Reimar Pohlman, some other important German-speaking pioneers of ultrasound imaging were:

- Karl Theodore Dussik (Austrian, 1908–1968) [www.ob-ultrasound.net/dussikbio.html]
- Theodor Hueter (German?, 19??–19??) [www.ob-ultrasound.net/hueter.html]
- Paul Kretz (German?, 19??–19??) [www.ob-ultrasound.net/kretztechnik.html]
- Heinrich Netheler (German?, 19??–19??) [www.ob-ultrasound.net/netheler.html]

As documented in BIOS 1504 and BIOS 1679, at least 22 different German and Austrian laboratories were doing research on ultrasonic generators and applications during the war. Reports such as these, as well as countless documents, hardware, and many of the scientists themselves were transferred to the United States, United Kingdom, Soviet Union, and other countries after the war. Presumably many postwar ultrasonic development programs in those countries could be traced back to the German-speaking creators.]

CIOS XXXII-77 = NavTecMisEu 198-45. *The Production of Intense Audio Sounds by an Intermittent Flame.*

SUMMARY

A project was sponsored by the Speer Ministry aimed at the production of a sound beam so intense it would render troops unfit for combat at ranges up to 15 kilometers. This project, which was pursued for two years, culminated in the development of an 800 cycle generator capable of producing a sound pressure of 1,000 microbars 60 meters from the source. Although this was a very loud source of sound, its effective range was found to be not over 100 meters. The details of the generator, which was based on an intermittent flame principle, is of some scientific interest.

1. Introduction

The information contained in this report was obtained during an interrogation of Dr. Richard Wallauschek who was a member of the Hochtal Laboratory at Lofer, Austria. This laboratory, which has been in existence since 1943, was a pet project of Reichsminister Speer and was originally known as Forschungsstelle-S. Major Barisani was director of the laboratory but during the closing weeks of the war Dr. Zippermayr was made a co-director. The laboratory employed about fifty people.

The development of intense sources of sound was the first major project assigned to the Hochtal Laboratory. The project was based on ideas of Dr. Walkhoff who convinced the Speer Ministry that enemy troops could be rendered unfit for combat by intense sound beams at ranges up to 15 to 20 kilometers. Dr. Wallauschek, formerly of Telefunken, was relieved from the Army to head to the project. Realizing the absurdity of the basic assumption, he agreed only to develop the loudest source of sound he could and make such tests as were required, a job he succeeded in extending over a period of two years.

The source of sound, finally evolved, was based upon the well-known principle of the intermittent flame. The frequency of the flame was controlled by a quarter wave-length resonant tube closely coupled to the combustion chamber. The sound was formed into a beam by use of a parabolic reflector. The best model built was capable of producing a sound pressure of 1000 microbars at 800 cps at a distance of 60 meters from the generator.

2. Description of the Apparatus

The apparatus is composed of two parts: a sound generator and a parabolic reflector. The external appearance of the part is shown in Fig. 1a. An explanation of the operation of the sound generator will be made with the help of the schematic diagram, Fig. 2a. It consists of a combustion chamber and a resonant tube coupled together, plus a water jacket which surrounds the entire unit. The combustion chamber is shown at the left end of Fig. 2a. Oxygen at a pressure of 6 atmospheres is introduced into the combustion chamber through an axially located tube having a 6 mm orifice. Methane is introduced at the same pressure through a second tube located near the side of the chamber. This gas is made to pass through a set of vanes which causes it to assume a whirling motion before it reaches the combustion region near the orifice of the oxygen tube. The arrangement of the vanes is illustrated in Figure 2b.

The rate of combustion is made to vary by the use of a quarter wave-length resonant tube acoustically coupled to the combustion chamber. The resonant tube has a small conical flare. The exact rate of flare has no significant effect upon the action of the device as long as its valve is small. The tube acts as if the right end is free and the left end blocked so that the fundamental resonance of the pipe is such that its length is equal to a quarter of a wave-length. A standing wave within the pipe produces fluctuations in pressure within the combustion chamber, which fluctuations will cause the rate of combustion to vary at the same frequency. The periodic release of thermal energy serves to maintain the system in oscillation. In order to increase the thermo-dynamical efficiency of the unit, both the combustion chamber and the resonant tube are surrounded by a pocket through which water is circulated, thus cooling the combustion products as they pass through the combustion chamber.

An approximate equal-pressure contour of the sound field produced by the generator above is shown in Figure 3. It is obvious that most of the sound is propagated radially from the sound generator, that is to say, a "disk" of sound is produced. The absence of propagation in the axial direction is caused by the well-known phenomenon of the scattering of sound by hot columns of gases.

The purpose of the original project was to produce a beam of sound—not a "disk" of sound. In order to produce a beam, the sound generator is mounted along the axis of a parabolic mirror with the open end of the resonant tube located in the focal plane. When so mounted, the contour of the sound field is changed from the disk of Figure 3 to the conical beam of Figure 4. This beam is neither narrow (as shown by the 30^o spread between the first minima) nor highly directive (as shown by the 3 to 1 ratio of amplitudes between the main beam and the first side lobe).

Several models using the above principles were constructed which varied in operating frequency from 400 to 1000 cps. The most powerful unit built operated at 800 cps and used the larger of the parabolic mirrors shown in Figure 1b, the diameter of which was 320 cm. This unit was able to produce a pressure of 1000 microbars on the axis of the main beam 60 meters from the generator. The development thus culminated in a powerful source of sound radiating over 100 watts of acoustical energy.

Remarks

The device failed in its original objective, as might have been expected, for it was concluded that it would be of no military value at ranges greater than 100 meters. The project is of importance because it furnishes concrete evidence of the failure of an idea after proposed as a military weapon. Furthermore, this method of producing intense audio frequency sounds in air may be of some scientific interest.

Sound Waves Kill in Tests by Army. *New York Times.* 30 November 1947 p. 14.

Sound Waves Kill in Tests by Army

Inaudible to Humans, They Fell Mice and Other Pests and Burn Experimenters

WASHINGTON, Nov. 29.—The discovery of sound waves which produce such intense heat that they are lethal to mice and small insects was announced today by the Army.

In tests for the Signal Corps at Penn State College white mice died one minute after exposure to the ultra-sonic waves, which are of such high pitch that they are inaudible to human ears.

Other experiments were performed on the common roach, firebrats, yellow-fever mosquitoes, blow flies, meal worms and caterpillars, and in each case death resulted from the waves' radiation.

Extensive possibilities for pest control were suggested by the experiments, but there was no indication that the discoveries might lead to the use of sound waves as a war weapon.

Nevertheless, it was pointed out that scientists at work on the supersonic project found it difficult to put objects into the sound field or retrieve them without burning their fingers and hands.

They did not expose themselves to the direct beam and wore ear plugs, but even then it was difficult for them to avoid exposure to the radiated sound. Effects ran from loss of a sense of equilibrium to dizziness.

"Supersonics, the science dealing with waves similar to ordinary sound waves but above the audible range, is not expected to serve any immediate domestic uses but offers promise in finding and developing more interesting uses which may be applied to industry," the Army said.

In previous experiments the high-frequency waves have been found useful in detecting defects in metal castings and other materials. They have also be used in emulsifying or colloidizing liquids by dispersion, as is done in producing homogenized milk.

"Experts in the study of supersonics feel that the principle has many unknown qualities that no doubt will be brought out through continued research," the Army explained.

Headquarters for the work are at the Evans Signal Laboratory, Belmar, N. J., and at Penn State College.

[This "new discovery" by the U.S. Army appears to have been directly borrowed from the earlier German and Austrian work, such as that reported in BIOS 1504 and BIOS 1679, down to the specific descriptions of the experiments and their effects and applications. In English at that time, "supersonic" (generally used to describe objects moving faster than the speed of sound) was sometimes used to mean "ultrasonic" (sound frequencies higher than the human ear can detect); this article used both terms. Evans Signal Laboratory was part of the larger Army electronics research complex at Fort Monmouth, New Jersey [Fort Monmouth Historical Office 2008]. It participated in many wartime and postwar missions analyzing German science and technology, and it acquired numerous German scientists and their technologies after the war.]

[Richard Wallauschek's acoustic weapon reported in CIOS XXXII-77 and other wartime acoustic technologies were the forerunners of modern acoustic weapons such as LRAD (Long Range Acoustic Device), shown in Fig. C.118. Even LRAD's specifications are reminiscent of Wallauschek's wartime acoustic weapon. LRAD has a maximum continuous output of 153 dB at 1 meter, with a frequency of 1 kHz and a beam width $\pm 15^o$.

Thus the wartime German work appears directly linked to modern applications of acoustics and ultrasound for imaging, pest control, industry, weapons, etc.]

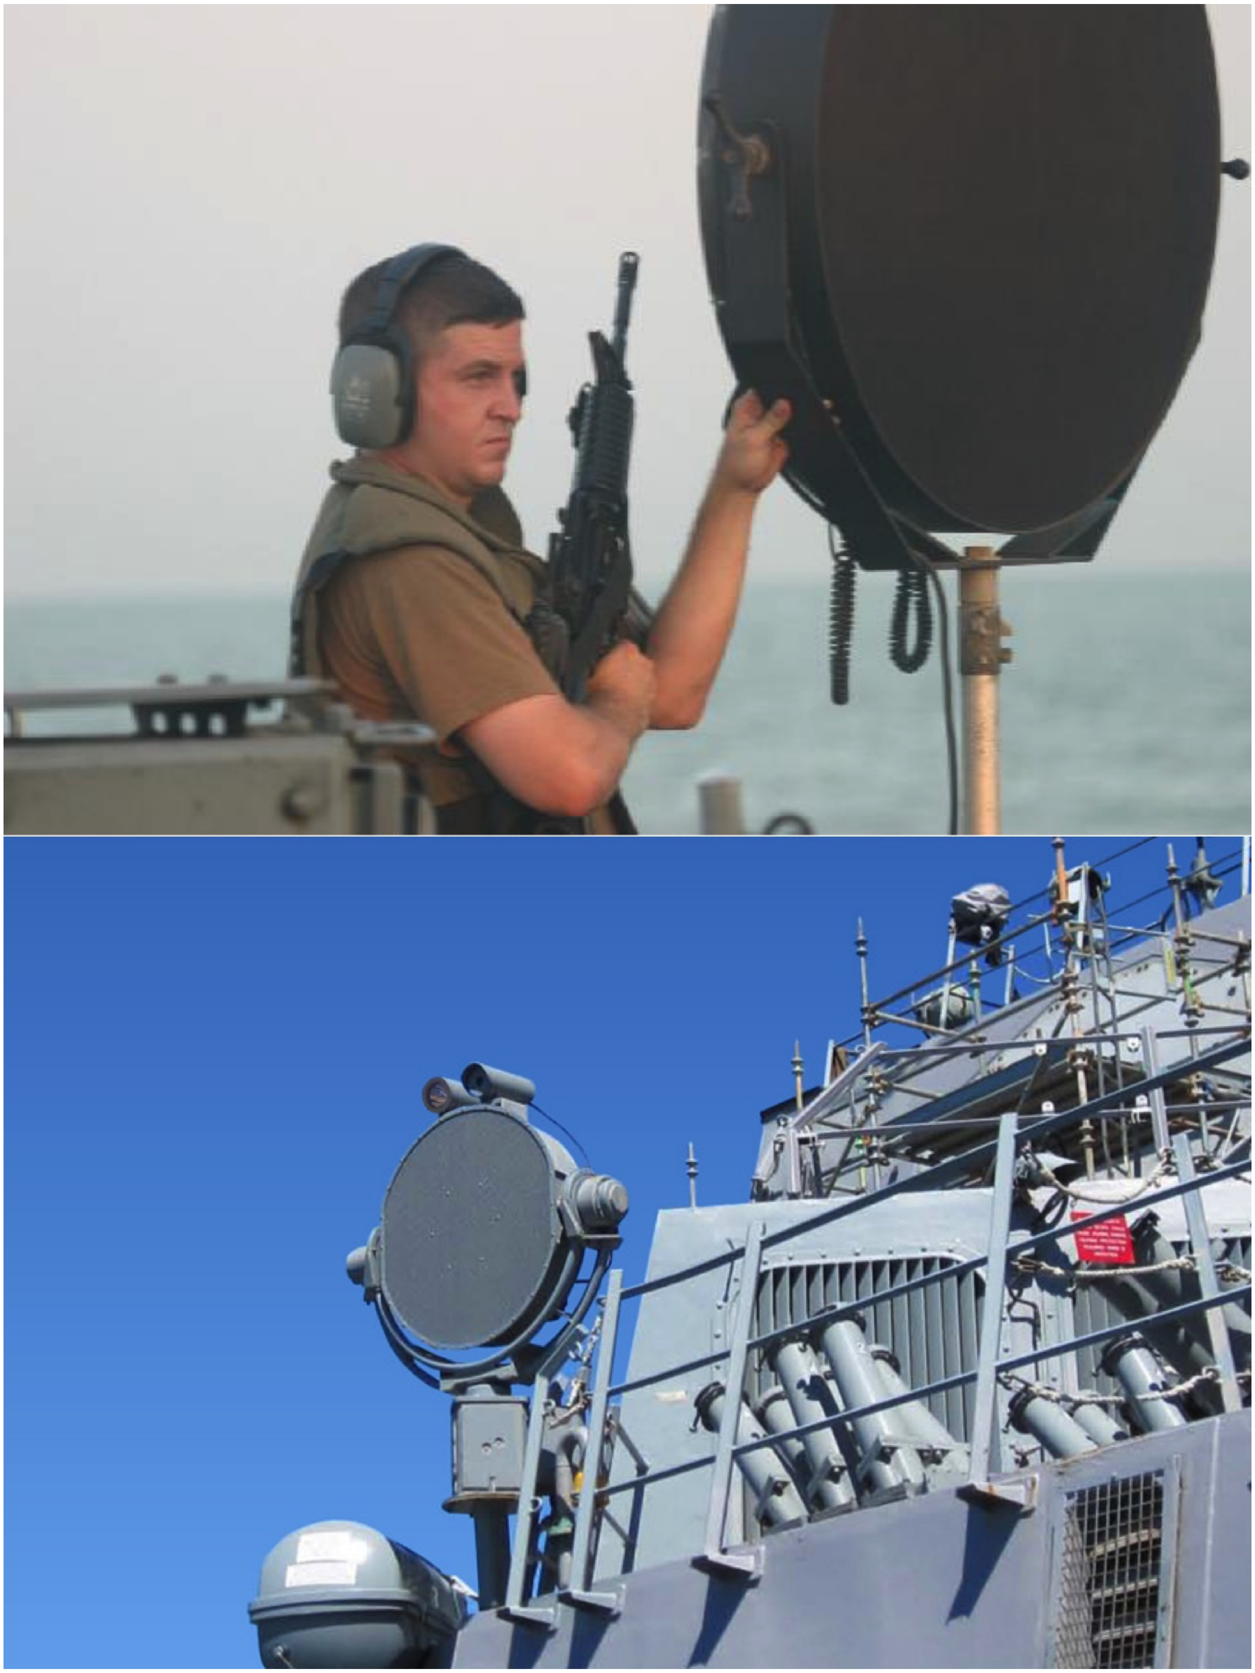

Figure C.118: Modern LRAD (Long Range Acoustic Device) acoustic weapon used by the U.S. Navy and other ships to deter pirates.

C.5 Magnetic Levitation and Electromagnetic Railguns

[Another category of directed energy technologies covers devices that produce large amounts of electromagnetic energy, but then transfer that to a physical object in the form of kinetic energy. Both magnetic levitation systems and railguns employ strong electromagnetic fields and rails to propel and guide an object. In magnetic levitation, such methods are used to support and propel very large objects (such as trains) at relatively low speeds. In electromagnetic railguns, similar methods are used to support and propel very small objects (projectiles) at extremely high speeds. The following documents demonstrate that German-speaking scientists pioneered both of these applications.]

Alfred Zehden. U.S. Patent 782,312. Electric Traction Apparatus. Filed 21 June 1902.

[...] Having thus described my invention, what I claim as new therein, and desire to secure by Letters Patent of the United States of America, is—

1. The combination of a rail-like armature, a traveling field-magnet, and means for neutralizing the magnetic attraction of the latter, substantially as set forth.

2. The combination of a plurality of rail-like armatures, and a plurality of traveling field-magnets arranged to act thereon in opposite directions, substantially as set forth.

3. The combination of a rail-like armature located between the rails, and a traveling field-magnet, said armature being located between the poles of said magnet, so that by the cooperation of these parts the carriage is not only moved forward, but also its weight, namely wheel-pressure, diminished, substantially as set forth.

4. The combination of a rail-like armature provided with openings, and a traveling field-magnet arranged in juxtaposition to said armature, substantially as set forth.

5. The combination of a rail-like armature provided with openings of different breadths, a traveling field-magnet, and means for neutralizing the magnetic attraction of said magnet, substantially as set forth.

6. The combination of a rail-like armature, a traveling field-magnet movable transversely to said armature, means for neutralizing the magnetic attraction of said magnet, and means for guiding said magnet out of contact with said armature, substantially as set forth.

7. The combination of a rail-like armature, reinforced at its outer sides at curves, a traveling field-magnet, and means for neutralizing the magnetic attraction of said magnet, substantially as set forth.

[Alfred Zehden (German, 1876–19??) appears to have been the first scientist or engineer to seriously design magnetically levitated trains. The patent cited above is reproduced in full on the following pages. Zehden filed very similar patents on magnetically levitated trains in several countries at the same time. It is not clear how far he actually got with corresponding experiments for this technology.]

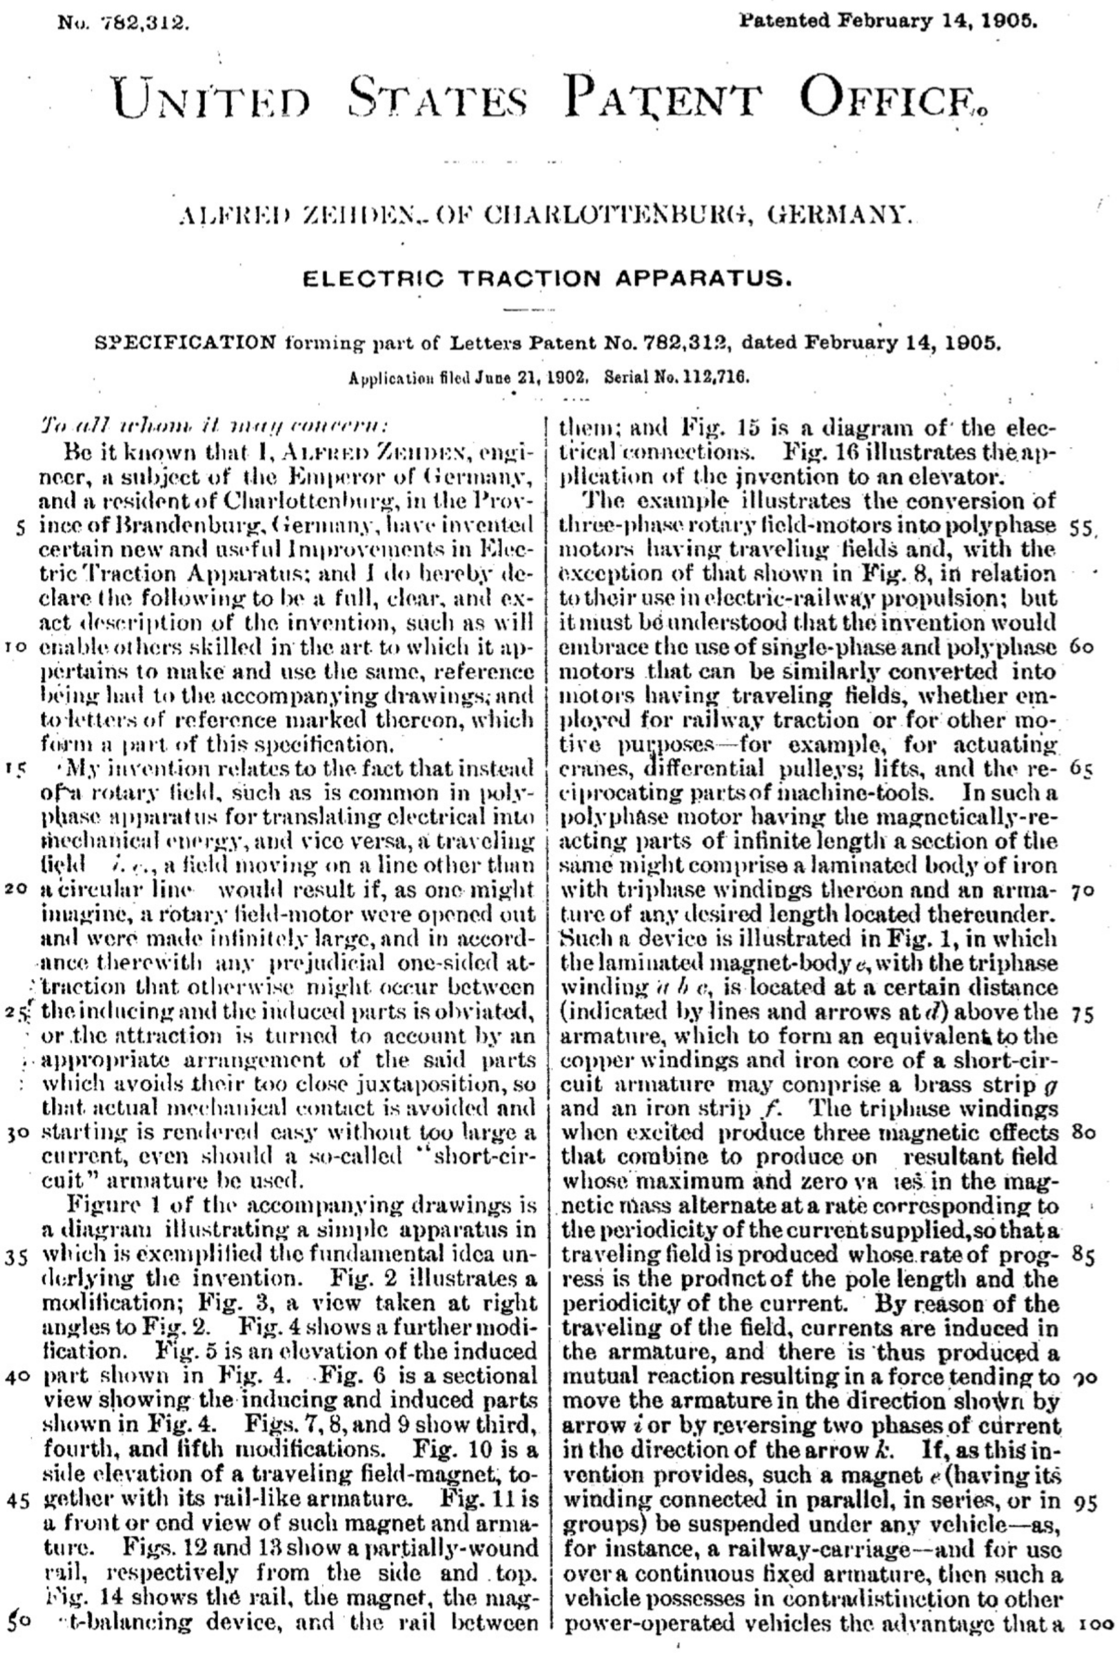
Figure C.122: U.S. patent 782,312 on magnetically levitated trains, filed by Alfred Zehden in 1902.



No. 782,312. **Patented February 14, 1905.**

UNITED STATES PATENT OFFICE.

ALFRED ZEHDEN, OF CHARLOTTENBURG, GERMANY.

ELECTRIC TRACTION APPARATUS.

SPECIFICATION forming part of Letters Patent No. 782,312, dated February 14, 1905.

Application filed June 21, 1902. Serial No. 112,716.

To all whom it may concern:

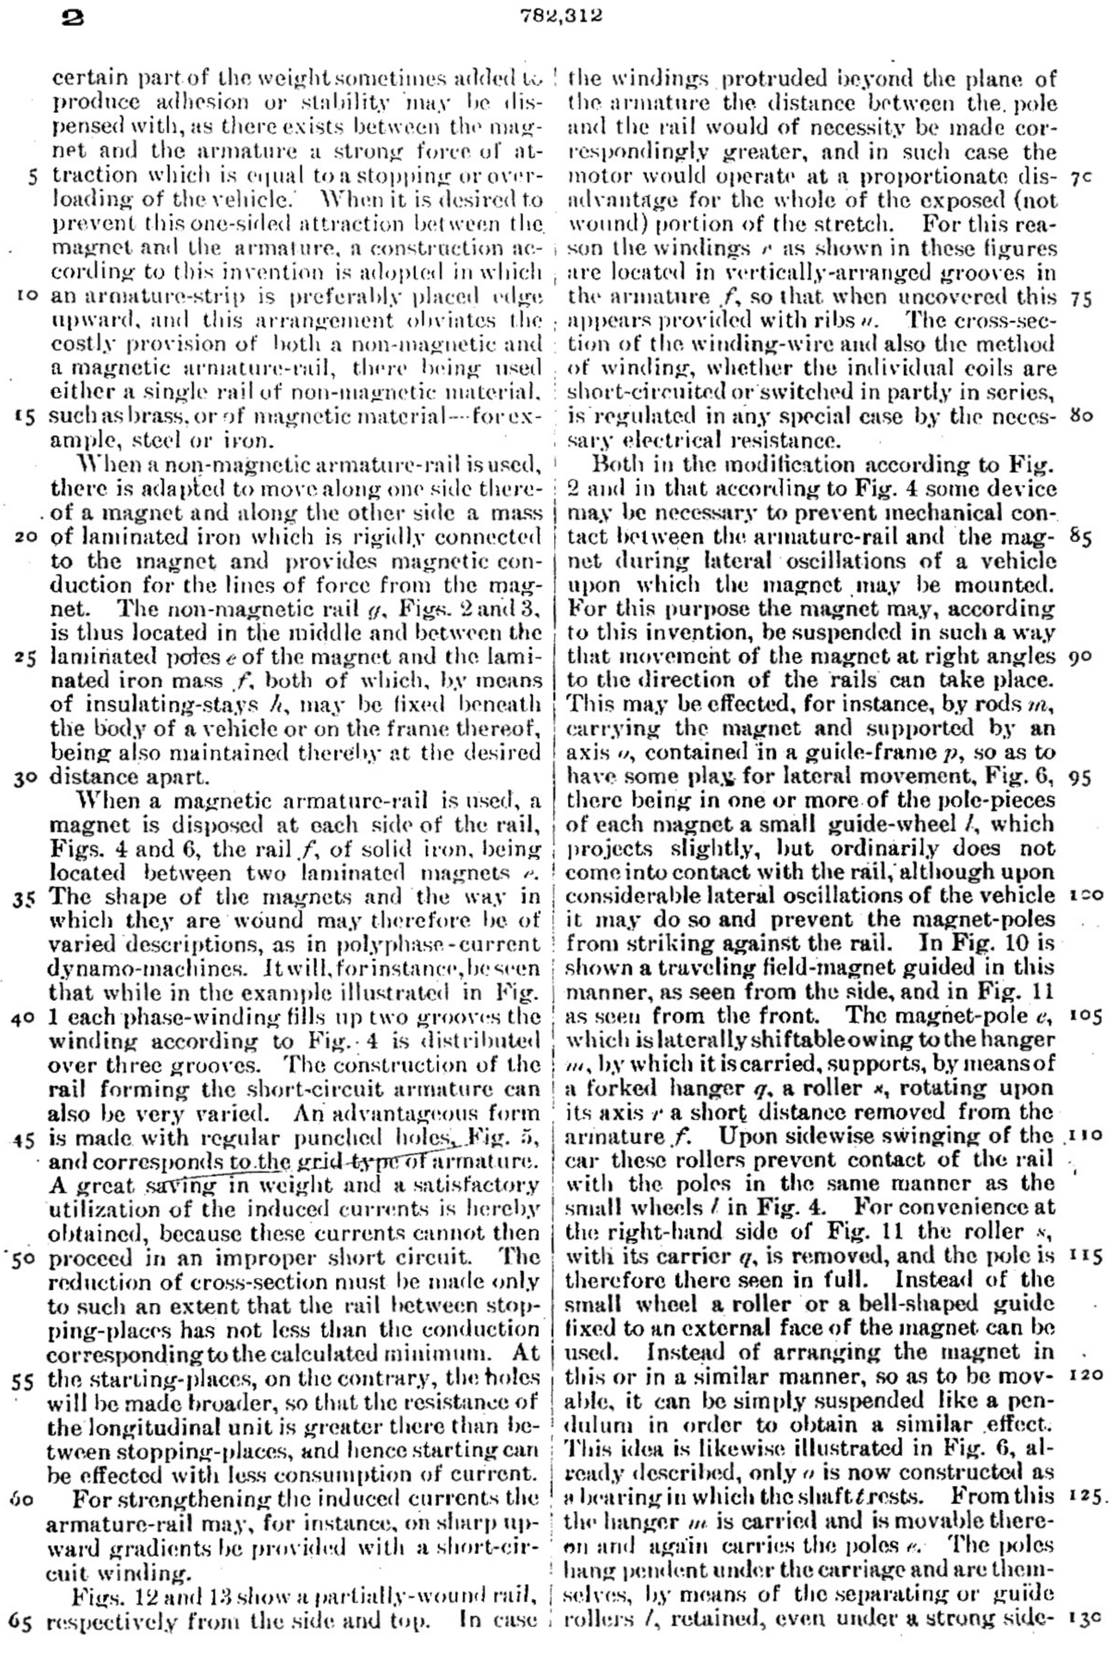
Be it known that I, Alfred Zehden, engineer, a subject of the Emperor of Germany, and a resident of Charlottenburg, in the Province of Brandenburg, Germany, have invented certain new and useful Improvements in Electric Traction Apparatus; and I do hereby declare the following to be a full, clear, and exact description of the invention, such as will enable others skilled in the art to which it appertains to make and use the same, reference being had to the accompanying drawings, and to letters of reference marked thereon, which form a part of this specification.

My invention relates to the fact that instead of a rotary field, such as is common in polyphase apparatus for translating electrical into mechanical energy, and vice versa, a traveling field—*i. e.*, a field moving on a line other than a circular line—would result if, as one might imagine, a rotary field-motor were opened out and were made infinitely large, and in accordance therewith any prejudicial one-sided attraction that otherwise might occur between the inducing and the induced parts is obviated, or the attraction is turned to account by an appropriate arrangement of the said parts which avoids their too close juxtaposition, so that actual mechanical contact is avoided and starting is rendered easy without too large a current, even should a so-called "short-circuit" armature be used.

Figure 1 of the accompanying drawings is a diagram illustrating a simple apparatus in which is exemplified the fundamental idea underlying the invention. Fig. 2 illustrates a modification; Fig. 3, a view taken at right angles to Fig. 2. Fig. 4 shows a further modification. Fig. 5 is an elevation of the induced part shown in Fig. 4. Fig. 6 is a sectional view showing the inducing and induced parts shown in Fig. 4. Figs. 7, 8, and 9 show third, fourth, and fifth modifications. Fig. 10 is a side elevation of a traveling field-magnet, together with its rail-like armature. Fig. 11 is a front or end view of such magnet and armature. Figs. 12 and 13 show a partially-wound rail, respectively from the side and top. Fig. 14 shows the rail, the magnet, the magnet-balancing device, and the rail between them; and Fig. 15 is a diagram of the electrical connections. Fig. 16 illustrates the application of the invention to an elevator.

The example illustrates the conversion of three-phase rotary field-motors into polyphase motors having traveling fields and, with the exception of that shown in Fig. 8, in relation to their use in electric-railway propulsion; but it must be understood that the invention would embrace the use of single-phase and polyphase motors that can be similarly converted into motors having traveling fields, whether employed for railway traction or for other motive purposes—for example, for actuating cranes, differential pulleys, lifts, and the reciprocating parts of machine-tools. In such a polyphase motor having the magnetically-reacting parts of infinite length a section of the same might comprise a laminated body of iron with triphase windings thereon and an armature of any desired length located thereunder. Such a device is illustrated in Fig. 1, in which the laminated magnet-body *e*, with the triphase winding *a b c*, is located at a certain distance (indicated by lines and arrows at *d*) above the armature, which to form an equivalent to the copper windings and iron core of a short-circuit armature may comprise a brass strip *g* and an iron strip *f*. The triphase windings when excited produce three magnetic effects that combine to produce one resultant field whose maximum and zero values in the magnetic mass alternate at a rate corresponding to the periodicity of the current supplied, so that a traveling field is produced whose rate of progress is the prodnct of the pole length and the periodicity of the current. By reason of the traveling of the field, currents are induced in the armature, and there is thus produced a mutual reaction resulting in a force tending to move the armature in the direction shown by arrow *i* or by reversing two phases of current in the direction of the arrow *k*. If, as this invention provides, such a magnet *e* (having its winding connected in parallel, in series, or in groups) be suspended under any vehicle—as, for instance, a railway-carriage—and for use over a continuous fixed armature, then such a vehicle possesses in contradistinction to other power-operated vehicles the advantage that a

Figure C.123: U.S. patent 782,312 on magnetically levitated trains, filed by Alfred Zehden in 1902.



2

782,312

certain part of the weight sometimes added to produce adhesion or stability may be dispensed with, as there exists between the magnet and the armature a strong force of attraction which is equal to a stopping or overloading of the vehicle. When it is desired to prevent this one-sided attraction between the magnet and the armature, a construction according to this invention is adopted in which an armature-strip is preferably placed edge upward, and this arrangement obviates the costly provision of both a non-magnetic and a magnetic armature-rail, there being used either a single rail of non-magnetic material, such as brass, or of magnetic material—for example, steel or iron.

When a non-magnetic armature-rail is used, there is adapted to move along one side thereof a magnet and along the other side a mass of laminated iron which is rigidly connected to the magnet and provides magnetic conduction for the lines of force from the magnet. The non-magnetic rail *g*, Figs. 2 and 3, is thus located in the middle and between the laminated poles *e* of the magnet and the laminated iron mass *f*, both of which, by means of insulating-stays *h*, may be fixed beneath the body of a vehicle or on the frame thereof, being also maintained thereby at the desired distance apart.

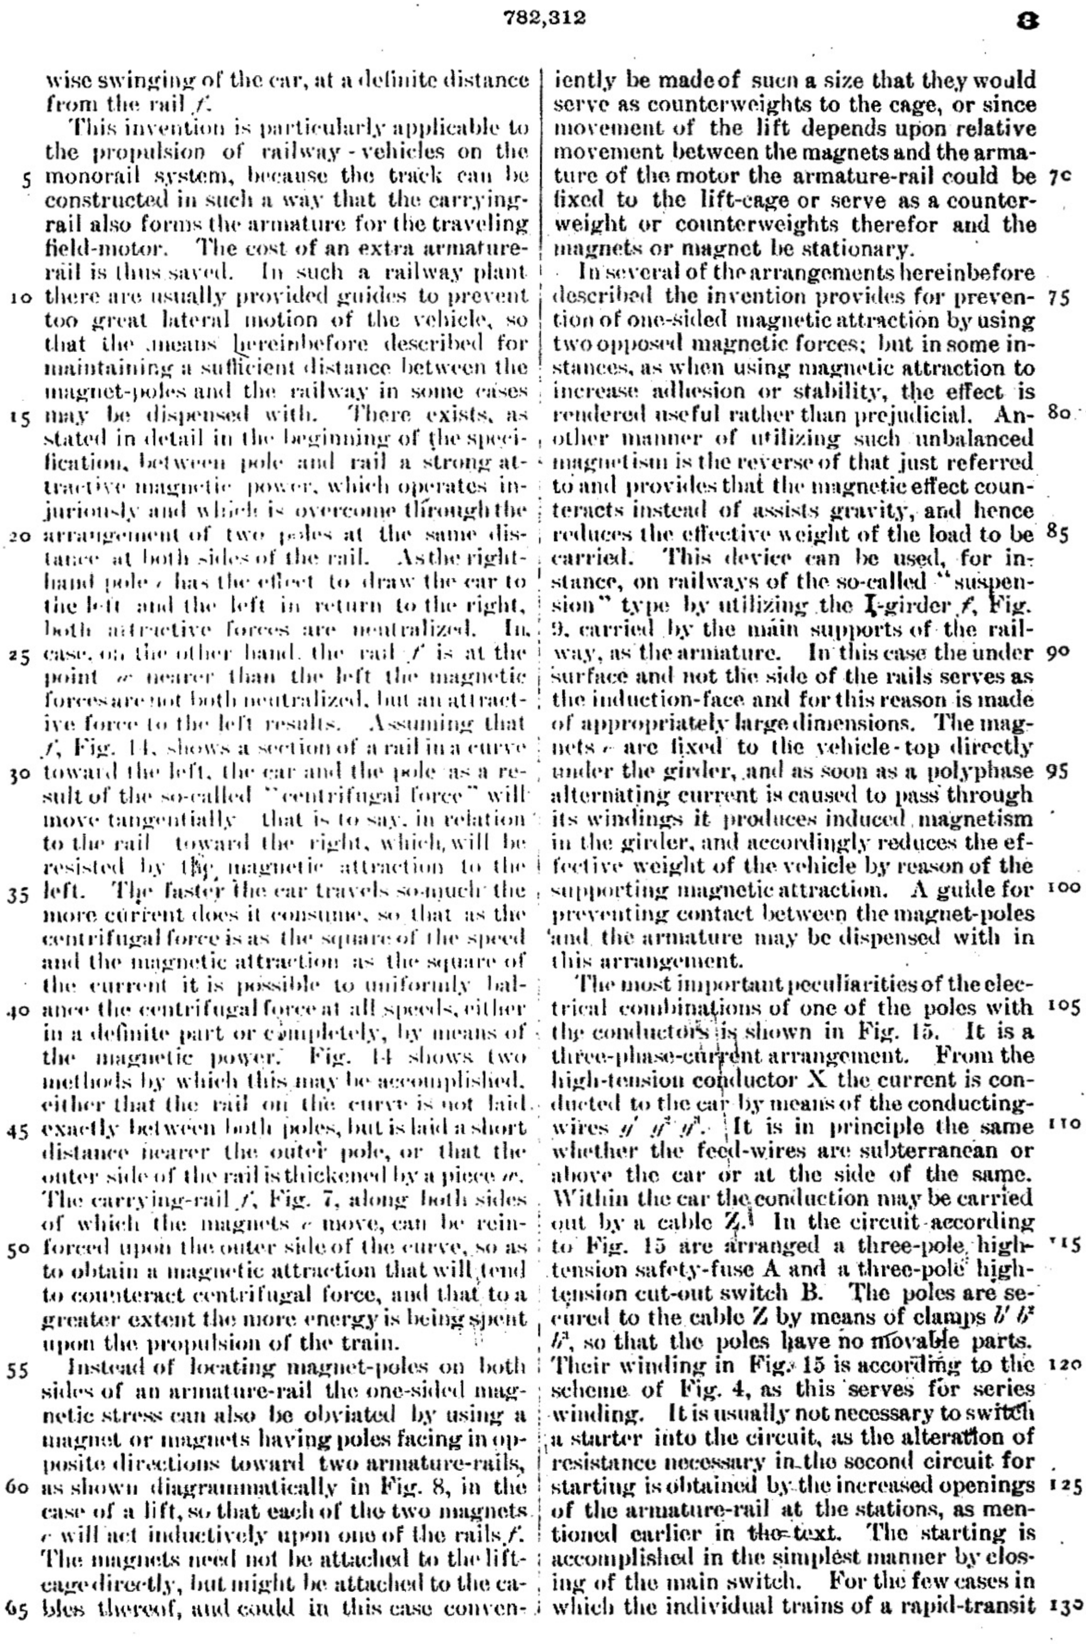
When a magnetic armature-rail is used, a magnet is disposed at each side of the rail, Figs. 4 and 6, the rail *f*, of solid iron, being located between two laminated magnets *e*. The shape of the magnets and the way in which they are wound may therefore be of varied descriptions, as in polyphase-current dynamo-machines. It will, for instance, be seen that while in the example illustrated in Fig. 1 each phase-winding fills up two grooves the winding according to Fig. 4 is distributed over three grooves. The construction of the rail forming the short-circuit armature can also be very varied. An advantageous form is made with regular punched holes, Fig. 5, and corresponds to the grid type of armature. A great saving in weight and a satisfactory utilization of the induced currents is hereby obtained, because these currents cannot then proceed in an improper short circuit. The reduction of cross-section must be made only to such an extent that the rail between stopping-places has not less than the conduction corresponding to the calculated minimum. At the starting-places, on the contrary, the holes will be made broader, so that the resistance of the longitudinal unit is greater there than between stopping-places, and hence starting can be effected with less consumption of current.

For strengthening the induced currents the armature-rail may, for instance, on sharp upward gradients be provided with a short-circuit winding.

Figs. 12 and 13 show a partially-wound rail, respectively from the side and top. In case the windings protruded beyond the plane of the armature the distance between the pole and the rail would of necessity be made correspondingly greater, and in such case the motor would operate at a proportionate disadvantage for the whole of the exposed (not wound) portion of the stretch. For this reason the windings *e* as shown in these figures are located in vertically-arranged grooves in the armature *f*, so that when uncovered this appears provided with ribs *u*. The cross-section of the winding-wire and also the method of winding, whether the individual coils are short-circuited or switched in partly in series, is regulated in any special case by the necessary electrical resistance.

Both in the modification according to Fig. 2 and in that according to Fig. 4 some device may be necessary to prevent mechanical contact between the armature-rail and the magnet during lateral oscillations of a vehicle upon which the magnet may be mounted. For this purpose the magnet may, according to this invention, be suspended in such a way that movement of the magnet at right angles to the direction of the rails can take place. This may be effected, for instance, by rods *m*, carrying the magnet and supported by an axis *o*, contained in a guide-frame *p*, so as to have some play for lateral movement, Fig. 6, there being in one or more of the pole-pieces of each magnet a small guide-wheel *l*, which projects slightly, but ordinarily does not come into contact with the rail, although upon considerable lateral oscillations of the vehicle it may do so and prevent the magnet-poles from striking against the rail. In Fig. 10 is shown a traveling field-magnet guided in this manner, as seen from the side, and in Fig. 11 as seen from the front. The magnet-pole *e*, which is laterally shiftable owing to the hanger *m*, by which it is carried, supports, by means of a forked hanger *q*, a roller *x*, rotating upon its axis *r* a short distance removed from the armature *f*. Upon sidewise swinging of the car these rollers prevent contact of the rail with the poles in the same manner as the small wheels *l* in Fig. 4. For convenience at the right-hand side of Fig. 11 the roller *s*, with its carrier *q*, is removed, and the pole is therefore there seen in full. Instead of the small wheel a roller or a bell-shaped guide fixed to an external face of the magnet can be used. Instead of arranging the magnet in this or in a similar manner, so as to be movable, it can be simply suspended like a pendulum in order to obtain a similar effect. This idea is likewise illustrated in Fig. 6, already described, only *o* is now constructed as a bearing in which the shaft *t* rests. From this the hanger *m* is carried and is movable thereon and again carries the poles *e*. The poles hang pendent under the carriage and are themselves, by means of the separating or guide rollers *l*, retained, even under a strong side-

Figure C.124: U.S. patent 782,312 on magnetically levitated trains, filed by Alfred Zehden in 1902.



782,312 3

wise swinging of the car, at a definite distance from the rail *f*.

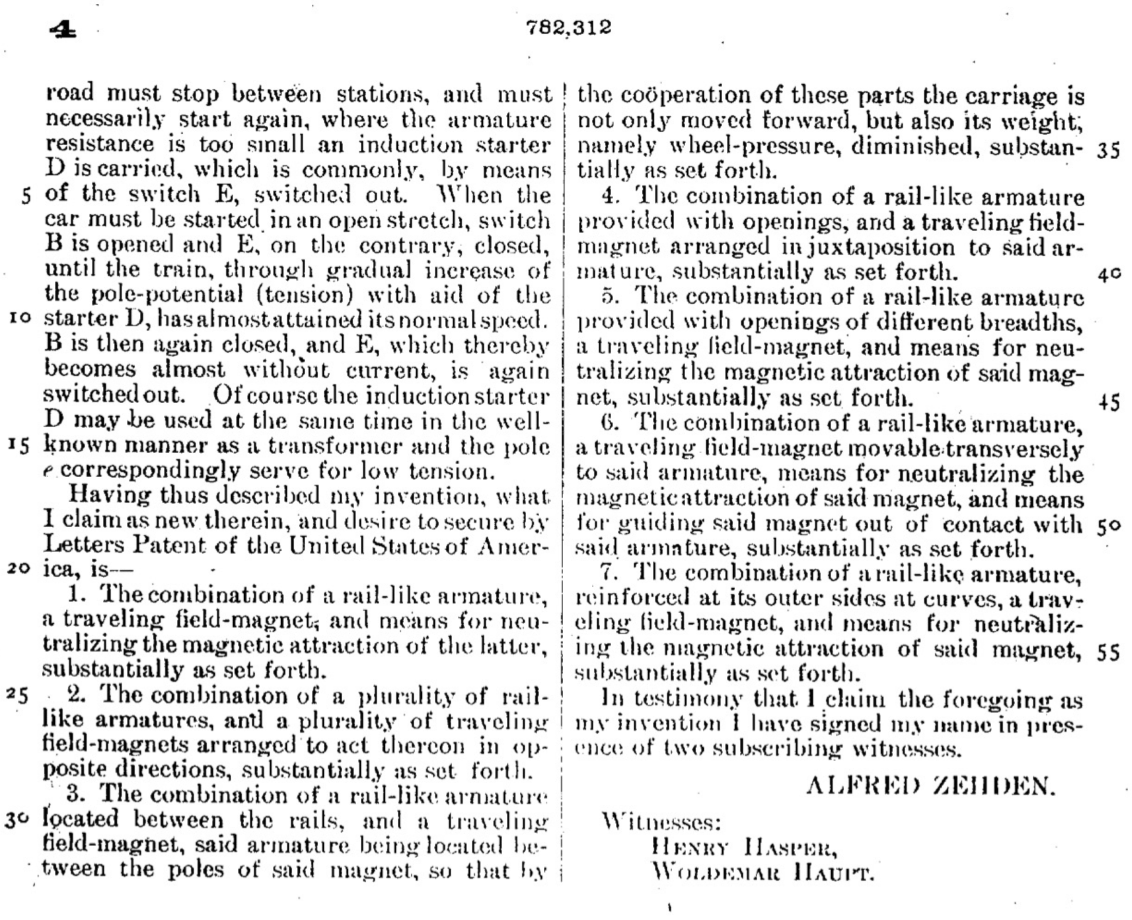
This invention is particularly applicable to the propulsion of railway-vehicles on the monorail system, because the track can be constructed in such a way that the carrying-rail also forms the armature for the traveling field-motor. The cost of an extra armature-rail is thus saved. In such a railway plant there are usually provided guides to prevent too great lateral motion of the vehicle, so that the means hereinbefore described for maintaining a sufficient distance between the magnet-poles and the railway in some cases may be dispensed with. There exists, as stated in detail in the beginning of the specification, between pole and rail a strong attractive magnetic power, which operates injuriously and which is overcome through the arrangement of two poles at the same distance at both sides of the rail. As the right-hand pole *e* has the effect to draw the car to the left and the left in return to the right, both attractive forces are neutralized. In case, on the other hand, the rail *f* is at the point *w* nearer than the left the magnetic forces are not both neutralized, but an attractive force to the left results. Assuming that *f*, Fig. 14, shows a section of a rail in a curve toward the left, the car and the pole as a result of the so-called "centrifugal force" will move tangentially that is to say, in relation to the rail toward the right, which, will be resisted by the magnetic attraction to the left. The faster the car travels so much the more current does it consume, so that as the centrifugal force is as the square of the speed and the magnetic attraction as the square of the current it is possible to uniformly balance the centrifugal force at all speeds, either in a definite part or completely, by means of the magnetic power. Fig. 14 shows two methods by which this may be accomplished, either that the rail on the curve is not laid exactly between both poles, but is laid a short distance nearer the outer pole, or that the outer side of the rail is thickened by a piece *w*. The carrying-rail *f*, Fig. 7, along both sides of which the magnets *e* move, can be reinforced upon the outer side of the curve, so as to obtain a magnetic attraction that will tend to counteract centrifugal force, and that to a greater extent the more energy is being spent upon the propulsion of the train.

Instead of locating magnet-poles on both sides of an armature-rail the one-sided magnetic stress can also be obviated by using a magnet or magnets having poles facing in opposite directions toward two armature-rails, as shown diagrammatically in Fig. 8, in the case of a lift, so that each of the two magnets *e* will act inductively upon one of the rails *f*. The magnets need not be attached to the lift-cage directly, but might be attached to the cables thereof, and could in this case conveniently be made of such a size that they would serve as counterweights to the cage, or since movement of the lift depends upon relative movement between the magnets and the armature of the motor the armature-rail could be fixed to the lift-cage or serve as a counterweight or counterweights therefor and the magnets or magnet be stationary.

In several of the arrangements hereinbefore described the invention provides for prevention of one-sided magnetic attraction by using two opposed magnetic forces; but in some instances, as when using magnetic attraction to increase adhesion or stability, the effect is rendered useful rather than prejudicial. Another manner of utilizing such unbalanced magnetism is the reverse of that just referred to and provides that the magnetic effect counteracts instead of assists gravity, and hence reduces the effective weight of the load to be carried. This device can be used, for instance, on railways of the so-called "suspension" type by utilizing the I-girder *f*, Fig. 9, carried by the main supports of the railway, as the armature. In this case the under surface and not the side of the rails serves as the induction-face and for this reason is made of appropriately large dimensions. The magnets *e* are fixed to the vehicle-top directly under the girder, and as soon as a polyphase alternating current is caused to pass through its windings it produces induced magnetism in the girder, and accordingly reduces the effective weight of the vehicle by reason of the supporting magnetic attraction. A guide for preventing contact between the magnet-poles and the armature may be dispensed with in this arrangement.

The most important peculiarities of the electrical combinations of one of the poles with the conductors is shown in Fig. 15. It is a three-phase-current arrangement. From the high-tension conductor X the current is conducted to the car by means of the conducting-wires g' g^2 g^3. It is in principle the same whether the feed-wires are subterranean or above the car or at the side of the same. Within the car the conduction may be carried out by a cable Z. In the circuit according to Fig. 15 are arranged a three-pole high-tension safety-fuse A and a three-pole high-tension cut-out switch B. The poles are secured to the cable Z by means of clamps b' b^2 b^3, so that the poles have no movable parts. Their winding in Fig. 15 is according to the scheme of Fig. 4, as this serves for series winding. It is usually not necessary to switch a starter into the circuit, as the alteration of resistance necessary in the second circuit for starting is obtained by the increased openings of the armature-rail at the stations, as mentioned earlier in the text. The starting is accomplished in the simplest manner by closing of the main switch. For the few cases in which the individual trains of a rapid-transit

Figure C.125: U.S. patent 782,312 on magnetically levitated trains, filed by Alfred Zehden in 1902.



4 782,312

road must stop between stations, and must necessarily start again, where the armature resistance is too small an induction starter D is carried, which is commonly, by means of the switch E, switched out. When the car must be started in an open stretch, switch B is opened and E, on the contrary, closed, until the train, through gradual increase of the pole-potential (tension) with aid of the starter D, has almost attained its normal speed. B is then again closed, and E, which thereby becomes almost without current, is again switched out. Of course the induction starter D may be used at the same time in the well-known manner as a transformer and the pole correspondingly serve for low tension.

Having thus described my invention, what I claim as new therein, and desire to secure by Letters Patent of the United States of America, is—

1. The combination of a rail-like armature, a traveling field-magnet, and means for neutralizing the magnetic attraction of the latter, substantially as set forth.

2. The combination of a plurality of rail-like armatures, and a plurality of traveling field-magnets arranged to act thereon in opposite directions, substantially as set forth.

3. The combination of a rail-like armature located between the rails, and a traveling field-magnet, said armature being located between the poles of said magnet, so that by the coöperation of these parts the carriage is not only moved forward, but also its weight, namely wheel-pressure, diminished, substantially as set forth.

4. The combination of a rail-like armature provided with openings, and a traveling field-magnet arranged in juxtaposition to said armature, substantially as set forth.

5. The combination of a rail-like armature provided with openings of different breadths, a traveling field-magnet, and means for neutralizing the magnetic attraction of said magnet, substantially as set forth.

6. The combination of a rail-like armature, a traveling field-magnet movable transversely to said armature, means for neutralizing the magnetic attraction of said magnet, and means for guiding said magnet out of contact with said armature, substantially as set forth.

7. The combination of a rail-like armature, reinforced at its outer sides at curves, a traveling field-magnet, and means for neutralizing the magnetic attraction of said magnet, substantially as set forth.

In testimony that I claim the foregoing as my invention I have signed my name in presence of two subscribing witnesses.

ALFRED ZEHDEN.

Hermann Kemper. Patent DE643316. Schwebebahn mit raederlosen Fahrzeugen, die an eisernen Fahrschienen mittels magnetischer Felder schwebend entlang gefuehrt werden. [Suspension Railway with Vehicles without Wheels, which Are Guided along Iron Rails by Means of Magnetic Fields.] Filed 11 August 1934.

[...] PATENTANSPRUCH:

Schwebebahn mit räderlosen Fahrzeugen, die an eisernen Fahrschienen mittels magnetischer, in zwischen den Schienen und an den Fahrzeugen verteilt befestigten Elektromagneten erzeugter Felder schwebend entlang geführt werden, dadurch gekennzeichnet, daß die Regelung der magnetischen Felder durch Abstandssteuerorgane geschieht, die an den Schwebewagen (3) gegenüber den Führungsschienen (2) räumlich nahe den von ihnen zu steuernden Elektromagneten befestigt sind. Die Abstandssteuerorgane (Abb. 4, 5) sind mechanisch unveränderliche, jedoch in ihrem elektrischen Widerstand durch den Abstand von den Schienen beeinflußte elektrische oder magnetische Anordnungen (z. B. Kondensatoren 8, 9 oder Drosselspulen 10, 11) und werden in elektrische Stromkreise eingeschaltet, wobei sie an ihren Polen Spannungen erzeugen, die sich mit dem Abstand von den Führungsschienen unverzüglich ändern. Diese Spannungen werden, soweit erforderlich, in ebenfalls trägheitsarmen Schaltungen verstärkt und, gegebenenfalls gleichgerichtet, elektrischen Röhren zu deren Steuerung zugeführt (Abb. 6). Der Sinn und die Größe dieser Steuerspannungen ist so zu wählen, daß durch die von den Röhren den Elektromagneten zugeleiteten Ströme magnetische Zugkräfte erzeugt werden, die der Schwerkraft das Gleichgewicht halten, wenn der Abstand der Fahrzeuge von den Schienen das vorgeschriebene Maß hat, die dagegen die Schwerkraft übersteigen, wenn der Abstand zu groß wird, sie endlich unterschreiten, wenn der Abstand unter das Sollmaß herabsinkt.

[...] PATENT CLAIM:

Suspension railway with wheelless vehicles which are guided along iron rails in a floating manner by means of magnetic fields generated in electromagnets fixed in a distributed manner between the rails and on the vehicles, characterized in that the magnetic fields are controlled by distance control elements which are fixed to the suspension wagons (3) relative to the guide rails (2) spatially close to the electromagnets to be controlled by them. The distance control devices (Figs. 4, 5) are electrical or magnetic arrangements (e.g. capacitors 8, 9 or generators 10, 11) which are mechanically fixed but whose electrical resistance is influenced by the distance from the rails, and are connected to electrical circuits, generating voltages at their poles which change immediately with the distance from the guide rails. If necessary, these voltages are amplified in circuits with low inertia and, if necessary in the same direction, supplied to electrical tubes for their control (Fig. 6). The sense and magnitude of these control voltages shall be such that the currents supplied by the tubes to the electromagnets generate magnetic tractive forces which maintain the equilibrium of gravity when the distance of the vehicles from the rails is greater than the prescribed value but which exceed gravity when the distance becomes too great and finally fall below it when the distance falls below the required value.

[Hermann Kemper (German, 1892–1977) built on Alfred Zehden's earlier work on magnetic levitation for trains. His complete patent is reproduced on the following pages. It is not clear how far Kemper got with corresponding experiments for this technology.]

Dipl.-Ing. Hermann Kemper in Nortrup

Schwebebahn mit räderlosen Fahrzeugen, die an eisernen Fahrschienen mittels magnetischer Felder schwebend entlang geführt werden

Patentiert im Deutschen Reiche vom 11. August 1934 ab

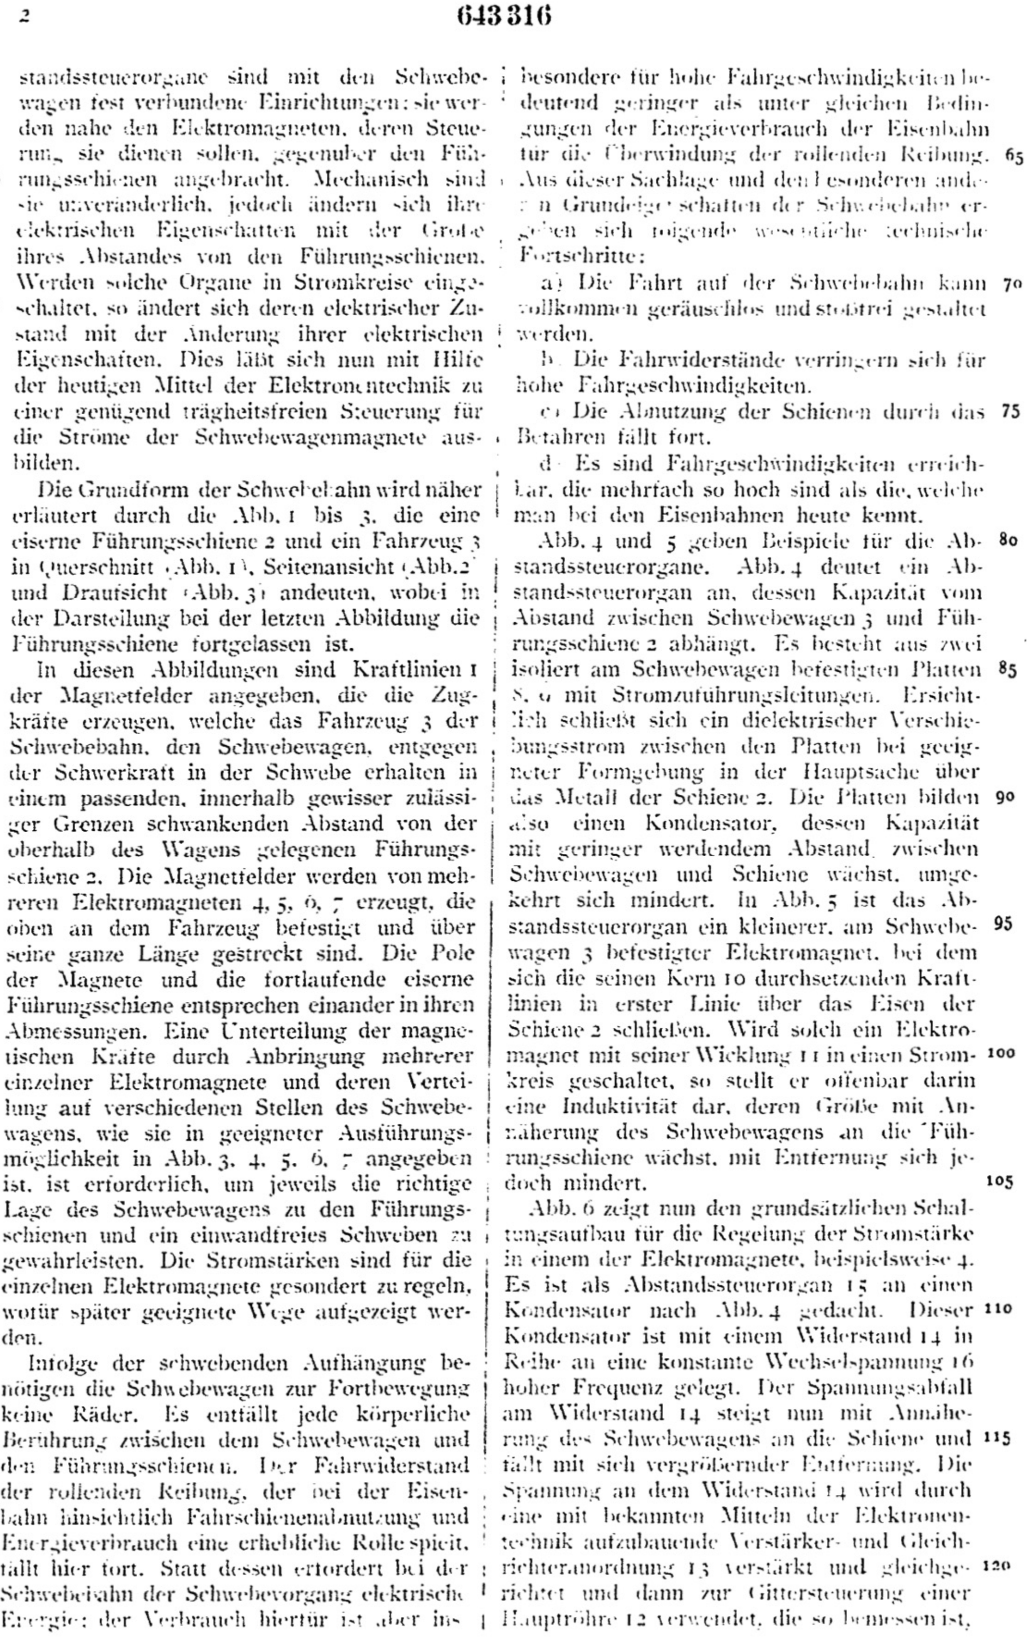
Die Erfindung löst die Aufgabe, Körper mit Hilfe elektromagnetischer Kräfte entgegen der Erdschwerkraft in der Schwebe zu halten. Sie bringt weiter unter Anwendung der gefundenen Lösung die Grundlagen für ein neuartiges Verkehrsmittel, die Schwebebahn. Die Schwebebahn ist eine Schienenbahn für Menschen- und Güterbeförderung, bei der die räderlosen Fahrzeuge eisernen Schienen entlang schwebend geführt werden.

Es ist schon früher versucht worden, die Aufgaben zu lösen, die eine Schwebebahn stellt. Einmal sollten bei den bisher bekannten Anordnungen dazu die abstoßenden Kräfte dienen, die zwischen einem Elektromagnet und elektrischen Leitern auftreten, wenn das Feld des Magnets Änderungen unterworfen wird und dann Ströme in den Leitern erregt. Zum anderenmal sollten, genau wie bei der Erfindung, die magnetischen Zugkräfte zwischen Elektromagneten und eisernen Schienen benutzt werden. Die zum Schweben erforderliche Stromregelung sollte bei der letztgenannten bekannten Anordnung erreicht werden durch Vorrichtungen, die, beeinflußt vom Abstand zwischen Fahrzeug und Schiene, mechanisch die Stärke des die Elektromagneten durchfließenden Stromes verändern. Es ist nicht bekanntgeworden, daß eine Verwirklichung der älteren Erfindungsgedanken auch nur in Versuchen gelungen ist, geschweige denn daß eine Beförderungseinrichtung auf Grund derselben je ausgeführt worden wäre. Es erscheint dies auch kaum möglich. Der Lösungsversuch, durch Erzeugung magnetisch abstoßender Kräfte größere Fahrzeuge im Schweben zu erhalten, muß an dem dafür erforderlichen Aufwand scheitern; dieser ist der Natur der Dinge entsprechend um ein Mehrfaches größer als bei Verwendung magnetisch anziehender Kräfte. Verwendet man hingegen letztere, so erscheint der Gedanke undurchführbar, eine geeignete Stromregelung durch mechanische Vorrichtungen zu erreichen, weil sich hierfür kaum praktisch brauchbare Formen entwickeln lassen dürften, die gleichzeitig eine ausreichende Regelgeschwindigkeit aufweisen. Die Beherrschung der Geschwindigkeit für die Stromregelung ist einwandfrei nur möglich unter Verwendung der erst nach der Zeit der älteren Erfindungen zur Ausbildung gelangten Mittel der Elektronentechnik.

Körper mit elektromagnetischen Kräften schwebend aufzuhängen, ist trotz des bisherigen Standes der Technik eine in den Kreisen der Technik und der Öffentlichkeit ganz unbeachtete Aufgabe geblieben. Sie wird hier neu aufgegriffen. Im vorliegenden Patent und den späteren Zusatzerfindungen werden die Mittel und Wege zu ihrer befriedigenden Lösung und fruchtbringenden Verwertung aufgezeigt.

Die Erfindung geht, um zu einer Stromsteuerung zu kommen, die das Schweben einwandfrei ermöglicht, von Regelorganen, Abstandssteuerorganen, eigener Art aus. Die Ab-

Figure C.127: German patent DE643316 on magnetically levitated trains, filed by Hermann Kemper in 1934.



2

643 316

standssteuerorgane sind mit den Schwebewagen fest verbundene Einrichtungen; sie werden nahe den Elektromagneten, deren Steuerung sie dienen sollen, gegenüber den Führungsschienen angebracht. Mechanisch sind sie unveränderlich, jedoch ändern sich ihre elektrischen Eigenschaften mit der Größe ihres Abstandes von den Führungsschienen. Werden solche Organe in Stromkreise eingeschaltet, so ändert sich deren elektrischer Zustand mit der Änderung ihrer elektrischen Eigenschaften. Dies läßt sich nun mit Hilfe der heutigen Mittel der Elektronentechnik zu einer genügend trägheitsfreien Steuerung für die Ströme der Schwebewagenmagnete ausbilden.

Die Grundform der Schwebebahn wird näher erläutert durch die Abb. 1 bis 3, die eine eiserne Führungsschiene 2 und ein Fahrzeug 3 in Querschnitt (Abb. 1), Seitenansicht (Abb. 2) und Draufsicht (Abb. 3) andeuten, wobei in der Darstellung bei der letzten Abbildung die Führungsschiene fortgelassen ist.

In diesen Abbildungen sind Kraftlinien 1 der Magnetfelder angegeben, die die Zugkräfte erzeugen, welche das Fahrzeug 3 der Schwebebahn, den Schwebewagen, entgegen der Schwerkraft in der Schwebe erhalten in einem passenden, innerhalb gewisser zulässiger Grenzen schwankenden Abstand von der oberhalb des Wagens gelegenen Führungsschiene 2. Die Magnetfelder werden von mehreren Elektromagneten 4, 5, 6, 7 erzeugt, die oben an dem Fahrzeug befestigt und über seine ganze Länge gestreckt sind. Die Pole der Magnete und die fortlaufende eiserne Führungsschiene entsprechen einander in ihren Abmessungen. Eine Unterteilung der magnetischen Kräfte durch Anbringung mehrerer einzelner Elektromagnete und deren Verteilung auf verschiedenen Stellen des Schwebewagens, wie sie in geeigneter Ausführungsmöglichkeit in Abb. 3, 4, 5, 6, 7 angegeben ist, ist erforderlich, um jeweils die richtige Lage des Schwebewagens zu den Führungsschienen und ein einwandfreies Schweben zu gewährleisten. Die Stromstärken sind für die einzelnen Elektromagnete gesondert zu regeln, wofür später geeignete Wege aufgezeigt werden.

Infolge der schwebenden Aufhängung benötigen die Schwebewagen zur Fortbewegung keine Räder. Es entfällt jede körperliche Berührung zwischen dem Schwebewagen und den Führungsschienen. Der Fahrwiderstand der rollenden Reibung, der bei der Eisenbahn hinsichtlich Fahrschienenabnutzung und Energieverbrauch eine erhebliche Rolle spielt, fällt hier fort. Statt dessen erfordert bei der Schwebebahn der Schwebevorgang elektrische Energie; der Verbrauch hierfür ist aber insbesondere für hohe Fahrgeschwindigkeiten bedeutend geringer als unter gleichen Bedingungen der Energieverbrauch der Eisenbahn für die Überwindung der rollenden Reibung. Aus dieser Sachlage und den besonderen anderen Grundeigenschaften der Schwebebahn ergeben sich folgende wesentliche technische Fortschritte:

a) Die Fahrt auf der Schwebebahn kann vollkommen geräuschlos und stoßfrei gestaltet werden.

b) Die Fahrwiderstände verringern sich für hohe Fahrgeschwindigkeiten.

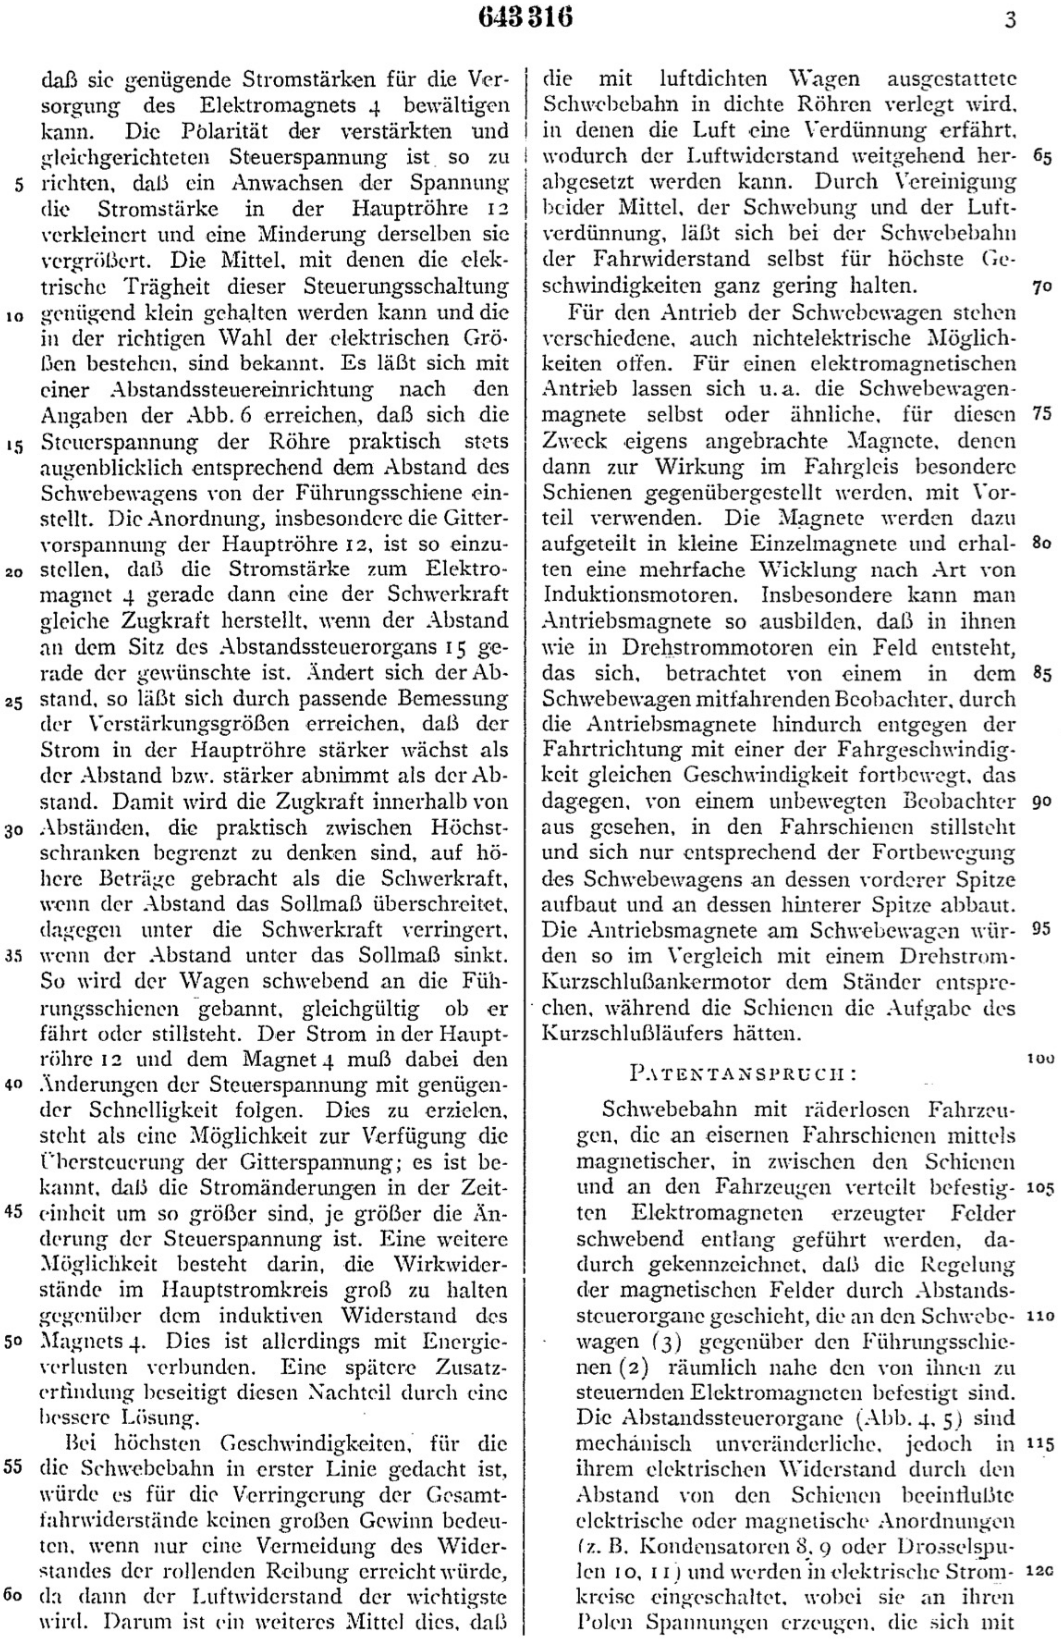
c) Die Abnutzung der Schienen durch das Befahren fällt fort.

d) Es sind Fahrgeschwindigkeiten erreichbar, die mehrfach so hoch sind als die, welche man bei den Eisenbahnen heute kennt.

Abb. 4 und 5 geben Beispiele für die Abstandssteuerorgane. Abb. 4 deutet ein Abstandssteuerorgan an, dessen Kapazität vom Abstand zwischen Schwebewagen 3 und Führungsschiene 2 abhängt. Es besteht aus zwei isoliert am Schwebewagen befestigten Platten 8, 9 mit Stromzuführungsleitungen. Ersichtlich schließt sich ein dielektrischer Verschiebungsstrom zwischen den Platten bei geeigneter Formgebung in der Hauptsache über das Metall der Schiene 2. Die Platten bilden also einen Kondensator, dessen Kapazität mit geringer werdendem Abstand zwischen Schwebewagen und Schiene wächst, umgekehrt sich mindert. In Abb. 5 ist das Abstandssteuerorgan ein kleinerer, am Schwebewagen 3 befestigter Elektromagnet, bei dem sich die seinen Kern 10 durchsetzenden Kraftlinien in erster Linie über das Eisen der Schiene 2 schließen. Wird solch ein Elektromagnet mit seiner Wicklung 11 in einen Stromkreis geschaltet, so stellt er offenbar darin eine Induktivität dar, deren Größe mit Annäherung des Schwebewagens an die Führungsschiene wächst, mit Entfernung sich jedoch mindert.

Abb. 6 zeigt nun den grundsätzlichen Schaltungsaufbau für die Regelung der Stromstärke in einem der Elektromagnete, beispielsweise 4. Es ist als Abstandssteuerorgan 15 an einen Kondensator nach Abb. 4 gedacht. Dieser Kondensator ist mit einem Widerstand 14 in Reihe an eine konstante Wechselspannung 16 hoher Frequenz gelegt. Der Spannungsabfall am Widerstand 14 steigt nun mit Annäherung des Schwebewagens an die Schiene und fällt mit sich vergrößernder Entfernung. Die Spannung an dem Widerstand 14 wird durch eine mit bekannten Mitteln der Elektronentechnik aufzubauende Verstärker- und Gleichrichteranordnung 13 verstärkt und gleichgerichtet und dann zur Gittersteuerung einer Hauptröhre 12 verwendet, die so bemessen ist,

Figure C.128: German patent DE643316 on magnetically levitated trains, filed by Hermann Kemper in 1934.



daß sie genügende Stromstärken für die Versorgung des Elektromagnets 4 bewältigen kann. Die Polarität der verstärkten und gleichgerichteten Steuerspannung ist so zu richten, daß ein Anwachsen der Spannung die Stromstärke in der Hauptröhre 12 verkleinert und eine Minderung derselben sie vergrößert. Die Mittel, mit denen die elektrische Trägheit dieser Steuerungsschaltung genügend klein gehalten werden kann und die in der richtigen Wahl der elektrischen Größen bestehen, sind bekannt. Es läßt sich mit einer Abstandssteuereinrichtung nach den Angaben der Abb. 6 erreichen, daß sich die Steuerspannung der Röhre praktisch stets augenblicklich entsprechend dem Abstand des Schwebewagens von der Führungsschiene einstellt. Die Anordnung, insbesondere die Gittervorspannung der Hauptröhre 12, ist so einzustellen, daß die Stromstärke zum Elektromagnet 4 gerade dann eine der Schwerkraft gleiche Zugkraft herstellt, wenn der Abstand an dem Sitz des Abstandssteuerorgans 15 gerade der gewünschte ist. Ändert sich der Abstand, so läßt sich durch passende Bemessung der Verstärkungsgrößen erreichen, daß der Strom in der Hauptröhre stärker wächst als der Abstand bzw. stärker abnimmt als der Abstand. Damit wird die Zugkraft innerhalb von Abständen, die praktisch zwischen Höchstschranken begrenzt zu denken sind, auf höhere Beträge gebracht als die Schwerkraft, wenn der Abstand das Sollmaß überschreitet, dagegen unter die Schwerkraft verringert, wenn der Abstand unter das Sollmaß sinkt. So wird der Wagen schwebend an die Führungsschienen gebannt, gleichgültig ob er fährt oder stillsteht. Der Strom in der Hauptröhre 12 und dem Magnet 4 muß dabei den Änderungen der Steuerspannung mit genügender Schnelligkeit folgen. Dies zu erzielen, steht als eine Möglichkeit zur Verfügung die Übersteuerung der Gitterspannung; es ist bekannt, daß die Stromänderungen in der Zeiteinheit um so größer sind, je größer die Änderung der Steuerspannung ist. Eine weitere Möglichkeit besteht darin, die Wirkwiderstände im Hauptstromkreis groß zu halten gegenüber dem induktiven Widerstand des Magnets 4. Dies ist allerdings mit Energieverlusten verbunden. Eine spätere Zusatzerfindung beseitigt diesen Nachteil durch eine bessere Lösung.

Bei höchsten Geschwindigkeiten, für die die Schwebebahn in erster Linie gedacht ist, würde es für die Verringerung der Gesamtfahrwiderstände keinen großen Gewinn bedeuten, wenn nur eine Vermeidung des Widerstandes der rollenden Reibung erreicht würde, da dann der Luftwiderstand der wichtigste wird. Darum ist ein weiteres Mittel dies, daß die mit luftdichten Wagen ausgestattete Schwebebahn in dichte Röhren verlegt wird, in denen die Luft eine Verdünnung erfährt, wodurch der Luftwiderstand weitgehend herabgesetzt werden kann. Durch Vereinigung beider Mittel, der Schwebung und der Luftverdünnung, läßt sich bei der Schwebebahn der Fahrwiderstand selbst für höchste Geschwindigkeiten ganz gering halten.

Für den Antrieb der Schwebewagen stehen verschiedene, auch nichtelektrische Möglichkeiten offen. Für einen elektromagnetischen Antrieb lassen sich u. a. die Schwebewagenmagnete selbst oder ähnliche, für diesen Zweck eigens angebrachte Magnete, denen dann zur Wirkung im Fahrgleis besondere Schienen gegenübergestellt werden, mit Vorteil verwenden. Die Magnete werden dazu aufgeteilt in kleine Einzelmagnete und erhalten eine mehrfache Wicklung nach Art von Induktionsmotoren. Insbesondere kann man Antriebsmagnete so ausbilden, daß in ihnen wie in Drehstrommotoren ein Feld entsteht, das sich, betrachtet von einem in dem Schwebewagen mitfahrenden Beobachter, durch die Antriebsmagnete hindurch entgegen der Fahrtrichtung mit einer der Fahrgeschwindigkeit gleichen Geschwindigkeit fortbewegt, das dagegen, von einem unbewegten Beobachter aus gesehen, in den Fahrschienen stillsteht und sich nur entsprechend der Fortbewegung des Schwebewagens an dessen vorderer Spitze aufbaut und an dessen hinterer Spitze abbaut. Die Antriebsmagnete am Schwebewagen würden so im Vergleich mit einem Drehstrom-Kurzschlußankermotor dem Ständer entsprechen, während die Schienen die Aufgabe des Kurzschlußläufers hätten.

PATENTANSPRUCH:

Schwebebahn mit räderlosen Fahrzeugen, die an eisernen Fahrschienen mittels magnetischer, in zwischen den Schienen und an den Fahrzeugen verteilt befestigten Elektromagneten erzeugter Felder schwebend entlang geführt werden, dadurch gekennzeichnet, daß die Regelung der magnetischen Felder durch Abstandssteuerorgane geschieht, die an den Schwebewagen (3) gegenüber den Führungsschienen (2) räumlich nahe den von ihnen zu steuernden Elektromagneten befestigt sind. Die Abstandssteuerorgane (Abb. 4, 5) sind mechanisch unveränderliche, jedoch in ihrem elektrischen Widerstand durch den Abstand von den Schienen beeinflußte elektrische oder magnetische Anordnungen (z. B. Kondensatoren 8, 9 oder Drosselspulen 10, 11) und werden in elektrische Stromkreise eingeschaltet, wobei sie an ihren Polen Spannungen erzeugen, die sich mit

Figure C.131: German patent DE643316 on magnetically levitated trains, filed by Hermann Kemper in 1934.

[Multiple groups of German-speaking scientists developed and demonstrated electromagnetic railguns. The best-documented group was led by Joachim Hänsler (German, 19??–19??), but there were other groups as well. Manfred von Ardenne led a large program that was actually mass-producing railguns for battlefield use. The following documents describe some of the wartime work on railguns.]

CIOS XXXI-59. *Gesellschaft für Geratebau.* pp. 3–4.

The above-named target, which was formerly post of the Heereswaffenamt in Berlin, is an experimental station for the study of electrical means for accelerating projectiles. Although it has not yet produced practical results (only laboratory tests have so far been made), the project merits the attention of Army Ordnance.

Attempts to replace powder by electricity are not new. Many schemes were tried by this laboratory, and the method developed during the last war by Fauchon-Villiplee was finally adopted. The great difficulty is, of course, the developing of enough power to launch a projectile. It has been possible here to accelerate a body weighing 12 g to 1100 m/sec. in a 2-meter tube, which corresponds to an acceleration of about 30,000 times gravity. Coupling two such tubes was not very successful, 1200 m/sec. being obtained.

The projectile is accelerated by a "linear motor", which consists in its simplest form of two conductors (parallel rails) across which the projectile completes the circuit by means of fins attached to its rear. When current passes through the circuit, the projectile travels forward. The conventional electromagnetic equations apply to the process.

The principle was demonstrated to me in a 50 cm. tube with the projectiles submitted with this report. After firing, the edges of the copper fins are melted. The muzzle velocity in the demonstration was low.

The difficulties in the way of a suitable power source are formidable. Lead-sulfuric acid storage batteries with very thin plates are used for experimental work; 9000 kW is available from this source. Condensers to give 2000 volts with 24,000 microfarads capacity are also installed.

The great advantages of the electrical scheme would be (1) gun barrel unnecessary (2) higher velocity than is attainable with powder (3) higher efficiency than with powder (4) lower energy cost than with powder.

Work was about to begin on a projectile 1 cm. in diameter, weighing 60 or 70 grams. An A.A. gun was planned (see the attached report), which would have required a maximum current of 1,500,000 amperes at 1300 volts to launch a 4 cm. projectile. The power was to be obtained from three unipolar generators weighing 150 tons each.

Projectiles electrically launched would have to be fin-stabilized since they could not be rotated. Fin-stabilization presupposes wind-tunnel work, which explains the close cooperation between this target and the Peenemünde wind tunnel personnel at Kochel.

[The remaining pages of CIOS XXXI-59 include an English translation of a few pages of Joachim Hänsler's theoretical calculations.]

CIOS XXXI-84. ***German and Danish Industries.*** **pp. 103–105**

REPORT ON VISIT TO GESELLSCHAFT FÜR GERÄTEBAU m.b.H.
AT KLAIS NEAR MITTENWALD

The above firm moved from Berlin in April 1944, and succeeded in establishing itself, with all of its equipment, in a house near Mittenwald. The entire staff (of 30 people) was brought from Berlin.

The object of the undertaking was the development of a high velocity electro-magnetic gun. Dr. Hänsler, head of the firm, was interviewed. It is understood that Wing Commander Day, RAF, team leader of CIOS trip No. 415, had visited the firm on the 13th June, 1945, and took copies of two reports, giving an account of theory of operation of the gun, and of experiments carried out between the 4th September 1944, and the 31st May 1945. We also took copies of these reports.

Dr. Hänsler began by giving reasons why the development of a high velocity electro-magnetic gun was desirable. Theoretical calculations, supported by practical evidence, had led to the surprising conclusion that the charge of hitting with a heavy A.A. gun (e.g. 88 mm) was greater with a direct action fuse than with a time fuse. If a direct action fuse is used, a small projectile, containing a charge of only 500 gm, is sufficient to destroy an aircraft, whereas with a time fuse, as large a shell as possible is required. If, therefore, a means of firing a small shell with a high muzzle velocity (m-v) could be developed, a large economy could be effected. The rate of fire would also be greater than with a heavy gun.

A second reason given by Dr. Hänsler for requiring a high m-v, was that to engage a high speed aircraft flying at 12 or 15 km, it is necessary to open fire at a range of 20 or 30 km at least, and a high m-v is necessary to reach this range.

There is a theoretical upper limit, of 2,800 m/sec to the velocity attainable, using explosive propellant, and the maximum ever achieved in practise is 1600 m/s. An m-v of 2,000 m/sec or more is required. Dr. Hänsler had in mind a shell of diameter 4 cm and length 80 cm, unrotated and stabilised by fins.

Various types of electro-magnetic guns have been described in the literature. At first, Dr. Hänsler made some experiments with a solenoid gun, but soon dropped this system for the one described below. We were shown photographs of solenoids which had burst in operation.

The method of propulsion finally adopted was to have two parallel copper conductors, running the length of the gun, to which a potential was applied. A sliding copper bridge was propelled along these conductors under the action of the electro-mechanical forces resulting from the very heavy currents which flowed.

In the model guns made up at the present time there was also a “field winding” consisting of a single turn of heavy copper running the length of the gun, in the same plane as the conductors. This can be connected either in series or in parallel with the conductors. Use is made of iron to concentrate the magnetic field. In the next experimental gun, which is designed, but not built, the field winding will be omitted, and no magnetic material will be used, except for an outer sheath.

We were shown an experimental gun 2 m long which was capable of firing a 10 gm projectile with a velocity of 1200 m/s. This was not in operation, but if permission were given, could be made to work in two weeks time. We were given a demonstration with a model gun 50 cm long, working off two 12 v car batteries. This was said to given an m-v of 60 m/s.

Power for the experimental 2 m gun was obtained from a battery of 1,000 12 v accumulators of standard lead-acid type, each capable of giving 9 kw for a short time.

Development work was going on at Friemann and Wolf at Zwickau with a view to producing a special type of accumulator capable of giving a high current for a short time, the principle being to increase the surface area of the plates as much as possible. The firm were making 50 of a type that would give 20,000 to 40,000 amps for one tenth to one hundredth part of a second: the size of this accumulator, which was of the lead acid type, was to be 20 x 17 x 40 cm. These were not however, delivered when the war ended.

The use of condensers as a source of power had also been considered and a battery of condensers (24,000 mfd, 200 v) was installed in the laboratory. Little work had been done on this method, but Herr Muck of Staffelsee near Murnau, was said to have ideas on the subject. It was stressed that the power supplies used up to the present were suitable for laboratory experiments only. Work had just been started on a rotating machine which, it was hoped, would be capable of development into a practical device.

Briefly, this consisted of two rotating copper rings, like slip rings, but cut and insulated at one place. These rings were joined together on one side of the cut. Each ring had a copper brush bearing on it, from which the power output was taken. If, when the rings were rotating, a pulse of current from a condenser were applied at the correct time, a magnetic field would be built up rapidly and the machine would deliver power for one rotation. This machine had not yet been completed.

The 2 m gun referred to above, behaved in accordance with theory, as regards relation between field and conductor currents and m-v. When an attempt to put two together and make a 4 m gun was made, however, the expected increase in m-v was not obtained.

The next gun projected was to fire a 6.5 kg projectile, which would be so designed that the propelling bridge would drop off as soon as it left the gun.

In addition to work on the gun itself, a number of associated investigations were being carried out: they were

(1) Development of a conductor with a low self inductance for connecting the gun to the power supply. This was obtained by mounting the two conductors very close together with a layer of insulating material between.

(2) Development of a method of measuring self inductances less than 10^{-5} henries. The method was to form a tuned circuit including the self inductance, shock excite it, and record the resulting damped wave on an oscillograph.

(3) Development of an iron inductance shunt for measuring heavy currents. The principle was as in one (1)

The laboratory was well equipped for measuring m-v. The method was to fire the projectile through wire screens, and record the resulting electrical impulses on a moving film using a high speed loop oscilloscope. Current waveforms in the gun could be recorded at the same time. We were shown an electrical counter device which would give a direct reading of transit time in milli-secs. This had not been designed by the firm but had been purchased. It was about to be put into use in conjunction with a pair of photo-electric devices for recording the passage of the projectile.

These were two slow motion cameras for photographing the projectile in flight. A high speed oscilloscope using a Cathode Ray tube was being developed.

On the whole we formed the impression that the work being carried out by this firm was very far from having any military application.

Joachim Hänsler. 1945 reports. [NARA RG 319, Entry NM-82A, Box 15, Folders OB-27 and OB-28]

[The copies of Hänsler's reports that were obtained and filed by the U.S. Alsos Mission are quite lengthy and extremely detailed, covering his designs, theoretical calculations, experimental measurements, and photographs of the projectiles that he tested. Please see photos of selected pages from these reports on the following pages.

As documented in these reports and the preceding CIOS reports, Hänsler built and demonstrated electromagnetic railguns capable of launching projectiles at velocities up to 1200 meters/second, or over 3.5 times the speed of sound. As of the time of these reports, he was continuing to develop larger and faster railguns, planning to reach velocities over 2000 meters/second.]

- 6 -

$$i = e^{-\varrho t}\cdot\left(\mathfrak{J}_1\cos\omega t + \mathfrak{J}_2\sin\omega t\right) \qquad (10)$$

Die Bestimmung der Konstanten geschieht wie folgt:

Ist für $t = 0$: $i = \mathfrak{J}'$ und $v = v'$, so folgt aus (10)

$$\mathfrak{J}_1 = \mathfrak{J}' \qquad (11)$$

und damit $i = e^{-\varrho t}\cdot\left(\mathfrak{J}'\cos\omega t + \mathfrak{J}_2\sin\omega t\right)$ (12)

und durch Differentation (13)

$$\frac{di}{dt} = -\varrho\cdot e^{-\varrho t}\left(\mathfrak{J}'\cos\omega t + \mathfrak{J}_2\sin\omega t\right) + \omega\cdot e^{-\varrho t}\left(-\mathfrak{J}'\sin\omega t + \mathfrak{J}_2\cos\omega t\right)$$

Aus (4) folgt $\dfrac{di}{dt} = \dfrac{U_0 - R\cdot\mathfrak{J}' - \mathfrak{B}\cdot\ell\cdot v'}{\mathfrak{L}}$ (14)

Durch Gleichsetzen der beiden Werte für $\dfrac{di}{dt}$ folgt

$$\mathfrak{J}_2 = \frac{U_0 - R\cdot\mathfrak{J}' - \mathfrak{B}\cdot\ell\cdot v'}{\omega\mathfrak{L}} + \frac{\varrho}{\omega}\cdot\mathfrak{J}' \qquad (15)$$

Schließlich ist (16)

$$i = e^{-\varrho t}\cdot\left[\mathfrak{J}'\cos\omega t + \left(\frac{U_0 - R\cdot\mathfrak{J}' - \mathfrak{B}\cdot\ell\cdot v'}{\omega\mathfrak{L}} + \frac{\varrho}{\omega}\cdot\mathfrak{J}'\right)\sin\omega t\right]$$

Diese Gleichung wird zur schritt- und näherungsweisen Lösung der Differentialgleichung bei variablen $\mathfrak{L}$, R und $\mathfrak{B}$ benötigt. Sind $\mathfrak{L}$, R und $\mathfrak{B}$ konstant und benutzt man als Anfangsbedingung

$$\mathfrak{J}' = 0 \text{ und } v' = 0 \qquad (17)$$

so folgt $i = \dfrac{U_0}{\omega\mathfrak{L}}\cdot e^{-\varrho t}\cdot\sin\omega t$ (18)

Aus (18) lässt sich durch Differentation und Nullsetzung der max. Strom in Amp. berechnen, für den die Stromquelle bemessen werden muss, sowie die Zeit t', nach welcher der max. Strom erreicht wird:

$$\frac{di}{dt} = \frac{U_0}{\omega\mathfrak{L}}\cdot e^{-\varrho t'}\left(\omega\cos\omega t' - \varrho\sin\omega t'\right) = 0 \qquad (19)$$

$$\omega\cos\omega t' - \varrho\sin\omega t' = 0 \qquad (20)$$

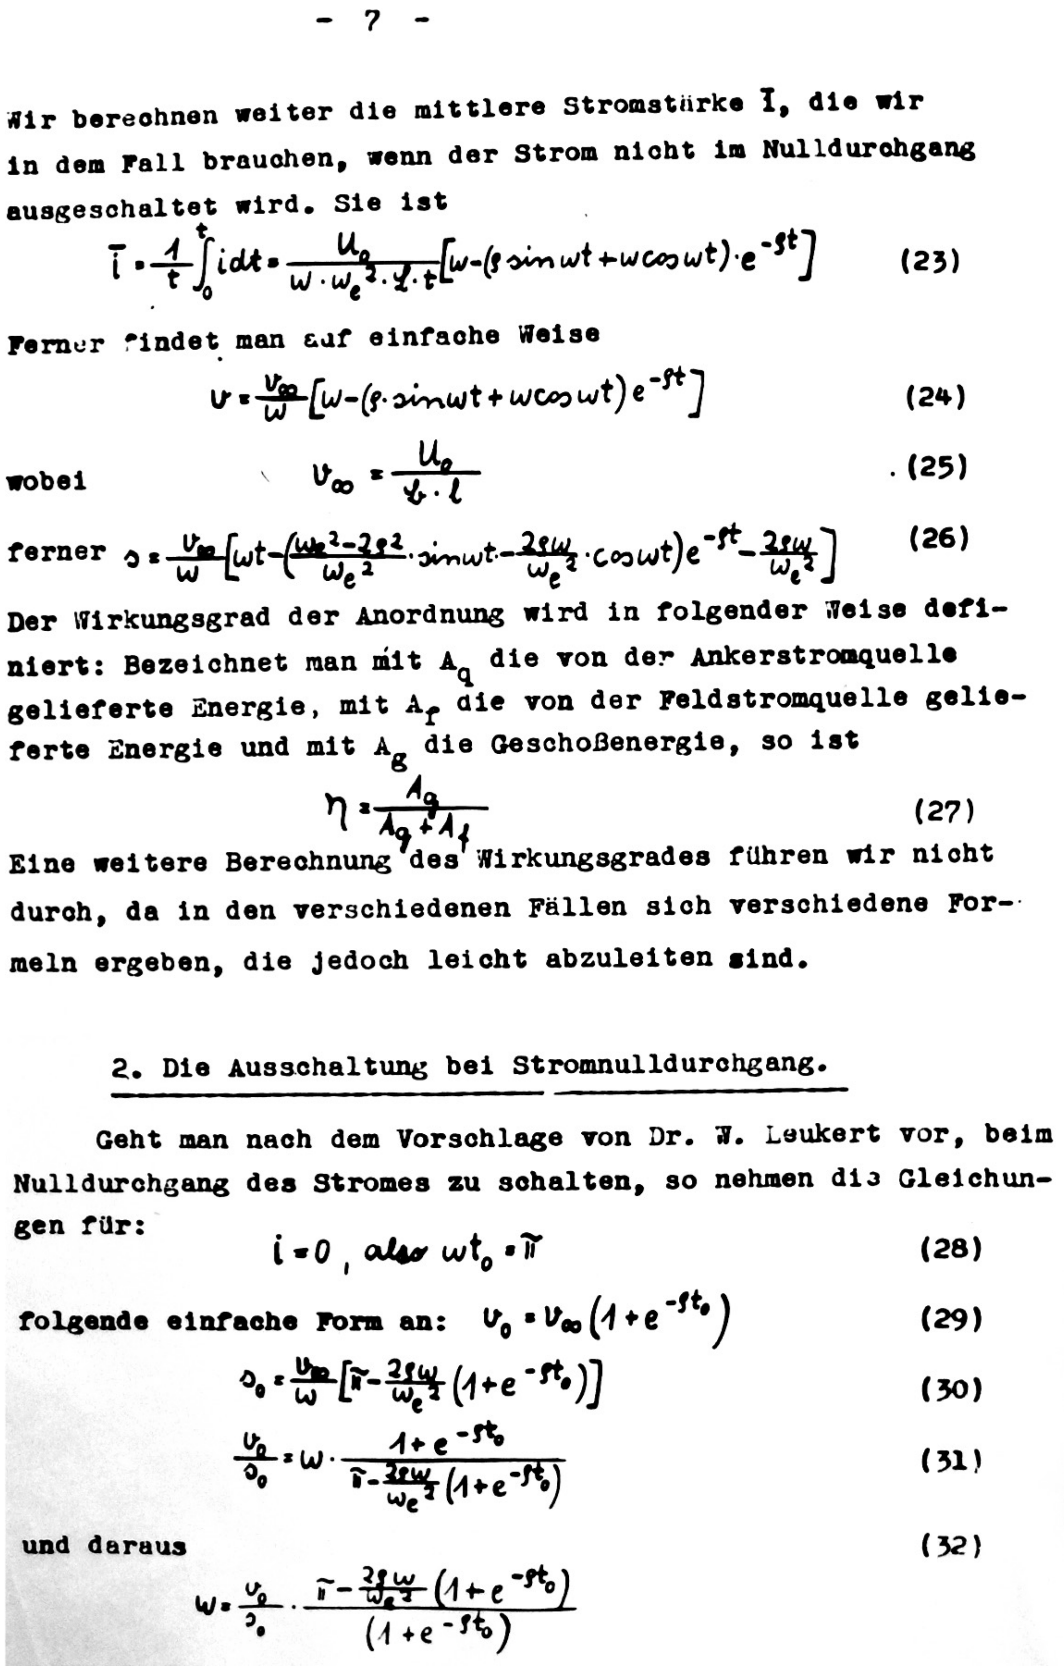
$$\mathrm{tg}\,\omega t' = \frac{\omega}{\varrho} \qquad (21)$$

Damit wird (22)

$$i_{max} = \frac{U_0}{\omega\mathfrak{L}}\cdot e^{-\varrho t'}\cdot\sin\omega t'$$

Figure C.134: Part of Joachim Hänsler's 1945 reports on the development and testing of electromagnetic railguns.

DECLASSIFIED
Authority NND 755001



- 7 -

Wir berechnen weiter die mittlere Stromstärke $\bar{I}$, die wir in dem Fall brauchen, wenn der Strom nicht im Nulldurchgang ausgeschaltet wird. Sie ist

$$\bar{i} = \frac{1}{t}\int_0^t i\,dt = \frac{U_e}{\omega\cdot\omega_e^2\cdot\mathcal{L}\cdot t}\left[\omega-(\rho\sin\omega t+\omega\cos\omega t)\cdot e^{-\rho t}\right] \qquad (23)$$

Ferner findet man auf einfache Weise

$$v = \frac{v_\infty}{\omega}\left[\omega-(\rho\cdot\sin\omega t+\omega\cos\omega t)e^{-\rho t}\right] \qquad (24)$$

wobei

$$v_\infty = \frac{U_e}{\mathcal{L}\cdot l} \qquad .(25)$$

ferner $s = \frac{v_\infty}{\omega}\left[\omega t-\left(\frac{\omega_e^2-2\rho^2}{\omega_e^2}\cdot\sin\omega t-\frac{2\rho\omega}{\omega_e^2}\cdot\cos\omega t\right)e^{-\rho t}-\frac{2\rho\omega}{\omega_e^2}\right]$ (26)

Der Wirkungsgrad der Anordnung wird in folgender Weise definiert: Bezeichnet man mit A_q die von der Ankerstromquelle gelieferte Energie, mit A_f die von der Feldstromquelle gelieferte Energie und mit A_g die Geschoßenergie, so ist

$$\eta = \frac{A_g}{A_q+A_f} \qquad (27)$$

Eine weitere Berechnung des Wirkungsgrades führen wir nicht durch, da in den verschiedenen Fällen sich verschiedene Formeln ergeben, die jedoch leicht abzuleiten sind.

2. Die Ausschaltung bei Stromnulldurchgang.

Geht man nach dem Vorschlage von Dr. W. Leukert vor, beim Nulldurchgang des Stromes zu schalten, so nehmen die Gleichungen für:

$$i = 0\,,\ \text{also}\ \omega t_0 = \pi \qquad (28)$$

folgende einfache Form an: $v_0 = v_\infty\left(1+e^{-\rho t_0}\right)$ (29)

$$s_0 = \frac{v_\infty}{\omega}\left[\pi-\frac{2\rho\omega}{\omega_e^2}\left(1+e^{-\rho t_0}\right)\right] \qquad (30)$$

$$\frac{v_0}{s_0} = \omega\cdot\frac{1+e^{-\rho t_0}}{\pi-\frac{2\rho\omega}{\omega_e^2}\left(1+e^{-\rho t_0}\right)} \qquad (31)$$

und daraus (32)

$$\omega = \frac{v_0}{s_0}\cdot\frac{\pi-\frac{2\rho\omega}{\omega_e^2}\left(1+e^{-\rho t_0}\right)}{\left(1+e^{-\rho t_0}\right)}$$

Anlage

zum Entwurf

für eine Elektrische 4 cm Flak.

Der vorliegende Entwurf ist seinerzeit lediglich als Diskussionsgrundlage zusammengestellt worden. Er ist kurz, weil vieles als bekannt vorausgesetzt werden konnte. Insbesondere fehlen alle experimentellen Ergebnisse.

In zweifacher Hinsicht bedarf der Entwurf aber einer Korrektur

1) Die Seite 10 näherungsweise abgeleitete Kraftformel (43) differiert zu stark mit der exakt durch Integration gewonnenen. Es ist (siehe Bild)

$$P = \frac{\mu_0}{2\pi} i^2 \ln \frac{2a-b}{b} \left[\frac{Wsec}{cm}\right]$$

und mit $\mu_0 = 1{,}256 \cdot 10^{-8}$ wird

$$P = 2 \cdot 10^{-8} i^2 \ln \frac{2a-b}{b} \quad [kp]$$

Vor allem fehlt in (43) die - wenn auch schwache - Abhängigkeit von den geometrischen Dimensionen.

2) Wir forderten, dass die Induktion der Unipolarmaschine von 20 000 auf 40 000 Gauss heraufgesetzt werde (Seite 15 f). Eine Prüfung ergab, dass diese Änderung nicht durchführbar ist. Auch nach dieser Änderung wäre diese Maschine nur ein Behelf gewesen. Man hätte drei Maschinen in Serie schalten müssen, um die erforderliche Spannung aufzubringen. Die Selbstinduktion aber könnte man niemals auf den gewünschten kleinen Wert reduzieren.

Es musste daher auch hier ein völlig neuer Weg gesucht werden. Wir glauben ihn in der Umkehrung des Linearmotorprinzips

ALSOS MIS

Versuchsbericht Nr. 1

Schiessperiode vom 4.9. bis 13.9.44

Am 4.9.44 waren die Vorbereitungen soweit gediehen, dass wieder mit Schiessversuchen begonnen werden konnte.

Aufgabe der ersten Schiessversuche ist, mit einem LM 2 die nach der Rechnung mit 2 m Rohrlänge größtmögliche V_0, d.h. etwa 1500 m/sec, zu erreichen und damit die maximale Stromdichte festzustellen. Die weitere Steigerung der Anfangsgeschwindigkeit wird dann in bekannter Weise durch Ansetzen weiterer Linearmotore gemacht werden,.

Bei den letzten Versuchen in Berlin wurde ausschließlich mit Lichtbogenkontakt als Stromzuführung zum Treibflügel gearbeitet. Mit Hilfe dieses Kontaktes war bei 4 m langer Rohr – zwei LM 2 – die größtmögliche V_0 800 m/sec. Die maximale Stromdichte betrug dabei etwa 600 A/mm^2. Rechnerisch war gezeigt worden, dass man mit Berührungskontakt zu ganz erheblich grösseren Stromdichten und damit auch Geschwindigkeiten vordringen kann.

Die jetzigen Versuche haben diese Überlegenheit des Berührungskontaktes erwiesen. Es wurden insgesamt 76 Schuss geschossen. Die Feldstromstärke betrug bei allen Schüssen 9500 bis 10 000 Amp., was einer effektiven Feldstärke von 43 000 Gauss im Luftspalt entspricht. Die mittlere Ankerstromstärke wurde von 2400 Amp. auf 7400 Amp. gesteigert. Die Geschwindigkeit stieg dabei von 310 auf 630 m/sec (Bild 1). Die Kontaktstücke wurden bei den verwendeten Ankerstromstärken bis 7400 Amp. mittlerer Stromstärke (Spitze 8900 Amp.) nur ausserordentlich wenig angegriffen. (Siehe Bild 2). Der Kontaktdruck betrug etwa 5 kg. Das Oszillogramm des Stromverlaufes zeigt den absolut einwandfreien Kontakt (siehe Bild 3). Dabei ist die bisher verwendete grösste Stromdichte 1300 A/mm^2, also über doppelt so gross wie früher die maximale Stromdichte bei Lichtbogenkontakt.

Dadurch, dass sich die Gleitkontakte bei allen Schüssen absolut einwandfrei verhielten, konnte ein weiterer Fehler der Anordnung klar erkannt und schrittweise beseitigt werden. Der Luftspalt des Linearmotors LM 2 war so eng wie möglich (2,5 mm).

7. Ausfertigung

Versuchsbericht Nr. 2

Betr.: Versuche mit dem elektrischen Geschütz.

A. Schießperiode vom 26.9. - 24.10.1944

Die Polschuhe des LM 2 Nr. 12 wurden - wie im Versuchsbericht Nr. 1 beschrieben - umgebaut. Bild 1 zeigt die neuen und alten Polschuhe im Schnitt. Der Luftspalt zwischen den Polschuhen ist von 2,5 auf 3,5 mm erweitert worden, um ein Schleifen des Treibflügels an der Polschuhkante zu unterbinden. Da bei diesem Polschuh die Geschossführung aus Messing, also aus unmagnetischem Material, besteht, können hiermit auch Geschosse aus Eisen verschossen werden. Bild 2 zeigt eine Zusammenstellung der mit Eisengeschossen erhaltenen Resultate.

Entgegen der Erwartungen konnte die Geschwindigkeit mit dem LM 2 Nr. 12 zunächst nicht gesteigert werden. Es lag im Gegenteil die Maximalgeschwindigkeit nicht wie bei den ersten Versuchen um 630 m/sec - siehe Versuchsbericht Nr. 1 -, sondern um 570 m/sec. Der Grund schien allein in dem Umbau des Geschützes liegen zu können,und es wurden die Versuche mit dem LM 2 Nr. 11 wiederholt. Die Geschwindigkeit lag ebenfalls um 60 m/sec zu tief. Um den Grund dafür zu finden, wurde mit drei verschiedenen Feldstärken (15 000, 43 000, 63 000 C.G.S.) gearbeitet. In Bild 3 sind die bei den verschiedenen Feldstärken maximal erreichten Geschwindigkeiten zusammengestellt. Sowohl bei 15 000 wie bei 63 000 C.G.S. bleiben die gemessenen hinter den errechneten Werten etwas zurück. In beiden Fällen werden die Treibflügel also bereits überbeansprucht. Bei 63 000 C.G.S. ist das Hinzukommen eines weiteren Grundes wahrscheinlich. Die Feldstärken in Abhängigkeit von der Stromstärke sind in bekannter Weise berechnet worden. Bild 4 zeigt diese Abhängigkeit für LM 2/11 und LM 2/12. Möglicherweise bleiben im Gebiet der Feldstärken > 50 000 C.G.S. die tatsächlich erreichten Feldstärken gegenüber den errechneten zurück. Es wird dies noch durch Messungen geprüft werden.

8 Ausfertigungen:
6. Ausfertigung

Versuchsbericht Nr. 3

Betr.: Versuche mit dem elektrischen Geschütz.

A. Versuche in der Zeit vom 7.11. bis 12.12.1944 mit dem LM 2/13.

Mit dem Linearmotor LM 2/13 (Rohrlänge 2 m) wurden die im Versuchsbericht Nr. 2 beschriebenen Versuche fortgesetzt mit dem Ziel, die bisher erreichte Geschwindigkeit von 930 m/sec. weiter zu steigern. Bei diesem LM ist, wie bereits berichtet wurde, die Federung in die Kontaktschienen verlegt. Der Treibflügel hat keine Federung. Es wurden verschiedene Geschoßausführungen mit Treibflügeln aus 1 mm starkem Kupferblech mit aufgelöteten Kontaktstücken aus Wolfram erprobt. Schwierigkeiten bereitete es, die richtige Ausführung der Kontakte zu finden und sie so aufzulöten, dass sie sich beim Schuß nicht lösen. Sich ablösende Kontakte stellen sich in den Kontaktschienen quer und beschädigen diese. Aus Blech gestanzte Kontakte sind nicht so haltbar wie von Rundmaterial abgestochene. Mit letzterem hergestellte Geschosse wurden etwa 130 aus einem LM verschossen, ohne dass die Kontaktschienen beschädigt oder nennenswert abgenutzt wurden.

Das Geschoß E 22 mit rechteckigem Kontakt (Bild Nr. 3 und 4) hat sich neben dem Geschoß mit rundem Kontakt von 8 mm ø (E 19, Bericht Nr. 2, Bild 8) gut bewährt. Bei mittleren Ankerstromstärken von 21 000 A (max. 27 500 A) wurden

SECRET WEAPONS

ELECTROMAGNETIC ROCKET

ELEKTROMAGNETISCHE RÜCKSTOSSRAKETE

(Reference Note No. 6.900/R.G. of 22 May 1944).

This rocket is under research by the Electric Research Society of Von Arden [Manfred von Ardenne].

The apparatus is in course of being perfected, its manufacture is being carried out on seven factories of Posen. Launching emplacements have been completed. The wave length used is 2 m 40.

ELECTROMAGNETIC ROCKET
ELEKTROMAGNETISCHE RÜCKSTOSSRAKETE

It concerns a rocket of a caliber of 603 mm, launched electromagnetically through a smooth barrel of a length of 8 meters, by the successive cutting off of the current through a coil around the barrel.

The rocket is propelled through regeneration. The closing is controlled by a cathode oscillator loading the condenser blades. The apparatus is under research by Von Ardenne.

The direction of the rocket is controlled by means of ailerons. The principal difficulty is the low speed of the rocket, estimated at 150 m/sec at the exit of the barrel, which makes it subject to atmospheric disturbances.

The construction controlled by the Navy is carried on in two groups:

1) Mechanical part: Barrel and rocket by MAGIRUS at Ula.
   Electrical part: by Siemens Schuckert at Nuremberg.
   This group has only been working for a few months.

2) Mechanical part: by Borsig at Borsigwald -Berlin-. Factory destroyed, manufacture transferred to Schwartzkoff, turbine constructor (in the suburb of Berlin) not yet ready. Electrical part: by Siemens & Halske at Siemensstadt, suburb north of Berlin. Factory destroyed—manufacture will be transferred to the annex of Posen. Moving has been set for the 22nd of April 1944.

Electrical control material: constructed by the research group Von Ardenne, is in course of being transferred to Posen.

Rocket ailerons are constructed by Karl Mahr at Esslingen (Würtemberg).

Precision material necessary for the equipment of the factories is collected in France for a total of 120 million francs at the official rate.

[In some of Igor Witkowski's books, he published an archival document that was an English translation of French intelligence reports from February 1944 [Witkowski 2010, pp. 129–131, and 2013, pp. 93–94]. See Figs. C.154–C.156. The document summarized several somewhat contradictory and garbled French intelligence reports, but they described French coastal emplacements for very large electromagnetic railguns with powers up to "10,000 kilowatts." The document may be related to the above French intelligence report. Witkowski did not give an archival source for the document in his books. Can the archive and archival location be identified?

Collectively these reports appear to demonstrate that during the war, electromagnetic railguns had moved beyond the stage of simple experiments. Very large railguns were being mass-produced in several factories, and sites were being built to house and power them on the battlefield.]

GERMANY ARMY
FRANCE
Various Information - Secret Weapon

Precisions on the characteristics of Guns and Shells.

3 Feb 44

We were able to show the outline of the "secret weapon" gun to an officer of the "Preparation of Terrain", who participated in the installation operations for these guns. He confirmed the exactitude of the outline, but as to the claiber of the rocket grenades, he thinks that they are 700 millimeters.

The grenade: man's height.

7 Feb 44

The rocket shell placed on a car crosses a tunnel about 3 kilometers long. (in concrete). The attraction is effected by an electromagnetic system. The power for the launching of the shell is that of 7,000 kilowatts, raised to 10,000 kilowats. The tunnel exist is inclined at a 50° angle.

Contrary to everything we have previously said, the container is propelled with the shell; the latter detaches itself only after it has been ejected.

Many accidents and breakdowns are caused by magnetic fields formed in the tunnel.

Diameter of the shell: 650 - wieght; 13 tons of which 8 tons are explosives.

(During the construction, the excavatinns were camouflaged and painted in green.)

9 Feb 44

We are concerned with a gun, firing shells which functions not by flashes or explosion, but by emission of acold wave - reaching 160°.

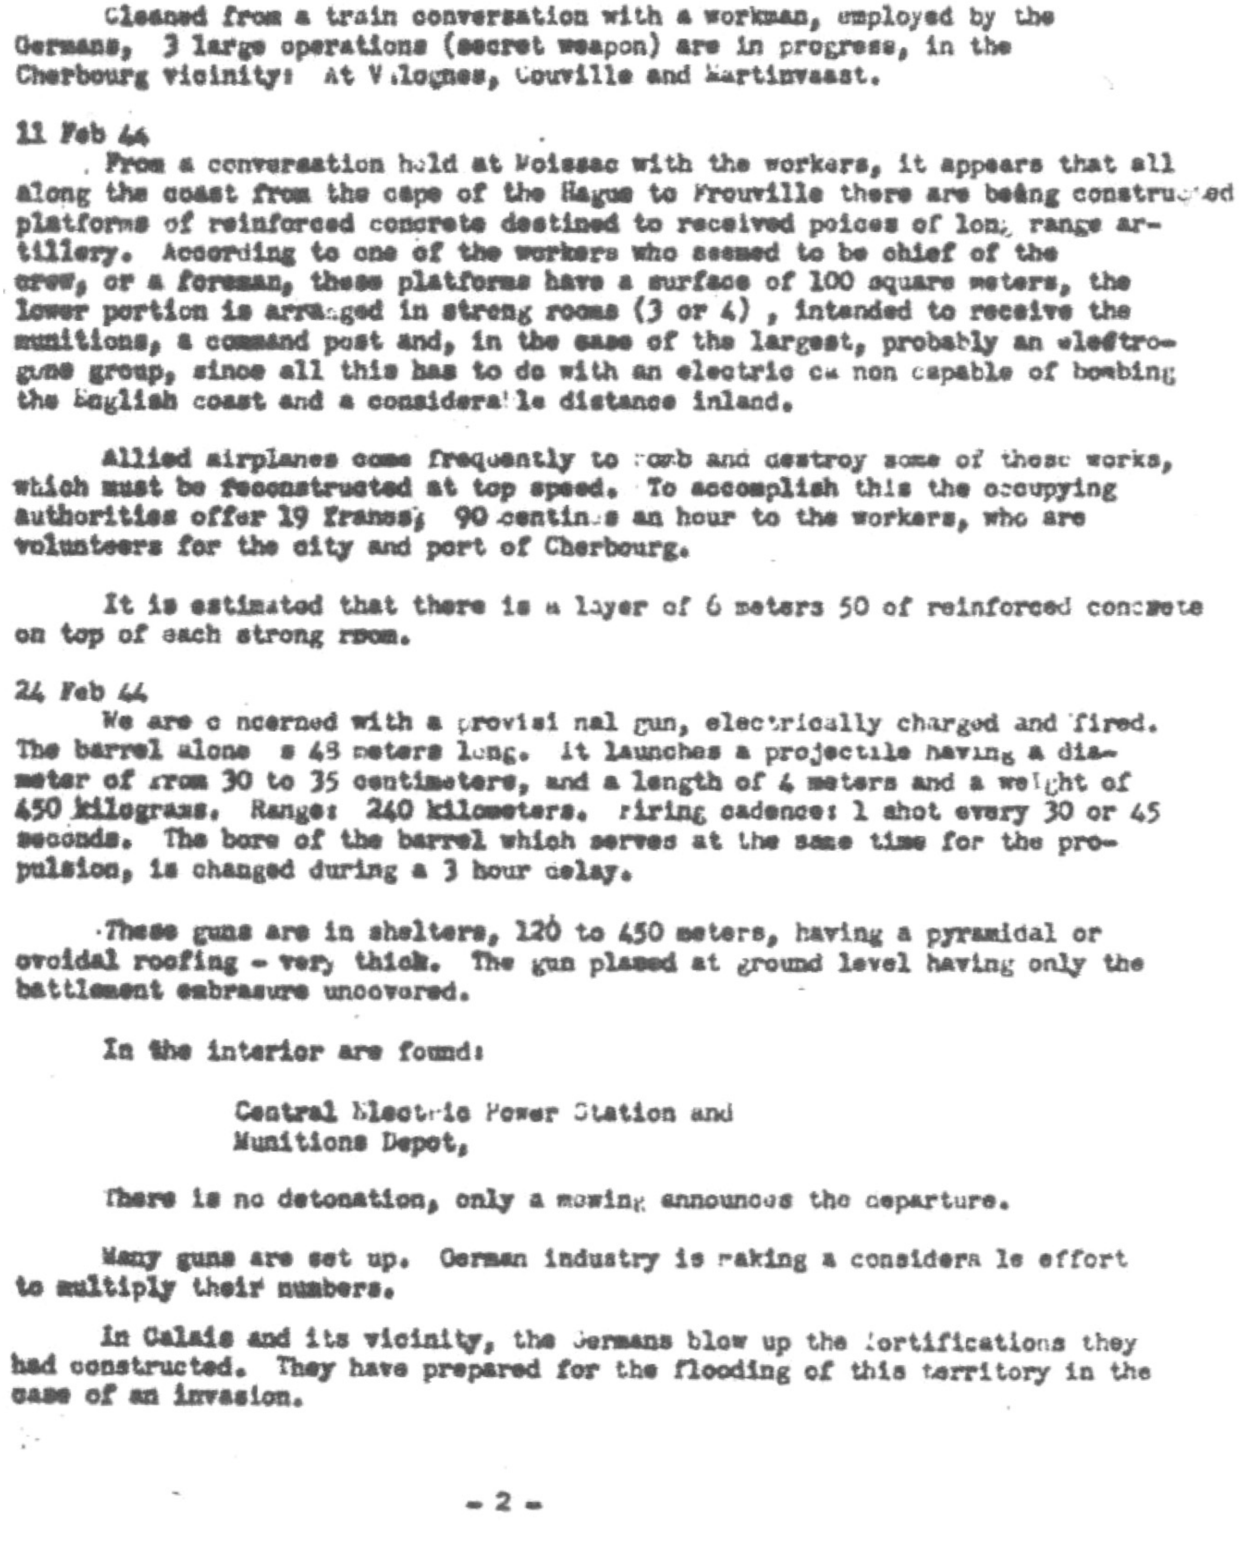
About 100 guns have already been set and numerous emplacements are being arranged.

(These guns will only be used in case of debarkatinn).

Intelligence on New Weapon Emplacements in the Hilly North Section.

CONFIDENTIAL

Figure C.154: English translation of French intelligence reports from February 1944 describing French coastal emplacements for very large electromagnetic railguns with powers up to "10,000 kilowatts" [Witkowski 2010, pp. 129–131, and 2013, pp. 93–94].



Gleaned from a train conversation with a workman, employed by the Germans, 3 large operations (secret weapon) are in progress, in the Cherbourg vicinity: At Valognes, Couville and Martinvaast.

11 Feb 44

From a conversation held at Moissac with the workers, it appears that all along the coast from the cape of the Hague to Frouville there are being constructed platforms of reinforced concrete destined to received pieces of long range artillery. According to one of the workers who seemed to be chief of the crew, or a foreman, these platforms have a surface of 100 square meters, the lower portion is arranged in strong rooms (3 or 4), intended to receive the munitions, a command post and, in the case of the largest, probably an electrogene group, since all this has to do with an electric canon capable of bombing the English coast and a considerable distance inland.

Allied airplanes come frequently to bomb and destroy some of these works, which must be reconstructed at top speed. To accomplish this the occupying authorities offer 19 francs, 90 centimes an hour to the workers, who are volunteers for the city and port of Cherbourg.

It is estimated that there is a layer of 6 meters 50 of reinforced concrete on top of each strong room.

24 Feb 44

We are concerned with a provisional gun, electrically charged and fired. The barrel alone is 48 meters long. It launches a projectile having a diameter of from 30 to 35 centimeters, and a length of 4 meters and a weight of 450 kilograms. Range: 240 kilometers. Firing cadence: 1 shot every 30 or 45 seconds. The bore of the barrel which serves at the same time for the propulsion, is changed during a 3 hour delay.

These guns are in shelters, 120 to 450 meters, having a pyramidal or ovoidal roofing - very thick. The gun placed at ground level having only the battlement embrasure uncovered.

In the interior are found:

Central Electric Power Station and
Munitions Depot,

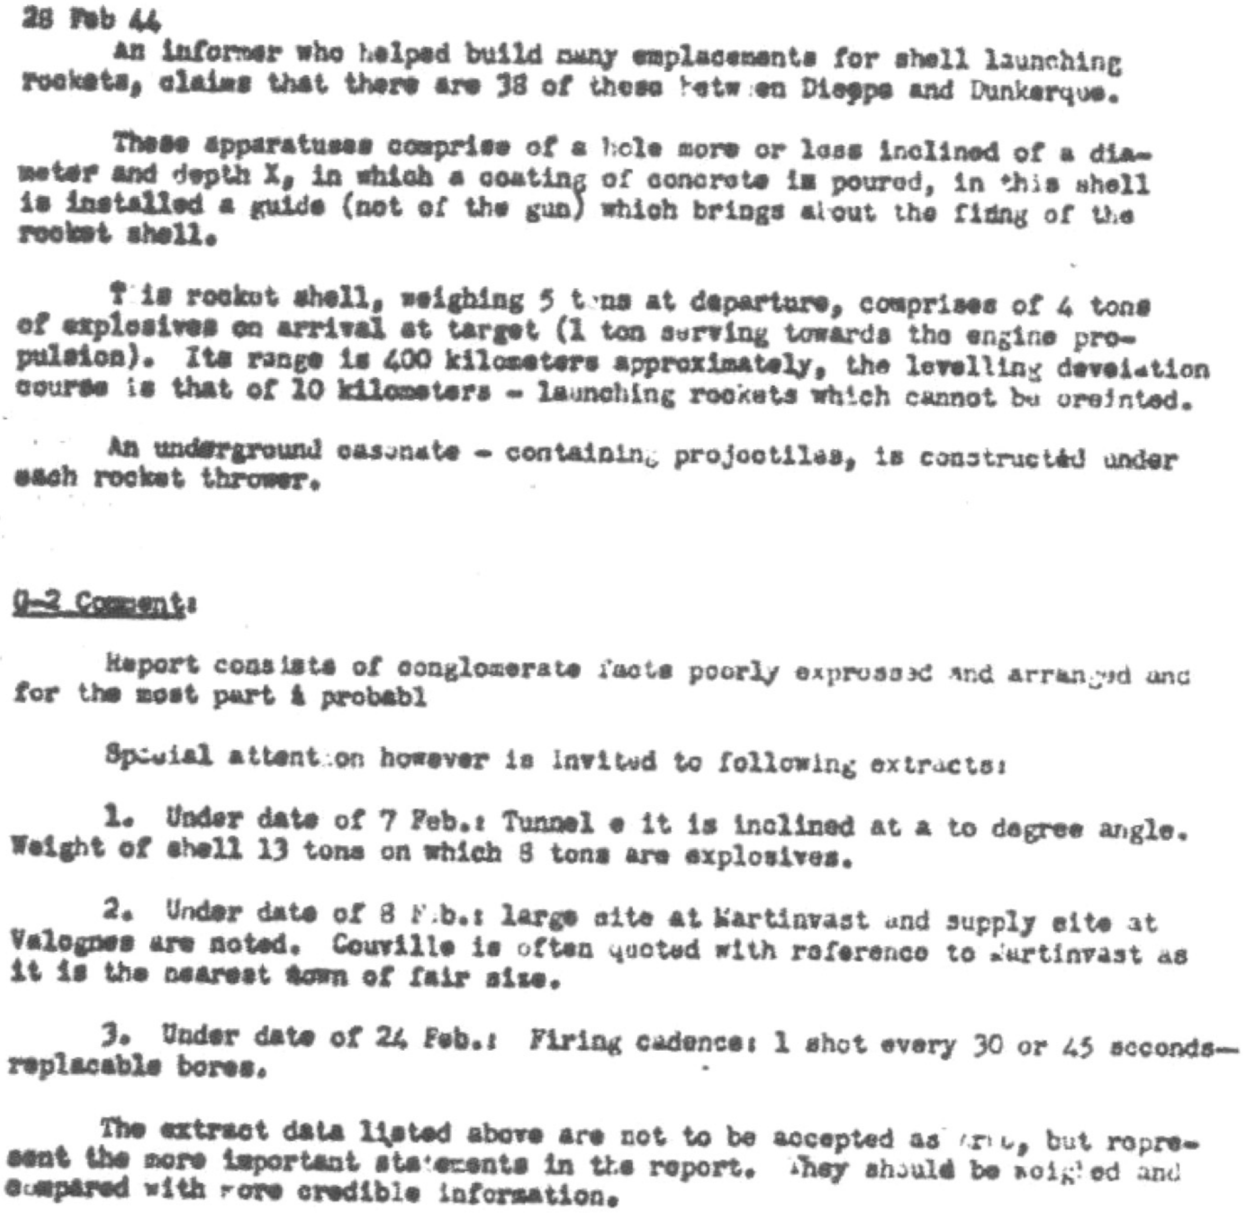
There is no detonation, only a mowing announces the departure.

Many guns are set up. German industry is making a considerable effort to multiply their numbers.

In Calais and its vicinity, the Germans blow up the fortifications they had constructed. They have prepared for the flooding of this territory in the case of an invasion.

- 2 -

Figure C.155: English translation of French intelligence reports from February 1944 describing French coastal emplacements for very large electromagnetic railguns with powers up to "10,000 kilowatts" [Witkowski 2010, pp. 129–131, and 2013, pp. 93–94].



28 Feb 44

An informer who helped build many emplacements for shell launching rockets, claims that there are 38 of these between Dieppe and Dunkerque.

These apparatuses comprise of a hole more or less inclined of a diameter and depth X, in which a coating of concrete is poured, in this shell is installed a guide (not of the gun) which brings about the firing of the rocket shell.

This rocket shell, weighing 5 tons at departure, comprises of 4 tons of explosives on arrival at target (1 ton serving towards the engine propulsion). Its range is 400 kilometers approximately, the levelling deveiation course is that of 10 kilometers - launching rockets which cannot be oreinted.

An underground casemate - containing projectiles, is constructed under each rocket thrower.

G-2 Comment:

Report consists of conglomerate facts poorly expressed and arranged and for the most part & probabl

Special attention however is invited to following extracts:

1. Under date of 7 Feb.: Tunnel e it is inclined at a to degree angle. Weight of shell 13 tons on which 8 tons are explosives.

2. Under date of 8 Feb.: large site at Martinvast and supply site at Valognes are noted. Couville is often quoted with reference to Martinvast as it is the nearest town of fair size.

3. Under date of 24 Feb.: Firing cadence: 1 shot every 30 or 45 seconds—replacable bores.

The extract data listed above are not to be accepted as true, but represent the more important statements in the report. They should be weighed and compared with more credible information.

Figure C.156: English translation of French intelligence reports from February 1944 describing French coastal emplacements for very large electromagnetic railguns with powers up to "10,000 kilowatts" [Witkowski 2010, pp. 129–131, and 2013, pp. 93–94].

Brendan Borrell. Electromagnetic Railgun Blasts Off. *Technology Review.* 6 February 2008. [https://www.technologyreview.com/2008/02/06/128211/electromagnetic-railgun-blasts-off/]

A supersonic bullet is fired with a record-breaking 10 megajoules of muzzle energy.

Last week at the Naval Surface Warfare Center, in Dahlgren, VA, a seven-pound bullet emerged from a truck-sized contraption at seven times the speed of sound and sent a visible shockwave through the air before crashing into a metal bunker filled with sand. With 10.6 megajoules of kinetic energy, this aluminum slug was propelled not by explosives but by an electric field, making this the most powerful electromagnetic railgun ever fired. The device is part of the navy's railgun development program.

While propellant-driven shells have been mainstays of naval warships for the past hundred years, the cost and safety issues related to storing explosive materials have driven engineers to seek alternatives like the electromagnetic railgun. "There are physical limits to what you can do with gunpowder," says Charles Garnett, the manager at Dahlgren, referring to the maximum velocities that explosions can produce. A railgun could eventually send a 40-pound slug 200 miles in six minutes—10 times the range of the navy's primary surface support gun, the MK 45—and it could be used to support Marine troops engaged in land-based operations.

"A lot of people think a railgun is not going to make a lot of noise," Garnett says. "It's electrically fired, and they expect a whoosh and no sound." In reality, when the bullet emerges, it lets out a crack as electricity arcs through the air like lightning.

The railgun gets its name from two highly conductive rails, which form a complete electric circuit once the metal projectile and a sliding armature are put in place. When current starts flowing through the device, it creates a powerful electromagnetic field that accelerates the projectile down the barrel at 40,000 gs, launching it in a matter of milliseconds. Aerodynamic drag along with a million amps of current heats the bullet to 1,000 ^{o}C, igniting aluminum particles and leaving a trail of flame in its wake. The researchers estimate the muzzle energy based on the mass and velocity of the bullet in the barrel and from precisely timed x-ray snapshots during flight.

"What's important," says Garnett, "is that this is the first step on the way to building a tactically viable system with 64 megajoules of energy." [...]

DAHLGREN, Va. (Jan. 31, 2008) Photograph taken from a high-speed video camera during a record-setting firing of an electromagnetic railgun (EMRG) at Naval Surface Warfare Center, Dahlgren, Va., on January 31, 2008, firing at 10.64MJ (megajoules) with a muzzle velocity of 2520 meters per second. The Office of Naval Research's EMRG program is part of the Department of the Navy's Science and Technology investments, focused on developing new technologies to support Navy and Marine Corps war fighting needs. This photograph is a frame taken from a high-speed video camera. U.S. Navy Photograph

Figure C.157: Test firing of a modern railgun by the U.S. Navy in 2008.

BAE Systems. 2013. Electromagnetic (EM) Railgun.
[https://www.baesystems.com/en/product/electromagnetic–em–railgun]

We are honored to lead the way in the development of the Office of Naval Research (ONR) Electromagnetic (EM) Railgun Innovative Naval Prototype.

This fascinating technology, which uses high-power electromagnetic energy instead of explosive chemical propellants to launch projectiles farther and faster than any previous system, is currently in Phase 2 of the program. During this phase, we will advance the railgun by maturing the launcher and pulsed power from a single shot operation to a multi-shot capability. Auto-loading and thermal management systems will also be incorporated. We received a $34.5M contract from ONR in 2013 to pursue these efforts.

“We’re committed to developing this innovative and game changing technology that will revolutionize naval warfare,” said Chris Hughes, vice president and general manager of Weapon Systems at BAE Systems. “The Railgun’s ability to defend against enemy threats from distances greater than ever before improves the capabilities of our armed forces.”

On December 10, 2010, the U.S. Navy made history at the Naval Surface Warfare Center-Dahlgren Division with our Laboratory Railgun. A 33-Megajoule shot was fired, the energy equivalent of 110 nmi range. In 2012, during Phase 1 of the INP program, engineers at the Naval Surface Warfare Center successfully fired our EM Railgun prototype at tactical energy levels.

Not content with just merely building the launch platform, We are also pursuing the development of a Hyper Velocity Projectile (HVP). In late 2013, we received a $33.6 million contract from ONR to develop and demonstrate a HVP—a next-generation, guided projectile capable of completing multiple missions for the Electromagnetic Railgun, as well as existing 5-inch and 155-mm gun systems.

[Even nowadays, electromagnetic railguns are considered to be a high-tech “weapon of the future.” The best modern railguns are essentially just larger versions of Joachim Hänsler’s and Manfred von Ardenne’s 1944–1945 devices, and can now fire projectiles at approximately twice the velocity of Hänsler’s wartime railguns. Since Hänsler’s (and perhaps von Ardenne’s) detailed technical reports and even some of his equipment were brought back to the United States by the Alsos Mission, CIOS, and other teams of investigators in 1945, it appears that such modern railguns are directly derived from the wartime German work.

Much more archival research should be conducted to elucidate the history of electromagnetic railguns in the German-speaking world, as well as the impact of those innovators and innovations on postwar electromagnetic railguns in other countries.]

Appendix D

Advanced Creations in Nuclear Engineering

Der Welt Erbe gewänne zu eigen, wer aus dem Rheingold schüfe den Ring, der maßlose Macht ihm verlieh'.	The whole world can be possessed by one who from the Rhinegold forges the Ring, which can bestow immeasurable power.

Richard Wagner. 1854. *Das Rheingold.* Scene I. Wellgunde.

As discussed in Chapter 8, contributions by the German-speaking research world to fundamental nuclear science are very well documented.[1] Wilhelm Röntgen discovered X-rays in 1895, and Ludwig Zehnder was making detailed whole-body X-ray photos of humans by 1896. Hans Geiger and Walther Müller developed accurate radiation meter designs (Geiger counters or Geiger-Müller tubes) during the period 1908–1928 that are still in use today. Nuclear fission reactions were first proposed by Ida Tacke Noddack in 1934, and demonstrated and explained by Otto Hahn, Fritz Strassmann, Lise Meitner, and Otto Frisch in 1938–1939. Nuclear fusion reactions were proposed by Fritz Houtermans and his student Robert Atkinson in 1928–1929, and refined by Carl Friedrich von Weizsäcker and Hans Bethe in 1938. Detailed mathematical models of the nucleus, essential for accurately predicting nuclear decays and reactions, were first developed by von Weizsäcker in 1935 and ultimately finalized by Otto Haxel, Johannes Hans Jensen, Maria Goeppert Mayer, Hans Suess, and Eugene Wigner by 1949.

---

[1] See for example: Bethe 1991, 1997; Blatt and Weisskopf 1952; Brown and Lee 2006; Otto Hahn 1968; Irving 1967; L'Annunziata 2016; Nachmansohn 1979; Rife 1999; Schweber 2012; Sime 1996; Szanton 1992; Wigner 1967.

In contrast, progress toward nuclear engineering applications within the German-speaking research world is much less well understood by modern scholarship. Much of the relevant archival evidence has only been declassified and rediscovered in recent years, and was not publicly available when earlier historical assessments were made.[2] As presented in this appendix, the evidence that is now available demonstrates that wartime nuclear engineering programs in Germany were considerably larger and more advanced than has previously been generally understood. Some of the evidence even strongly suggests (but does not conclusively prove) that Germany may have developed and successfully tested fission bombs, and that it may have had a megaton-level hydrogen bomb in an advanced stage of development when the war ended.

For a much shorter overview than this appendix, see Section 8.8.

This appendix presents evidence of:

D.1. Flaws in the conventional historical view of the German program.

D.2. The fundamental scientific knowledge and planning of the program.

D.3. Sources of uranium and thorium.

D.4. Enrichment of uranium-235.

D.5. Fission reactors for breeding plutonium-239 and/or uranium-233.

D.6. Electronuclear systems for breeding plutonium-239 and/or uranium-233.

D.7. The production of other potentially nuclear-related materials.

D.8. Fission bomb designs.

D.9. Hydrogen bomb designs.

---

[2] With access to some of the previously unavailable former Soviet and East German archives and witness testimony, as well as newly discovered and released U.S. and British documents, beginning in the 1990s several authors argued (with varying degrees of success and accuracy—*caveat emptor*) that wartime German work on nuclear weapons was actually much more extensive, involved many more scientists, and progressed much further than had been accepted by the conventional historical narrative. See for example: Brooks 1992, 2002; Frank Döbert in *Walpersberg Geschichts- und Forschungsjournal* 2015, 2016; Eilers 2007, 2015; Fäth 1999, 2000; Fengler 2014; Fengler and Sachse 2012; *Geheimnis Jonastal* 2002–2024; Georg 2009; Henshall 1998, 2000, 2002; Hirschfeld and Brooks 1996; Hydrick 1998, 2016; Karlsch 2005, 2006, 2011; Karlsch and Laufer 2002; Karlsch and Petermann 2007; Karlsch and Zeman 2016; Mayer and Mehner 2001, 2002, 2004a, 2004b, 2009, 2010, 2016, 2019; Mehner 2004; Nagel 2003, 2011, 2012a, 2016; Oleynikov 2000; Petermann 2000; Schmitzberger 2004; Stevens 2007; Sulzer and Brauburger 2015; Matthias Uhl quoted in Schauka 2015; Wilcox 2019; Zeman and Karlsch 2008.

D.10. An October 1944 test explosion on the Baltic coast.

D.11. A circa November 1944 test explosion in Poland.

D.12. March 1945 test explosions in Thuringia.

D.13. Axis belief in the reality of German nuclear weapons.

D.14. Allied belief in the reality of German nuclear weapons.

D.15. Further research that is needed.

These claims may seem controversial. It is possible that the reports of wartime German nuclear weapons tests arose from tests of non-nuclear weapons (such as fuel-air explosives or chemical warfare agents), false wartime propaganda, or other factors. However, it is known that there were extensive and highly secretive nuclear programs in wartime Germany, that numerous military research and production sites were severely bombed by the Allies during the war and/or sanitized by the Germans at the end of the war, that Germans destroyed or hid large amounts of documents and research at the end of the war, and that Soviet, U.S., U.K., and French forces vacuumed up as many scientists and documents and as much equipment as they could find along the way. If the new evidence is indeed correct, one could understand why the Germans involved would have been loath to admit their deeds afterward for fear of being prosecuted as war criminals, or why any Allied forces that found secret evidence of German nuclear accomplishments would have preferred to claim those technologies and achievements exclusively for themselves.

The currently available evidence that is presented in this appendix does not conclusively prove that Germany successfully developed a nuclear weapon during the war. Nonetheless, the available evidence appears to be strongly suggestive of and highly consistent with that conclusion. Therefore, it is vitally important for researchers to thoroughly search all relevant government and personal archives in Russia, the United States, the United Kingdom, France, Germany, Austria, Czechia, Poland, Switzerland, Italy, the Netherlands, Belgium, Norway, Japan, and elsewhere to find additional documents that could fully elucidate the scope, history, and accomplishments of the wartime German nuclear program. Industrial archaeology and chemical analyses at sites where nuclear work may have taken place could also shed a great deal of light on the methods and results of the nuclear program.

D.1 Conventional Historical View of the German Program

[The conventional historical view that has been held since 1945 is that Germany was still trying to complete its first prototype fission reactor when World War II ended in Europe, and that Germany never even made a serious attempt to develop nuclear weapons.[3] This view is based on three categories of evidence, although each category has its own limitations as summarized below:

Evidence	**Limitations**
1. The U.S.-led Alsos Mission searching Germany for evidence of nuclear-weapons-related work at the end of the war found the incomplete fission reactor at Haigerloch, some papers on basic nuclear physics, and apparently not much else, according to the public accounts [Goudsmit 1945, 1947; Groves 1962; Pash 1969].	1. The Alsos Mission failed to properly investigate numerous specific organizations, scientists, and locations that could have revealed a more advanced nuclear program. If any more advanced nuclear work had in fact been discovered, that information would have been automatically classified at the time, and could remain classified or buried in archives and unreleased to this day.
2. Ten German nuclear scientists (Erich Bagge, Kurt Diebner, Walther Gerlach, Otto Hahn, Paul Harteck, Werner Heisenberg, Horst Korsching, Max von Laue, Carl Friedrich von Weizsäcker, and Karl Wirtz) rounded up by the Alsos Mission were kept under house arrest from July 1945 until January 1946 at Farm Hall in the United Kingdom, where their private conversations were recorded without their knowledge. The transcripts, which were not released to the public until 1992, record the scientists' surprise at news of the 6 August 1945 Hiroshima bombing and do not reveal significant apparent knowledge of nuclear weapons design and development [Bernstein 2001; Frank 1993; Hoffmann 2023].	2. A huge number of relevant nuclear scientists were not at Farm Hall. There is evidence that those who were there suspected surveillance and conducted their conversations accordingly. The preserved transcripts document only a small fraction of the discussions that would have occurred among ten people and their British attendants during those six months. Moreover, the transcripts are English translations, which may not accurately reflect the original German conversations. Both the original recordings and the original German transcripts are said to have been permanently lost, a shocking lapse for such an important operation.
3. In their public interviews and writings in the years after the war, German nuclear scientists professed a lack of desire, plans, materials and/or political support to produce nuclear weapons for the Third Reich [Cassidy 1992; Heisenberg 1953, 1971; Irving 1967; Powers 1993; NYT 1948-12-28 p. 10].	3. Only a small number of nuclear scientists went on the public record. It is not clear how much of what they said was factual history versus personal spin meant to avoid postwar criticism; the answer may vary for different scientists in question. Certainly it would have been in their best personal interests to downplay their support for weapons-related work as much as possible.]

---

[3] E.g., Goudsmit 1947; Hentschel and Hentschel 1996; Hoffmann 2023; Irving 1967; Powers 1993; Rose 1998; Walker 1989, 1995, 2020, 2024a, 2024b.

D.1.1 Alsos Mission

[Popular accounts of the Alsos Mission were written by Samuel Goudsmit, the scientific leader of Alsos, Boris Pash, the military leader, and Leslie Groves, their U.S.-based supervisor. In addition, many Alsos documents, long classified, are now available.

As illustrated by the documents in this section, the Alsos Mission failed to properly pursue a large number of leads that might have revealed that the German nuclear program was much larger and much more advanced than Alsos claimed. Some of the fundamental problems included:

- Whatever evidence Samuel Goudsmit wanted to pursue (or not), and whatever conclusions he drew from that evidence, apparently became the official view of Alsos. Boris Pash and other military men were there to move the Alsos scientists around safely and to retrieve any German scientists/materials that the Alsos scientists wanted, not to express their own opinions in Alsos reports. Likewise, there does not appear to be any documentation of junior Alsos scientists offering different opinions or disagreeing with Goudsmit through official channels.[4] Contemporary documents from U.S. officials show that they realized that Alsos basically was Goudsmit (pp. 3292–3293).

- Goudsmit was trained as a physicist, yet his only significant scientific accomplishment (calculations of electron spin) occurred when he was still a student, and it may have been due much more to his doctoral adviser Paul Ehrenfest and his fellow student George Uhlenbeck than to Goudsmit himself. Goudsmit was selected for Alsos specifically because he did not know or understand the scientific details of the Manhattan Project, in case he was captured by the Germans or the Russians. He spent his postwar career not as a scientifically innovative researcher, but rather as a bureaucratic administrator in scientific organizations who apparently concealed the fact that was a secret CIA asset (pp. 4778–4779).

- In his writings, Goudsmit appeared to show a strong belief in the superiority of his own insight and an equally deep prejudice against Germans, specifically a strong desire to believe that wartime German science and German scientists were inferior and incompetent. Almost certainly Goudsmit's mindset was strongly influenced by his parents having been killed during the war, although perhaps other factors influenced him as well. While his grief would be quite understandable, he did not sound at all like an open-minded and intellectually rigorous investigator for this topic, based on his own words. U.S. officials who worked with Goudsmit openly stated that he had a number of undesirable psychological characteristics (see for example pp. 3260–3261, 3264–3265, 3266–3269, 3274–3275, 3278, 3285–3287, 3288–3289, 3292–3293, 3294–3296, 3321).

- Goudsmit and other investigators incorrectly assumed that any significant details about the German nuclear program would be widely shared among German scientists and freely divulged by those scientists to Alsos investigators. Yet in fact the German program seems to have been highly compartmentalized, with each person knowing only as much as they needed to know to perform their own job in the program. Furthermore, it was in the best personal interests of any German scientists interviewed by Goudsmit to minimize their wartime knowledge, work, and accomplishments as much as possible, in order to avoid further interrogations, detention (at Farm Hall, Dustbin, Ashcan, in the United States, etc.), or war crimes trials that could lead to their imprisonment or execution. Thus they told Goudsmit exactly what he wanted to hear—that German science was inferior and had not accomplished much. Goudsmit was apparently very satisfied with that answer. Even if Goudsmit had been more open-minded, he had been trained as a physicist to hold academic discussions and to accept the answers at face value, not to hold strong, probing, skeptical interrogations and to apply as much psychological pressure as possible.

---

[4] Lt. Col. George R. Eckman's "Final Report on the ALSOS Mission," written in December 1945, seems to be missing from modern archives (p. 3333). If it could be located, it is possible that it might give a different opinion than Goudsmit's public statements.

- Goudsmit and the rest of Alsos never investigated work, personnel, equipment, or documents in the large and scientifically very important Soviet-occupied areas of Germany (apart from a token trip to the Kaiser Wilhelm Institute for Physics in Berlin in late July 1945, after the Soviets had already stripped it bare).

- Alsos never investigated other Soviet-occupied territory such as Poland, Czechoslovakia, Hungary, Romania, and Bulgaria, where considerable German work is known to have occurred (pp. 3271–3273).

- Alsos never investigated Norway and Denmark, where important German work had also been conducted.

- Alsos never investigated sites in Thuringia other than Stadtilm and Nordhausen, even though Thuringia was filled with a large number of potentially relevant sites, especially underground.

- Alsos did not seriously investigate Austria (apart from interviewing some scientists from Vienna, after the Soviets had already removed personnel and materials from Austria).

- Alsos dismissed and did not seriously pursue work that had been conducted by the Reichspost, Wilhelm Ohnesorge, Manfred von Ardenne, Fritz Houtermans, Siegfried Flügge, etc.

- Alsos dismissed and did not seriously pursue work that had been conducted by the Army Ordnance Office, Erich Schumann, Walter Trinks, etc.

- Alsos dismissed and did not seriously pursue work that had been conducted under the SS.

- Alsos did not seriously investigate work that had been conducted at I.G. Farben.

- Alsos did not consider the large number of German documents that were destroyed, hidden, or captured by other groups from the United States or from other countries (especially the Soviet Union).

- From the outset, Alsos was highly focused on a few German scientists such as Heisenberg who were already well known before the war. Alsos dismissed and did not seriously pursue other, newer, or previously unknown scientists and engineers that it encountered.

- Alsos stated incorrectly that German scientists had no concept for a bomb, other than a vision of a highly impractical and inefficient out-of-control fission reactor.

- Alsos stated incorrectly that German scientists had not given serious consideration to producing and using plutonium.

- Richard Kuhn was one of the top brains behind Germany's massive, long-running, and highly advanced chemical weapons program that successfully researched, developed, tested, mass-produced, and stockpiled the world's first nerve gases. Despite interrogating Richard Kuhn in April 1945, Goudsmit and the other Alsos investigators were completely oblivious to the existence of the nerve gas program or Kuhn's role in it. Even when they pressed Kuhn for more information in September 1945, all they learned was that he had been involved in the production of plastics and other basic materials (p. 3316). By that time Alsos had spent more than a year searching all of Europe for any evidence of any types of German weapons of mass destruction. This demonstrable and complete failure by Alsos to even discover (let alone properly understand) the massive German chemical weapons program appears to cast grave doubt on the competence of Goudsmit and the other Alsos investigators, as well as the validity of their conclusions about the German nuclear program, which involved many of the same organizations as the nerve gas program (Army Ordnance, SS, I.G. Farben, etc.).

- Before the war even ended, Goudsmit and/or his superiors apparently decided to divert most of the personnel, time, and resources of the Alsos Mission away from weapons of mass destruction (WMD), and instead to analyze other German technological developments such as anti-aircraft missiles and proximity fuses (e.g., pp. 3270, 3285, 3306). That shift is documented by the large number of reports that Alsos personnel wrote on those other subjects in spring and summer 1945. That effort duplicated non-WMD field work that was being carried out by many other teams of Allied investigators (BIOS, CIOS, FIAT, NavTecMisEu, etc.). It also left Alsos even less able to track down leads on German nuclear or other WMD programs. (Or perhaps it got Alsos out of the way so that some much more capable but more secretive Allied team could investigate the German nuclear program?)

- If Goudsmit concluded that there was no advanced German nuclear program, and stated that in official reports and public statements at the time, it would have been in his own best interests to keep saying that, even if he eventually learned otherwise sometime after the war. Goudsmit's ego about his own abilities, his prejudice against German scientists (including his bizarre lifelong personal fixation on Heisenberg), and his desire not to jeopardize his continuing U.S.-government-funded career and his public credibility would have been strong reasons for him to maintain his conclusions, even if sometime after the war he eventually heard some secret evidence that did not fit into his conclusions.

- In May 1945, SHAEF G-2 Generals Thomas J. Betts (p. 5030) and George Bryan Conrad plus AAF General Henry Arnold's advisor Prof. Edward L. Bowles of MIT (pp. 4711, 5319) concluded that Alsos had failed to do its primary job of investigating the German nuclear program (pp. 3285–3287). Robert Furman admitted that there were so many German nuclear sites and documents that his team did not even try to investigate them.

If there was in fact an advanced German nuclear program and the United States learned of that during or after the war, that knowledge does not appear to have flowed through or been shared with the Alsos Mission. Any such knowledge seems to have resided with whatever officials or groups warned Franklin Roosevelt of an advanced German nuclear program; directed advancing U.S. forces straight to Thuringia, Austria, and Czechoslovakia; captured and interrogated Hans Kammler; handled the personnel and materials from the German submarine U-234 and other captured submarines; etc. (see p. 4692).]

[According to Robert Furman, "everything done by Alsos was done by Goudsmit" (p. 3292). Other than the brief mention by Thomas Powers below, why do the many books on the Alsos mission completely omit the fact that in early December 1944, long before Allied forces even reached Germany, Samuel Goudsmit went on such an extreme tirade against German people that he had a nervous breakdown, was relieved of duty, and was sent back to the United States for most of the remainder of the war in Europe? That seems like an important detail in evaluating the history of the Alsos mission and the quality of its work in investigating the German nuclear program.]

Thomas Powers. 1993. *Heisenberg's War: The Secret History of the German Bomb.* New York: Alfred A. Knopf. pp. 371–372, 382, 560.

Robert Furman wasn't quite sure what brought it on—war causes terrible pressures. They'd been out in Strasbourg that day, had suddenly found themselves in a field surrounded by howitzers right at the edge of the war. Back at headquarters they'd seen some victims of shell shock, trembling, weeping men. Goudsmit had been terribly worried about his parents; he'd heard nothing since their final letter of farewell in March 1943, and the news of Eindhoven in September promised no hope.

That night in Strasbourg, when Furman and Goudsmit were alone together, Goudsmit "just went off his rocker—he was furious at the Germans, weeping and thrashing around."[13] It took Furman half an hour to pull Goudsmit together. Goudsmit barely alluded to this episode when he wrote his wife from Paris four or five days later. "The grim part of the venture," he told her, "was that I had to face for the first time a small number of people like myself, but on the other side." He told her he longed for a visit home, and Furman quietly arranged it. Goudsmit had been working closely with Furman for some months on what he had described to Walter Colby as "Major RRF's project for Germany," and Furman had planned to send Goudsmit to Switzerland to lay the groundwork. But the episode in Haagen's apartment in Strasbourg ended all that; it seemed obvious to Furman that Goudsmit was not up to the tension or the delicacy of such an effort. [...]

[O]n November 20, Donovan and Buxton cabled Dulles, "Am told Goudsmit somewhat tactless and possibly should not be included to work with temperamental people. Wardenburg said to be the better informed." But Goudsmit remained a part of the plan until mid-December, when his name abruptly disappeared from operational cables after his strange breakdown under the strain of Strasbourg. [...]

13. Interview with Furman, March 6, 1990.

William Donovan to Allen Dulles. 20 November 1944. Cable Out 23415. [NARA RG 226, Entry A1-134, Box 219, Folder 1371: OUT AZUSA Nov. '43 Sept. '45]

#0857. AZUSA. 110 from 109 and 106. Answering your #0747 and #737 to Paris.

If Furman and Wardenburg are pressing to contact Flute [Paul Scherrer] and others recommend:

A. Preliminary discussions be held with you and [Moe] Berg always present.

B. If later meetings can be held over until about December 15th, [Martin] Chittick can be present and carry through for long control as your special representative. Am told Goudsmit somewhat tactless and possibly should not be included to work with temperamental people. Wardenburg said to be the better informed.

[See p. 3261. According to OSS Director William Donovan, Samuel Goudsmit was "tactless," not recommended to work with people, and even less "informed" about nuclear weapons physics than Frederic Wardenburg, a junior Alsos member and middle manager from Du Pont whose only scientific education was a bachelor's degree in electrical engineering from two decades earlier (1927).]

If Furman and Wardenburg are pressing to contact Flute and others recommend:

A. Preliminary discussions be held with you and Berg always present.

B. If later meetings can be held over until about December 15th, Chittick can be present and carry through for long control as your special representative. Am told Goudsmit somewhat tactless and possibly should not be included to work with temperamental people. Wardenburg said to be the better informed.

10 January 1945

Passed to Lansdale

Colonel W. M. Adams
Chief, Foreign Branch
Military Intelligence Service
War Department
Washington, D. C.

Dear Bill:

This letter will cover only one subject, but an important enough subject to justify special consideration. I am writing to you in this informal manner because of a feeling that the subject may be considered outside of my responsibilities, yet it is my feeling that it is not a field that should be a matter of discussion between myself and my immediate chief.

As I have tried to indicate on my last trip to Washington, it is my opinion that our scientific group has not been properly organized and lacks leadership As a result of this, we have had a number of difficulties, not only in the administrative field but also in the fact that some people whose interests we are covering considered it necessary to advise and even direct our technical and administrative personnel on matters pertaining to the Mission. This last phase was always handled satisfactorily in the past and we have not given it too serious consideration. But it does show that proper leadership in the scientific field was necessary.

Upon the departure of Dr. Goudsmit, and lacking a man designated by him to take over the responsibilities, I called a meeting, inviting Dr. Reid, Captain Roop, Captain Cromartie, Mr. Wardenburg and the administrative officers to attend. At this meeting we discussed the various fields of activity and the need for periodical meetings of this nature in order to coordinate the activities of all groups concerned. This idea was concurred in by all and we have since had another meeting.

In the absence of Dr. Goudsmit, Dr. Reid has been asked to serve as the acting chief of the scientific group. This action was taken because no assistant was designated by Dr. Goudsmit.

We see evidence of immediate results, following the above action. Dr. Reid has started organizing the past information and experience of the Mission in order to be able to give a brief but thorough orientation to the newly arrived scientists so that they do not feel lost or neglected when first arriving and are able to coordinate their needs and interests with the general procedure adopted by the Mission. He has also commenced a detailed study of all available information on German targets in order to dovetail such information with operational planning. The few days that he has engaged in this activity have already brought positive reactions and it is my opinion that it has also improved the morale of the scientists.

Ltr to Colonel W. M. Adams - continued 10 January 1945

Dr. Reid expects to remain until Dr. Goudsmit's return. I hope that OSRD will be contacted and asked to approve the appointment of Dr. Reid as acting head in Dr. Goudsmit's absence. An official communication informing the War Department of this action has been dispatched with Captain Blake.

In talking over this same matter with Dr. Waterman, I have indicated that in my opinion, Dr. Sherwood would be an excellent man to serve as a scientific coordinator, The man serving in that capacity does not have to have knowledge of the languages, Prime requisites should be administrative and organizational abilities. Dr. Reid has already demonstrated that, and from what I know of Dr. Sherwood, I am sure that he could carry on the work started by Dr. Reid. The only reason I am not considering proposing Dr. Reid is because of his statement that he must return to the States on or about 1 February 1945.

The above in no way is criticism of Dr. Goudsmit's work. As I told Dr. Waterman, the extremely heavy load in connection with the one field of interest of Dr. Goudsmit, has made it practically impossible for him to devote any time to the general organizational work, and what is more important, has created a lack of interest in any other work. At the same time, I do not feel that the man doing the organizational work and general coordinating work of the Mission should be carrying the load and the responsibility as a deputy of a man who will not have any interest in that field. It is therefore my strong recommendation that Dr. Goudsmit be put in charge of all the work in Major Furman's field of interest and another man, preferably Dr. Sherwood or a man with his capabilities be designated as coordinator of the scientific group or chief of the scientific group. I am sure that this would improve our Mission considerably and it is my opinion that such action would be strongly favored by the Navy contingent.

Please accept this informal note as an expression of opinion on my part and it is dispatched only because of my feeling that we are not ready to operate in Germany and that the lack of readiness is not due to our failure to prepare operational plans, but simply because we can lay no plans without information on which to base them. I am now working out plans for operations in Germany and, as I stated above, Dr. Reid has been extremely helpful in getting from the available scientists such information as I need to organize my work.

With best personal wishes,

Sincerely,

BORIS T. PASH,
Lt. Colonel, MI

Figure D.3: Boris Pash to W. M. Adams. 10 January 1945. Selection of a replacement chief scientist of Alsos after Samuel Goudsmit's nervous breakdown and removal [NARA RG 77, Entry UD-22A, Box 169, Folder 32.7002 GERMANY—ALSOS MISSION ∗ Administrative Matters (1940–1945)].

A. E. Britt to Francis J. Smith. 7 March 1945. SUBJECT: Conversation between Col. Lansdale and Dr. Harold Wilson [NARA RG 77, Entry UD-22A, Box 169, Folder 32.7002 GERMANY—ALSOS MISSION ∗ Administrative Matters (1940–1945)]

1. Col. Lansdale talked to Dr. Tolman and the latter stated that Dr. Harold Wilson was concerned about the complaints received from Goudsmit. This apparently is the recent letter of which you are cognizant. Col. Lansdale told Dr. Wilson—

a. That we are not concerned with the organization of Alsos in the Theater;

b. This organization [Alsos] is not responsible for TA in the Theater, however that Furman and our organization is and that it is up to us to determine what we want, and how much of what they have obtained that we want and the priority to be established;

c. That it was none of Goudsmit's business as to whether or not the reports were sent to Dr. Tolman. Goudsmit is inclined to want to write reports and direct them to scientists. He was told that it was his responsibility to write reports in a way that non-scientists could understand them inasmuch as this office is the using office.

2. There is some question as to whether or not the above points contradict the basic principles of the Alsos agreement. However in talking to Dr. Wilson, Col. Lansdale pointed out to him that we did not think such as the case.

3. Suggest you talk to Col. Lansdale regarding the above matter.

BRITT

[See document photo on p. 3265.

Goudsmit complained about many other people, and many other people complained about Goudsmit's behavior and performance.

For some other examples, see pp. 3260–3261, 3266–3269, 3274–3275, 3278, 3285–3287, 3288–3289, 3292–3293, 3294–3296, 3321.

Quarrelsome behavior so severe as to leave such a paper trail was quite unusual for a senior scientific "professional," and certainly would have been detrimental to the proper functioning and the quality of the results of a high-priority intelligence mission being conducted in the midst of a world war.]

Vannevar Bush to Samuel A. Goudsmit. 15 March 1945. [NARA RG 77, Entry UD-22A, Box 169, Folder 32.7002 GERMANY—ALSOS MISSION * Administrative Matters (1940–1945)]

There were several matters which you discussed with Dr. Waterman and Mr. Wilson, prior to your return to the ETO, relating to the activities of the ALSOS Mission on behalf of the Special Project. Subsequent discussion of these matters with Dr. Tolman and Lt. Col. Lansdale have, I believe, clarified the points which were on your mind and resulted in bringing these matters into satisfactory form. Undoubtedly since you have now returned, you will be conferring with Major Furman and Major Calvert and the scientific members of ALSOS who are concerned with this subject and will presently have a full picture of the situation as it now stands in the ETO.

One point which I believe you felt needed clarification concerned the action which you and your colleagues should take in regard to the execution of plans for gathering intelligence in this area, which might be requested from Washington and alter materially the priorities and plans already agreed upon by the military and scientific group in the ETO. I do not anticipate that such situations are likely to arise, but if this were to occur, I understand it was your feeling that you would be satisfied if you were assured that any major changes were reviewed by and concurred in by Dr. Tolman. I am assured by Dr. Tolman and Colonel Lansdale that such will be the case. I expect that you will find upon your return that plans for targets and priorities are fairly well agreed upon and details have been worked out to the extent possible with available data. I understand that these plans have been closely coordinated with the requirements and information available in Washington. I expect that these plans are now clear enough so that there is little likelihood of important differences of opinion.

Another matter which has been discussed with Dr. Tolman and Colonel Lansdale concerns the nature of the intelligence reports which you prepare relating to the Special Project. We can give you full assurance that all of these reports are available to Dr. Tolman and reach him. As to the matter of writing them in "lay language," this writing must be done either in the ETO or here. If your reports are not received in such form someone here, namely Dr. Tolman, would have to re-write them in a form understandable to the non-scientific group. This is a burden which Dr. Tolman cannot take on nor can his staff. Hence we feel that it is reasonable to ask that your group prepare these reports in a form directly useable by the military group. Moreover, such reports can best be prepared with the full information available in the ETO rather than attempt to expand abbreviated scientific reports.

On the matter of interviewing German scientists taken into custody and sent to this country, this comes under two headings; firstly, interviewing for information on the Special Project; and secondly, interviewing for information in other fields. As to the first, it is Colonel Lansdale's group which can arrange the interviews. As to the second, it is a matter for Colonel Adams to arrange, for it is a G-2 function, and I understand that Dr. Waterman is taking this up with Colonel Adams. As to the PW's described in your memorandum, it is the conclusion of Colonel Lansdale's group, with which Dr. Tolman concurs, that the marginal material on the Special Project which might be obtained from these men, in addition to that already obtained by you and your colleagues in the interviews in the ETO, is not sufficiently promising to warrant the risks involved in giving them more information which might result from further interviews on this subject. Dr. Waterman will advise you of the results of his discussion with Colonel Adams regarding interviews for the purpose of obtaining information on other subjects.

I believe that you have found upon your return that the organization of intelligence on the Special Project from the military side has been clarified since your departure in December, and I trust that matters will progress smoothly during the remainder of this important and interesting assignment. I also hope that the targets will soon be available and that the circumstances, planning and execution of the missions will permit achieving results which are up to the Strasbourg standard. I am sure that all groups concerned will exert their best efforts to bring about this result.

Very sincerely yours,

V. Bush, Director

cc: General Groves
Dr. Tolman
Dr. Waterman

[See document photos on pp. 3268–3269.

Vannevar Bush, who ran all wartime U.S. R&D, apparently agreed with all of the concerns about Goudsmit. Bush's letter to Goudsmit was diplomatically phrased but undoubtedly severe.

Goudsmit had been ordered out of Europe from December 1944 until sometime in March 1945, and Alsos wrapped up most of its duties by early May 1945. Thus Goudsmit spent very little time in Europe during the critical final six months of the war.]

Subject: Targets.

To : Major F. J. Smith, Room 5119, New War Dept. Bldg., Washington, D. C.

1. The US Strategic Bomb Survey group has made plans to send target teams into Russian occupied enemy countries. Lt. Col. Ralph Colbert of that group advised Capt. Davis that a list of targets has been submitted to the Russians as well as a list of the names of those persons who will compose the target teams. The teams will number ten and will each consist of seven technically qualified persons.

2. An examination of their target list failed to disclose any in which we have a common interest. However, some of their targets are located in the same towns as ours e.g. Oranienburg.

3. Lt. Col. Colbert was asked if we might assign men to the target teams and replied that due to the nature of the agreement this is not feasible. He stated however, that, if we desired, arrangements might be made whereby we can brief members of their teams. He emphasized that under no circumstances would any investigations be pursued at any places other than those specifically covered by the agreement.

4. This trip of the Bomb Survey group is independent of C.I.O.S. activity and it is planned to undertake this operation as soon as arrangements with the Russians are completed.

5. We believe that by sending one of our men along on this mission we would undoubtedly acquire information of some value as to the possibilities of future operations in Russian controlled territory. However, it does not seem probable that we would gain any TA information on this venture and therefore it is thought that we would not be warranted in sending a man in at this time. Your views on this matter are requested.

This report seems a bit "fuzzy" to me—the arrangement (indentation, e. g.,) doesn't clarify the meaning for me.

R.

I imagine Goudsmit's talking thru 'is 'at when he says certain Targets are to be REMOVED from TA list—on what ground? Freiburg, e. g., he hasn't been there that I know of.

[Handwritten:] Major Smith has read.

[See document photos on p. 3275.

Even officers who were supporting Goudsmit's activities were exasperated by his penchant for declaring that no significant nuclear (TA) evidence could exist at certain places without even bothering to visit or investigate them. According to them, Goudsmit was known for "talking through his hat," a colloquial British phrase for talking about something without understanding it at all.]

Copy No. 1 of 5 Copies

18 April 1945

SUBJECT: Preliminary Report on TA Information Obtained at Stadtilm

1. General:

a. Though all secret files were removed from Stadtilm, there remain about seventy German file folders with very revealing correspondence and new target information.

b. We have examined much of this on the spot for information affecting our immediate operations.

c. Although the material will be subjected to further study at our headquarters it will obviously be impossible to deal adequately with all of it.

2. Targets to be removed from TA list.

a. Freiburg.

b. Posthalde bei Hinterzarten in the Black Forest.

c. Miersdorf bei Zeuthen, where the Reichspost worked.

d. Gottow

e. Berlin

f. Oranienburg, Auer.

All the above places have been evacuated as far as TA Targets are concerned.

3. Targets to be added.

a. Haigerloch, about 10 miles west of Hechingen. The pile is in the rockcellar of the Inn Zum Schwanen, also described as under the church and as "Schwanenkeller". Also at Haigerloch is the group under Philipp, which used to be in the Black Forest (Posthalde-Hinterzarten).

b. Celle, north of Hannover, in the "Mitteldeutsche Spinnhütte A.G." (Spinning Mill) where Groth has set up the centrifuge from Freiburg since November.

c. Hamburg, Harteck is back at the University there.

4. Active TA Groups

a. As of 26 February 1945 (five) only of the following groups were importantly engaged on the project for the "derivation of energy from nuclear processes":

Arbeitsgruppen KWI (Physik und Chemie) (Berlin, Heidelberg, Hechingen, Tailfingen) des Bevollmächtigten in Stadtilm, Haigerloch, München

Prof. Harteck (Inst. Phys. Chem. Hamburg, Celle and Anschutz und Co)

Prof. Kirchner - Brof. Riezler (Phys. Inst. Köln, Zwstelle Garmisch-Partenkirchen)

Phys. Inst. Wien (Prof. Stetter)

Strahlenschutz und Dosimetrie (PTR und KWI Berlin-Buch)

Vorhaben SH200 (besonders I.G. and Bamag-Meguin)

Spezialmetallfertigung (Auer, Degussa)

Zyklotron (KWI Heidelberg, Siemens-Halske)

Elektronenschleuder (Betatron) gemeinsam mit RuK

These are in the highest priority group, "Fuhrernotprogramm" copied from a letter from Gerlach to the Kriegswirtschaftsstelle RFR.

5. Interrogation of Berkei (additional).

a. Dällenbach works on a "betatron" in Bisingen. (SAG is not sure that Berkei is correct, though correspondence files show that Berkei held a responsible position in Gerlach's organization).

b. Gerlach is most likely in München.

c. Schüler is in Hechingen.

d. The place to which Diebner and most of his personnel were taken is not known. That it was Hechingen is merely a guess.

e. The party leader who watches over nuclear physics according to rumors, and who is blamed for the kidnapping of Diebner et al. is called Standartenführer Sievers. No details, only rumors.

f. The SS has its own research department (Waffenamt) under a General Professor Schwab.

- 2 -

~~SECRET~~

~~SECRET~~

g. Information from enemy countries was insufficient because German intelligence did not use technically qualified people. In charge was, for this field, a Dr. Fischer, Referent Für Wiss. Erkundungen. One time address Prinz Heinrichstrasse, Berlin. They were told that the U.S.A. made its own heavy water. (Their code name is SH200) and that we were successful at separating 235 in kilograms.

6. Evaluation.

We are more convinced that the German TA effort is small.

However, nowhere have we found the real secret progress reports. Nor have we found copies of an existing secret magazine, called "Geheime Berichte" or "Kernphysikalische Berichte". These can only be found in a rapid surprise move.

S. A. GOUDSMIT

SUBJECT: TA Security

10 May 1945

1. The attempt to keep German TA activities secret is bound to be without success for a number of reasons.

a. Too large a group of German physicists of various degrees of prominence are familiar with the work.

b. Too many copies of their "secret" publications are in existence and will be found eventually.

c. Personnel and laboratories from which information about the German effort can be obtained are spread all over Germany and will be found, investigated and reported upon by the several investigating teams which are covering Germany. The best laboratories on the project are in Berlin and in the Hechingen area, covered by Russian and French intelligence.

d. It will be impossible to maintain full security in the U.S.A. after the war because of the number and type of people involved, who will be dispersed all over the U.S.A. as well as over parts of Europe.

2. The destruction of the Haigerloch laboratory was at least unnecessary and does not assure TA security. It was destroyed without the knowledge or advice of the Scientific Chief of ALSOS.

3. It is recommended that:

a. German TA scientists be returned to Germany.

b. That they be permitted to pursue small-scale TA experiments (U-Machine).

c. That such experiments be restricted to two or three laboratories situated in American and British occupied territory, or in Denmark and the Netherlands.

Figure D.13: Samuel Goudsmit. 10 May 1945. SUBJECT: TA Security [NARA RG 77, Entry UD-22A, Box 169, Folder 32.7002 GERMANY—ALSOS MISSION ∗ Administrative Matters (1940–1945)]. Even Goudsmit said that Alsos was far too small compared to the number of other Allied investigators and the size of the German nuclear program to conduct a proper investigation. Note that Goudsmit missed out on the Haigerloch site, the greatest "success" of Alsos.

Sean Longden. 2009. *T-Force.* p. 193, citing TNA FO800/565 or some other TNA document???

Among the 106 targets investigated by T-Force in the ruins of Hamburg were some that related to nuclear research. They included the laboratory of the nuclear physicist Dr Paul Harteck, an associate of Dr Groth. In May 1945, his detention caused some controversy, since he was picked up by a specialist team with an interest in nuclear research [Alsos] that was working within the 21st Army Group's area. This team had been operating without notifying T-Force HQ or coordinating their activities with T-Force teams in the field. As a result, the atomic research team's work within the British zone was temporarily suspended and similar teams were withdrawn from the area. The issue was rectified when the team in question agreed to abide by existing operational orders. [...]

Upon arriving back in Germany, Dr. Groth discovered that the centrifuge needed for his work was missing. Investigations carried out by T-Force HQ revealed that the centrifuge had been disassembled and sent to SHAEF for the attention of the Operation Alsos mission. It was one of the few examples of evacuations that had been unsuccessful. The hurried nature of the work and the involvement of outsiders, added to the importance of the research equipment, meant that the standard procedures had not been followed. Due to an administrative oversight, no serial number had been issued and the shipment was untraceable. Dr. Harteck was later informed that the centrifuge was unlikely to be located...

[The Alsos Mission was officially reprimanded and removed from the field for behaving improperly and/or finding things they should not have. Apparently they also carelessly lost (or perhaps confiscated and deliberately concealed?) a highly important advanced uranium gas centrifuge prototype.]

Subject: Information on German TA Project which is still Missing.

MEMORANDUM to Major Francis J. Smith.

1. Reports on D_2O ice pile (1944).

2. Heisenberg report on 1944 Gattow layer experiments.

3. Heisenberg reports on semi-technical pile ($1\frac{1}{2}$ ton D_2O plus 3 tons U.)

4. Detailed reports on work in industrial laboratories, to wit: Hex preparation methods used by I. G., catalyst preparation for heavy water exchange by Leuna, and details of Uranium metal by Degussa and Auer.

5. Riehl of the Auer Company has not been recorded as captured. It is possible that the Auer Company carried on work on separation which was not reported on by Clusius.

6. Interview with Heisenberg most unsatisfactory. Heisenberg's stock of reports should be uncovered if at all possible. Questioning of Heisenberg should endeavor to find out whether any work was begun on fast chains to implement Flugge's 1942 research plan.

7. Investigation of German intelligence files on -

   a. State of their knowledge of our project.

   b. State of their knowledge of Russian project.

Karl Cohen

KARL COHEN

Figure D.19: Karl Cohen to Francis J. Smith. 19 May 1945. Subject: Information on German TA Project which is still Missing [NARA RG 77, Entry UD-22A, Box 166, Folder 32.22-1 GERMANY—Research—TA—(1943–June 1946)]. As this document demonstrates, even for the fairly small number of people and sites that Alsos focused on, they failed to collect a great deal of important information.

Robert Furman to John Lansdale. 22 May 1945. [NARA RG 77, Entry UD-22A, Box 168, Folder 202.2 LONDON OFFICE: Combined Intell Disc.]

Boris [Pash] left here for home to try to convince authorities that the Alsos job is over. But in this theater, [General Thomas J.] Betts, [General George Bryan] Conrad and [MIT Professor Edward L.] Bowles are not agreeing that the job for which Alsos was set up to do is in any way completed. More scientists have now arrived. Proximity fuzes, BW [biological warfare] and NACA [aerospace] investigations are now absorbing the energies of Tarryton equipment and personnel.

A great many TA [tube alloy = nuclear] reports still remain in Germany, as you know. Therefore, reports on installations are received weekly about which we do very little. We always try to pick papers that are reported to exist, to remove them from circulation but it is impossible to keep other agencies from finding out about the German effort. For instance, in Osenberg's files, was found some of the essential reports which you had taken back to the States.

[See document photos on pp. 3286–3287.

According to Robert Furman, in May 1945, three very senior and extremely well-informed U.S. intelligence officials concluded that Alsos had failed to do its primary job of investigating the German nuclear program:

- SHAEF intelligence (G-2) General Thomas J. Betts (see pp. 5028–5030).
- SHAEF intelligence (G-2) General George Bryan Conrad.
- AAF General Henry Arnold's advisor Prof. Edward L. Bowles of MIT (see pp. 4711, 5319).

Robert Furman admitted that there were so many German nuclear sites and documents that his team did not even try to investigate them.]

Dear Jack: Lansdale

Transport material

This letter will help bring you up to date on happenings here.

be confirmed.

The Hildesheim operation is virtually complete. Materials on this day should be on board boat headed for a port in the London area.

Lt. Warner left for LeHavre today with the materials we have collected in Germany. He will escort these materials to America the latter part of this week. He will call General Groves upon his arrival in the states. The materials are marked for shipment to Major Kelley at his New York address, as directed. You will be advised by wire what date Lt. Warner can be expected in the states.

Nearly all TA documents in the hands of Alsos have been shipped to London and I anticipate closing this TA Alsos office about 1 June. Harteck's files were shipped by Major Bullock to Washington.

Diebner is returning with Major Bullock. We found it best to release him if we can get Toepel.

Major Calvert has released Sgt. Connerton for a job at Oak Ridge providing a replacement is forthcoming. Can you wire about the replacement so we can get Connie started home.

to Le Havre, presumably & to Kelley – 39 bbls {4 kept / 35 low} "HARTZ ACID"

One shipment, the heavy water from the Hartz mountain region, will follow Lt. Warner separately. I have an escort available.

After you left, Harteck was found and Dr. Goudsmit considers him one of the most interesting and certainly the most able technically of the group.

Albers will be located and questioned. A report will be rendered on him possibly next week. He will be detained with the others if his part in the program seems interesting or important enough.

The casual search made through Harteck's records here has shown that there is certain to be counter-intelligence information of value in the records you already have in Washington. For instance, Albers evidently received some fragmentary news of the effort being made in the United States. A report on this will be obtained from him. While I haven't heard of what you are doing with those records, I assume you have Lane, Fine, Sherwood and others busy analyzing the files. Let us know what is being done with these records so that we can tell Perrin progress.

important

The guests have been a problem since your departure because of the severe criticism the theater has received on the handling of prisoners and detained personnel. I have tried not to make any arrangements that can later be questioned. This appears to be done now since General Groves dropped his interest in comforts for these people. I am trying to do these people as well

as I can while still remaining well within the covering directives. I expect to take up with Perrin, in London when I see him this week, plans for keeping these Germans busy. Plenty of reading material will be given them. Plenty of paper and pencils will be made available. Ideas from Washington are invited.

Believe we should be getting out of Alsos with an open door policy set up so that Calvert can call upon them to assign Tarryton personnel and equipment if necessary on affairs he directs. Calvert intends to use other means in every possible instance, I am sure, but you can understand how difficult it sometimes is to get the facilities needed to do a job quickly and discreetly and for this reason Alsos facilities should be available. Lt. Colonel Eckman was ordered not to give personnel and I would suggest immediate clearance by wire after conversation with Adams and Pash.

We have asked for Lt. Toepel. Please wire me immediately on him as I need him now. Oates is covering for Toepel until you get Boris to release him. Due to Pash's interpretations on our completed target work, Eckman won't even lend him to me. If you wish, we will look for someone else to avoid difficulties but we know Toepel is briefed and able. I believe his is the best solution.

What is the answer on the request by cable for a set up in the American Embassy, Paris? Calvert prefers the Embassy to Com Z.

Dr. Goudsmit has great interest in and by now a very complete knowledge of the German effort. He has asked me if somehow he can continue to work with us. Both Calvert and I believe Sam has done a fine job and should be used. I believe Sam could be a part of Calvert's staff on duty in Paris and by continuing his contacts and memberships in all the various intelligence organizations here, he could continue a very essential service toward security and counter-intelligence.

Alsos position here now is complex. I might write you what I see happening, but it all results in confirming our present policy of hands off and no participation in their re-organization. Boris left here for home to try to convince authorities that the Alsos job is over. But in this theater, Betts, Conrad and Bowles are not agreeing that the job for which Alsos was set up to do is in any way completed. More scientists have now arrived. ~~Precision~~ PROXIMITY fuzes, BW and NACA investigations are now absorbing the energies of Tarryton equipment and personnel.

A great many TA reports still remain in Germany, as you know. Therefore, reports on installations are received weekly about which we do very little. We always try to pick up papers that are reported to exist, to remove them from circulation but it is impossible to keep other agencies from finding out about the German effort. For instance, in Osenberg's files, was found some of the essential reports which you had taken back to the states.

Jay is bound to get word of the American detention of Heisenberg, etc. soon. Can you answer our cable on this point?

I had no difficulty in arranging the Joachimstahl trip.

Please save any boxes I send to you for me, against the forces of the office counter-scroungers.

My plans will be to return to the states between 1 June and 5 June unless I hear from you that a change in my plans would be desirable. I would like to know if any reports will be required, so that I can prepare them here from files with which I am acquainted. This might make it possible for me to get some leave upon my return.

Bob Furman

Figure D.21: Robert Furman to John Lansdale. 22 May 1945. SHAEF G-2 Generals Thomas J. Betts (pp. 5028–5030) and George Bryan Conrad plus AAF General Henry Arnold's advisor Prof. Edward L. Bowles of MIT (pp. 4711, 5319) concluded that Alsos had failed to do its job. Furman admitted that there were so many German nuclear sites and documents that his team did not even try to investigate them [NARA RG 77, Entry UD-22A, Box 168, Folder 202.2 LONDON OFFICE: Combined Intell Disc.].

Samuel Goudsmit to George Eckman. 7 June 1945. [NARA RG 77, Entry UD-22A, Box 166, Folder 32.24-2 GERMANY: Research—Res. Inst. & other Facilities (May 45–Dec 46)]

1. I request that this document and all attachments [from Hans Martin on uranium gas centrifuges] be handed over to Major Furman at once. They are an excellent example of the type of TA information which is picked up by other agencies and finally arrives in our hands.

2. At the end of the report, the conceited German makes certain demands which may impress the Military Government. I request that you send through the proper channels the following information:

> a. The intelligence in connection with the scientific work of Professor Martin of Kiel has been completely covered by information and documents obtained elsewhere.
>
> b. His own activities are considered relatively insignificant and do not warrant any special action or privileges.

3. I think this information should reach the hands of all those who had anything to do with this case.

[See document photo on p. 3289. Hans Martin developed advanced uranium gas centrifuges (pp. 3517–3528). Alsos never visited Martin and discouraged other investigators from doing so (p. 3281, grade C). When Martin gave documents to other investigators, Goudsmit confiscated them and strongly discouraged further examination of Martin or his centrifuges.

Without ever even meeting Hans Martin or seeing his uranium gas centrifuges, Goudsmit labelled Martin just another example of "the conceited German," declared the uranium gas centrifuges "relatively insignificant," and broadcast those conclusions to other agencies to try to prevent any further discussions of the topic. Thus this letter illustrates three aspects of Goudsmit's personality that shine through in many of his writings:

1. A raging prejudice against all Germans, including those he had never even met.
2. An obsessive need to keep claiming his own intellectual superiority over other people (especially career scientists such as Hans Martin, Werner Heisenberg, and many others who made much more important scientific discoveries and inventions than Goudsmit did in his lifelong career as a government bureaucrat).
3. Abuse of the power of his U.S.-government-granted position to harm other people, even people he had never met or interacted with, simply to gratify his own impulses.

Goudsmit's behavior had already led to a four-month removal from duty as well as meetings and letters of reprimand (e.g., pp. 3260–3269, 3321), yet as shown in this letter, he persisted in that behavior even after he was reinstated.

Goudsmit's behavior was highly counterproductive for the work that he was expected to perform: conducting a detailed investigation of the German nuclear program. In this particular case, Goudsmit, who had no expertise with any uranium enrichment methods whatsoever, succeeded in suffocating the U.S. government's interest in German uranium gas centrifuges. Ultimately those centrifuges proved to be so much more efficient than the U.S.'s own methods of uranium enrichment that they dominated the global market and drove the U.S. enrichment facilities out of business (pp. 3549–3553).]

James A. Lane to Francis J. Smith. 16 June 1945. [NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)]

Attached is presented an overall summary of the German nuclear physics work obtained from an analysis of the captured technical and correspondence files. The previous indication given by the Strassburg report that the German nuclear physics project was only a "Class B" enterprise is verified in all respects by this more complete set of documents. It is apparent that the German scientists and military leaders early in the war abandoned hope for a military application of nuclear physics, but at the same time realized that it would be a mistake for Germany to fall behind other countries in the field. Their project was therefore developed on a scale approximately comparable to a normal peace time enterprise. According to Berkei the nuclear physics project cost a total of 15,000,000 marks ($1,500,000) in the period 1940–1945. A rough estimate gives the following distribution of costs:

Cost of uranium metal	$200,000
Cost of heavy water	100,000
High voltage apparatus and cyclotrons	500,000
Experimental work and salaries 1940–42	150,000
” 1943	200,000
” 1944	300,000
” to May 1945	50,000
	$1,500,000

These figures should be considered only as qualitative evidence of the emphasis on various phases of the German project since the captured financial reports are not complete enough for a more accurate determination of expenditures.

[See document photo on p. 3291. Friedrich Berkei, a junior scientist working on small fission pile experiments, gave his personal rough estimate of the total cost of those experiments that he knew about (or was willing to admit to Allied investigators that he knew about): 15 million marks.

Authors from Samuel Goudsmit (p. 3298) onward have falsely represented that as the total cost of the entire wartime German nuclear program.

The true total cost of the program would have to include work at a large number of organizations (p. 5109) and sites all over Europe (from Norway to East Prussia to Bulgaria to Portugal), as demonstrated by the documents in the rest of this appendix.

An analogous situation would be asking a junior scientist helping with Enrico Fermi's Chicago pile experiments to give a personal rough estimate of the cost of those experiments, then claiming that that estimate was the total cost of the entire Manhattan Project. No credible scholar would do that. Likewise no credible scholar should claim that Berkei's estimate is the true total cost of the entire wartime German nuclear program. (This criticism is not directed at James Lane, who was merely filing a field report recounting what Berkei had told him.)]

NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)

Figure D.23: James A. Lane to Francis J. Smith. 16 June 1945 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)]. Friedrich Berkei, a junior scientist working on small fission pile experiments, estimated the total cost of those experiments that he knew about (or admitted knowing about): 15 million marks. Authors from Samuel Goudsmit onward have falsely represented that as the total cost of the wartime German nuclear program, which actually included a large number of organizations and sites all over Europe.

W. A. Consodine to Leslie Groves. 12 July 1945. Intelligence Setup in Europe. [NARA RG 77, Entry UD-22A, Box 168, Folder British–U.S. Relations on Atomic Energy Intelligence (War Period) to 8 Oct 1945]

1. In a discussion with Major Furman I learned his ideas as to the Intelligence setup in Europe as you requested me. He thinks there should be a study of German research in Tube Alloys and industrial research and also of personnel. He thinks that now is the time to do it in Germany. He also believes that all reports of all other U.S. and U.K. agencies should be correlated as quickly as possible.

2. He says that there is no one in Paris now and someone should be there who reads and speaks German, who has a knowledge of the project, who is field grade in rank, preferably Lieut. Colonel, who can work with Spears, Oaks and Davis, etc.

3. He commented that there are a lot of T.A. reports in various American channels now. He thinks that Goudsmit is the ideal man to do the German job in Paris. He mentioned that he has a personality difficulty. He, however, said that Goudsmit is the one who did the job for Alsos and that everything done by Alsos was done by Goudsmit. He said the British respect Goudsmit.

4. He mentioned that Welsh was insecure and a braggart. He substantiated previous statements that he is anti-American. He said that Gattiger is hard to control but all right. He stressed that we must start right away, that if we do not we will lose the advantages we can get out of the transition period.

5. He concluded that the man or men you use must have the following qualifications: (1) knowledge of American and British scientific war groups (2) rank (3) know the project (4) be able to handle prima donna scientists and prima donna military officers.

[See document photo on p. 3293.

If the German nuclear program was as small and accomplished as little as Alsos reported, why did Robert Furman recommend that a detailed study of the German nuclear program's research, industry, and personnel be conducted in July 1945, after Alsos had basically already wrapped up its mission and (officially at least) already learned everything important about the German program?

Recall that in a 22 May 1945 letter, Furman had privately admitted that there were so many German nuclear sites and documents that his team did not even try to investigate them (p. 3287).

In addition to the reports written by Alsos, there were "a lot of T.A. reports in various American channels" as of July 1945. Furman also referred to "all reports of all other U.S. and U.K. agencies" on the subject. Who wrote all of those other reports, and where are the reports now?

Similarly, in his 22 May 1945 letter, Furman had written that there were so many German nuclear sites and documents that "it is impossible to keep other agencies from finding out about the German effort" (p. 3287).

According to the document above, Furman explicitly stated that Samuel Goudsmit had "a personality difficulty" and that "everything done by Alsos was done by Goudsmit."]

Figure D.24: W. A. Consodine to Leslie Groves. 12 July 1945. Intelligence Setup in Europe [NARA RG 77, Entry UD-22A, Box 168, Folder British–U.S. Relations on Atomic Energy Intelligence (War Period) to 8 Oct 1945]. Robert Furman explicitly stated that Samuel Goudsmit had "a personality difficulty" and that "everything done by Alsos was done by Goudsmit."

Samuel Goudsmit to Reginald C. Augustine, 18 September 1945. [NARA RG GOUDS, Entry UD-7420, Box 6, Folder Rosbaud]

1. It is still of primary importance to Alsos and to other intelligence agencies to locate Professor (or General) Erich Schumann about whom I have written you before. Recently, a new lead on this man was discovered in Berlin by Major Clark. I believe it is definitely worthwhile to follow it up. The contact in Berlin may actually know where Schumann is. I propose that Rosenberger go to Berlin to squeeze the information out of him, or at least as much as can be obtained. Schumann is supposed to be in Bavaria somewhere. At one time, we sent Previti down to find some of Schumann's disciples. He returned without any information about Schumann. I think this angle should be pushed a little harder after Rosenberger returns from Berlin.

2. Here follow the details: The man in Berlin in Professor Erhard Landt, born 22 June 1900. He was Dozentenbundsführer and Dozentenschaftsleiter of Berlin University where he was a professor of physical and chemical technology and an honorary professor of physics. His present address is Berlin-Schmargendorf, Königsallee 67, British Zone. Landt was interrogated by Major Clark and Pfc. Strauss. Major Clark was interested in finding a man by the name of Rudi Schall who, at one time, worked with Schumann. Major Clark made it appear that Schall might be useful on a job in the U.S.A. At that suggestion, Landt intimated that he knew that Schall was in Bavaria, that Schumann was there also, that Schumann was the better man and that he (Landt) might be able to contact him.

3. I wish that Rosenberger would pick up this lead as if he came from Major Clark [i.e., lie] and, in that way, obtain Schumann's location.

4. I should like to point out again that Schumann, though he had a very high position, is regarded by all scientists, including old and competent German scientists, as definitely a second-rater. We even possess a Gestapo evaluation of him, mentioning that he was incompetent and not possessing the right character for the job he was holding. The fact that Landt praises him very much proves that he is also an incompetent charlatan. Landt was very much surprised that Clark had found him. He is a cagey, unreliable man who asks more questions than he gives out information. If everything fails, there may be enough reasons to have him detained. I have a feeling that he was an ardent supporter of the party. If Rosenberger needs any assistance in Berlin, he might contact Dr. P. Rosbaud who has been exceedingly helpful to us so far. Rosenberger can tell him what he is after—he knows about it. He has also helped Major Clark. His last known address was Boltzmannstrasse 1. He is keeping in contact with G-2 of Group CC whose office is at Boltzmannstrasse 20. If Rosenberger is successful in Berlin, the information obtained should be followed up immediately by a trip to Bavaria. Even if it is not successful, someone should once more go back on the trail which Marti Previti tried to follow and use some forceful inducements on those fellows to find their boss. I return herewith one copy of Previti's report.

[See document photo on p. 3296.

To the modern reader, Samuel Goudsmit's tone and message throughout this letter are truly shocking. This does not sound like a professional business letter written by a well-known theoretical physicist or a diligent government investigator. It sounds more like an organized crime boss ranting about someone he hates and then ordering all of his goons to use extreme measures to track down that person and deal with him.

Erich Schumann designed and apparently built fission implosion bombs during the war (pp. 4185–4277, 4640–4664, 4257–4259).

When Alsos finished its major operations in May 1945, it had not located Schumann, but it strongly recommended that other investigators do so (p. 3280, grade A). In this letter, Goudsmit sounded willing to go to any lengths to find Schumann. This letter also mentioned past and planned future attempts to locate Schumann.

Schumann appears to have hidden with various friends in Germany until summer 1947, when he was given official sanctuary in the British-controlled zone of Germany in exchange for information and/or work that U.K. officials considered sufficiently valuable to shield Schumann from the United States and from the ongoing war crimes trials. See pp. 4910–4911.

Despite all of this evidence about Schumann's wartime work on sophisticated nuclear weapon designs and despite Goudsmit's months-long frantic searches for Schumann, Goudsmit knowingly gave false testimony to the United States Senate by claiming that Schumann's "main interest was the physics of piano strings" (p. 3297). Goudsmit repeated this deliberate falsehood in his 1947 book, *Alsos* (p. 3317).

Goudsmit even included some gratuitous slander in this letter, seemingly oblivious to the fact that it was clearly disproven by the very request he was so urgently making in the letter.

Without providing any evidence, Goudsmit claimed that any person who "praises" Schumann's work "proves that he is also an incompetent charlatan." By Goudsmit's definition, such incompetent charlatans must then include the Allied investigator Major J. C. Clark mentioned in Goudsmit's letter (p. 4190), the U.S. Army Ordnance Department (p. 4187), the British government (pp. 4910–4911), the Soviet government (p. 4642), Max Planck (p. 4910), Wernher von Braun after the Apollo 11 moon landing (1984), and even Alsos itself (p. 3280, grade A).

Goudsmit claimed that a Gestapo evaluation proved that Schumann was incompetent. Actually Schumann was one of Heinrich Himmler's top scientific advisors, and the United States was well aware of that fact after the war (p. 3393).

What were the "other intelligence agencies" to whom it was of "primary importance... to locate... Schumann"? CIC, OSS, or otherwise? Even without explicitly identifying them, this is a written admission by Samuel Goudsmit that U.S. government organizations that were not Alsos were also doing an official (and probably more thorough) investigation of the wartime German nuclear program.]

S. A. GOUDSMIT
Scientific Chief

NARA RG GOUDS, Entry UD-7420, Box 6, Folder Rosbaud

Figure D.25: Samuel Goudsmit to Reginald C. Augustine, 18 September 1945: "It is still of primary importance to Alsos and to other intelligence agencies to locate Professor (or General) Erich Schumann about whom I have written you before" [NARA RG GOUDS, Entry UD-7420, Box 6, Folder Rosbaud]. Schumann designed and apparently built fission implosion bombs during the war (pp. 4185–4277, 4640–4664, 4257–4259). When Alsos finished its major operations in May 1945, it had not located Schumann but recommended that other investigators do so (p. 3280, grade A). See p. 4190 for Major Clark.

Samuel Goudsmit's 6 December 1945 testimony to the U.S. Senate. *Hearings Before the Special Committee on Atomic Energy, United States Senate, Seventy-Ninth Congress, First Session, Pursuant to S. Res. 179, a Resolution Creating a Special Committee to Investigate Problems Relating to the Development, Use, and Control of Atomic Energy, Part 2, December 5, 6, 10, and 12, 1945.* Washington, D.C.: U.S. Government Printing Office, 1946. [Goudsmit 1945]

In spite of certain preliminary newspaper reports, we can say that the Germans did not have anything at all. They were way behind. They just did not have the vision which the Allied scientists had, I believe.

[...] For instance, as I mentioned before, the German scientists seem to have lacked the vision. They did not believe in its success from the very beginning. They knew its importance, and were convinced that the project was important; but they did not believe that it could be done within a reasonable time, 50 to 100 years. [...]

Himmler's SS men went around and spread the rumor that very soon the Germans were going to use a uranium bomb, scaring the scientists who knew they were 50 or a hundred years away from such a goal.

Other reasons why the Germans did not make any real progress were probably, as I mentioned before, that the key men in administrative positions were utterly incompetent. For instance, Army Ordnance had as its chief advisor on military matters a second-rate physicist named Schumann, like the musician Schumann. In fact, his main interest was the physics of piano strings. [...]

That man had a small project going on in one of the Army proving grounds near Berlin, and the scientists he had working with him were definitely inferior compared with the scientists which were available in Germany for such a project; so there was one group working.

There was another group working in the so-called Kaiser-Wilhelm Institute for physics. [...]

A private scientist, Baron von Ardenne, a clever technician and businessman, got the Minister of Post and Telegraph, Ohnesorge, interested in his research. Ohnesorge was near to Hitler and kept the Fuehrer informed about the importance of the project. For awhile, Von Ardenne was considered by the German authorities to be the expert on the uranium problem, much to the dismay of the really competent scientists. [...]

At the beginning of 1945, most of the research was still in practically the same state as it had been in 1943. Isotope separation had been tried on a very small scale only by means of a centrifuge. [...]

Some of the key scientists worked only part time on this important research and the rest of the time did routine teaching or administrative work. The lack of proper large-scale facilities necessary for this kind of work was, of course, another reason for the lack of success.

At the slow pace at which they were progressing, it is obvious that German scientists did not believe a bomb would be constructed within the course of the war. They were confident that perhaps a uranium machine, or at least its basic principles, could be obtained within a reasonable length of time. It is remarkable, however, how incomplete their knowledge was. They were, according to their research reports, scarcely aware of some of the basic difficulties which they were likely to encounter in their efforts. Most surprising is the fact that not even their best scientists had given any thought to the use of plutonium.

Attempts were made to have German chemical industry produce heavy water because the Norwegian plant had been destroyed. However, not much progress was made with this plan either. [...]

The effort was small, though it had the highest priority among all scientific research projects in Germany. The total expenditure was about 15,000,000 marks, which is perhaps equivalent to some $10,000,000. The appropriation for 1944–45 was 3 ¼ million marks with a subsequent supplement of 1,000,000.

It is estimated that approximately 100 scientists were active on this project. They were divided into several rather small groups working on different phases of the problem and were spread all over Germany. [...]

Toward the end of the war, the German experiments had indicated that it was possible to obtain an increase in the number of neutrons, but no self-sustaining neutron source had been constructed as yet. [...] Gerlach was quite upset when, shortly afterward, the S. S. spread rumors that the Germans were soon going to use a uranium bomb. The scientists knew that they were still a hundred years away from that goal.

Himmler's S. S. had begun to take an active interest in research and especially in the uranium project. This organization had threatened to evacuate key scientists and their equipment to the Bavarian redoubt where they would be forced to complete the work under pressure. To the relief of the frightened German scientists, this plan failed, probably because of the rapidity of the German collapse. Only one group was actually kidnapped by the S. S. and let loose in Bavaria.

But, the German scientists believed in their superiority. They attempted to hide their research reports and all information about their work from Allied investigators—of course, in vain.

Not until they learned about the use of the atomic bomb by the Allies did they realize how far behind they were. They had lost not only the military war, but also the war of science.

[Samuel Goudsmit knowingly and repeatedly gave completely false testimony to the United States Senate, as shown by many documents from Alsos's own files, including but not limited to those on:

- Erich Schumann and his implosion bomb experiments (e.g., pp. 3280, 3296, 4190).
- Manfred von Ardenne's calutron (all of Section D.4.3, especially p. 3562).
- Reports on plutonium from Ida Tacke Noddack (pp. 3795–3794), Carl Friedrich von Weizsäcker (pp. 3800–3807), Fritz Houtermans (pp. 3814–3823), Otto Hahn (p. 3825) and Josef Schintlemeister (pp. 3794, 3827–3830).
- The fact that the 15,000,000 marks only covered a small set of fission pile experiments and was not at all the total cost of the wartime German nuclear program, which included a large number of organizations and sites all over Europe (p. 3291).
- The German nuclear program being too large for Alsos to even investigate more than a small fraction of it (e.g., pp. 3271–3273, 3279–3283, 3285–3287, 3292–3293).
- SHAEF G-2 Generals Thomas J. Betts (p. 5030) and George Bryan Conrad plus AAF General Henry Arnold's advisor Prof. Edward L. Bowles of MIT (pp. 4711, 5319) concluding that Alsos had failed to do its primary job of investigating the German nuclear program (pp. 3285–3287).
- Statements by knowledgeable participants that German nuclear weapons were ready or nearly ready by the end of the war and that would have been known to Alsos (e.g., pp. 4186–4190, 4275–4277, 4396–4419, plus many documents in Sections D.13 and D.14).

Goudsmit repeated most of these false claims in his 1947 book and other writings.

In view of this overwhelming evidence that Samuel Goudsmit was a serial fabulist, scholars and journalists must treat Goudsmit and any information derived from him accordingly.]

Questions from Senator Edwin Johnson during Samuel Goudsmit's 6 December 1945 testimony to the U.S. Senate. ***Hearings Before the Special Committee on Atomic Energy, United States Senate, Seventy-Ninth Congress, First Session, Pursuant to S. Res. 179, a Resolution Creating a Special Committee to Investigate Problems Relating to the Development, Use, and Control of Atomic Energy, Part 2, December 5, 6, 10, and 12, 1945.*** **Washington, D.C.: U.S. Government Printing Office, 1946, p. 254. [Goudsmit 1945]**

Dr. GOUDSMIT. [...] The total effort expended by the Germans on the project was rather small, but it was among the scientific projects the one of the highest priority; still it was very small compared to our effort.

Senator JOHNSON. In your investigation of the German effort, did you have access to all of the efforts of Germany? Press reports have inferred, or at least I have understood from them, that certain German efforts had been taken over by the Russians, and that such plants as they took over were not open to inspection.

Now, did you have access to all the plants in Germany, and when you speak of what the Germans did, are you speaking of everything that the Germans did in the Russian-occupied zone as well as in the American-occupied zone?

Dr. GOUDSMIT. I speak with confidence of everything the Germans did on the atomic bomb project. I am certain that I have inspected all the papers and have talked to all the key men on the project, and have seen all the documents and most of the laboratories have been visited by me or by men who worked in connection with me.

Senator JOHNSON. In the Russian-occupied as well as in the American- and British-occupied zones? Have you visited any Russian-occupied laboratories?

Dr. GOUDSMIT. I think that is classified information.

Senator JOHNSON. You cannot testify on that?

Dr. GOUDSMIT. I cannot testify in open session as to that.

[From this exchange, it appears that Goudsmit had additional information about the German nuclear program that he was unwilling to share with the U.S. Senate. What exactly was that information?

Alternatively, was Goudsmit simply bluffing the U.S. Senate? If providing honest answers to Senator Johnson's questions would have revealed that Goudsmit had failed to pursue many important leads, did Goudsmit evade Johnson's questions by falsely claiming that the answers were "classified information" that he could not discuss?]

STATEMENT OF DR. S. A. GOUDSMIT, PROFESSOR OF PHYSICS, UNIVERSITY OF MICHIGAN

The CHAIRMAN. Dr. Goudsmit, have you a prepared statement?

Dr. GOUDSMIT. I have no prepared statement with me, but I may have one later.

I wish to point out first of all that my connection with the atomic bomb is quite different from that of the previous witnesses. I have not worked on the project at all, except in intelligence functions.

I was connected with the War Department mission which was sent overseas in order to find out what the German progress was along the project of the atomic bomb, and that was what we have done, and that is the information which I can give you.

Also, because of that function, I may have a few suggestions which might be useful, even though they are one-sided suggestions, as to control and supervision.

In spite of certain preliminary newspaper reports, we can say that the Germans did not have anything at all. They were way behind. They just did not have the vision which the Allied scientists had, I believe.

I have put down a few points about the German progress.

The German scientists had abandoned the hope of making a bomb during this war, entirely. They used the idea of the bomb to sell it to the Government and to the military officials.

Another point is that as a result they concentrated their efforts on the production of atomic energy, and all the work done was nothing else but trying to build what is called over here a pile, a uranium machine. That is all they worked on, and they had not even succeeded in constructing a pile. They had not a working uranium machine.

At the end of the war they had done just enough experimentation so that they were certain that it could be done, but they had not done it. They had not produced a chain reaction. They had not a uranium machine which they had hoped for.

The total effort expended by the Germans on the project was rather small, but it was among the scientific projects the one of the highest priority; still it was very small compared to our effort.

Senator JOHNSON. In your investigation of the German effort, did you have access to all of the efforts of Germany? Press reports have inferred, or at least I have understood from them, that certain German efforts had been taken over by the Russians, and that such plants as they took over were not open to inspection.

Now, did you have access to all the plants in Germany, and when you speak of what the Germans did, are you speaking of everything that the Germans did in the Russian-occupied zone as well as in the American-occupied zone?

Dr. GOUDSMIT. I speak with confidence of everything the Germans did on the atomic bomb project. I am certain that I have inspected all the papers and have talked to all the key men on the project, and have seen all the documents and most of the laboratories have been visited by me or by men who worked in connection with me.

Senator JOHNSON. In the Russian-occupied as well as in the American- and British-occupied zones? Have you visited any Russian-occupied laboratories?

Dr. GOUDSMIT. I think that is classified information.

Senator JOHNSON. You cannot testify on that?

Dr. GOUDSMIT. I cannot testify in open session as to that.

The remarkable thing about the Germans is that all the time they believed that they were ahead of our effort along those lines. Not until the news broke that the atomic bomb had been dropped did they realize that they were not ahead, but that they were behind. They were absolutely convinced that their work was ahead of ours.

They had no knowledge of our project, none whatsoever, except a few incorrect statements from their intelligence department, and some rumors which they did not take seriously. There was, in 1943, a rumor that in America scientists were working on an atomic bomb, but all details were lacking, and so it was not taken seriously. It was merely used as a means to have the authorities give more help, more men, more space for the laboratories. That was all they used it for.

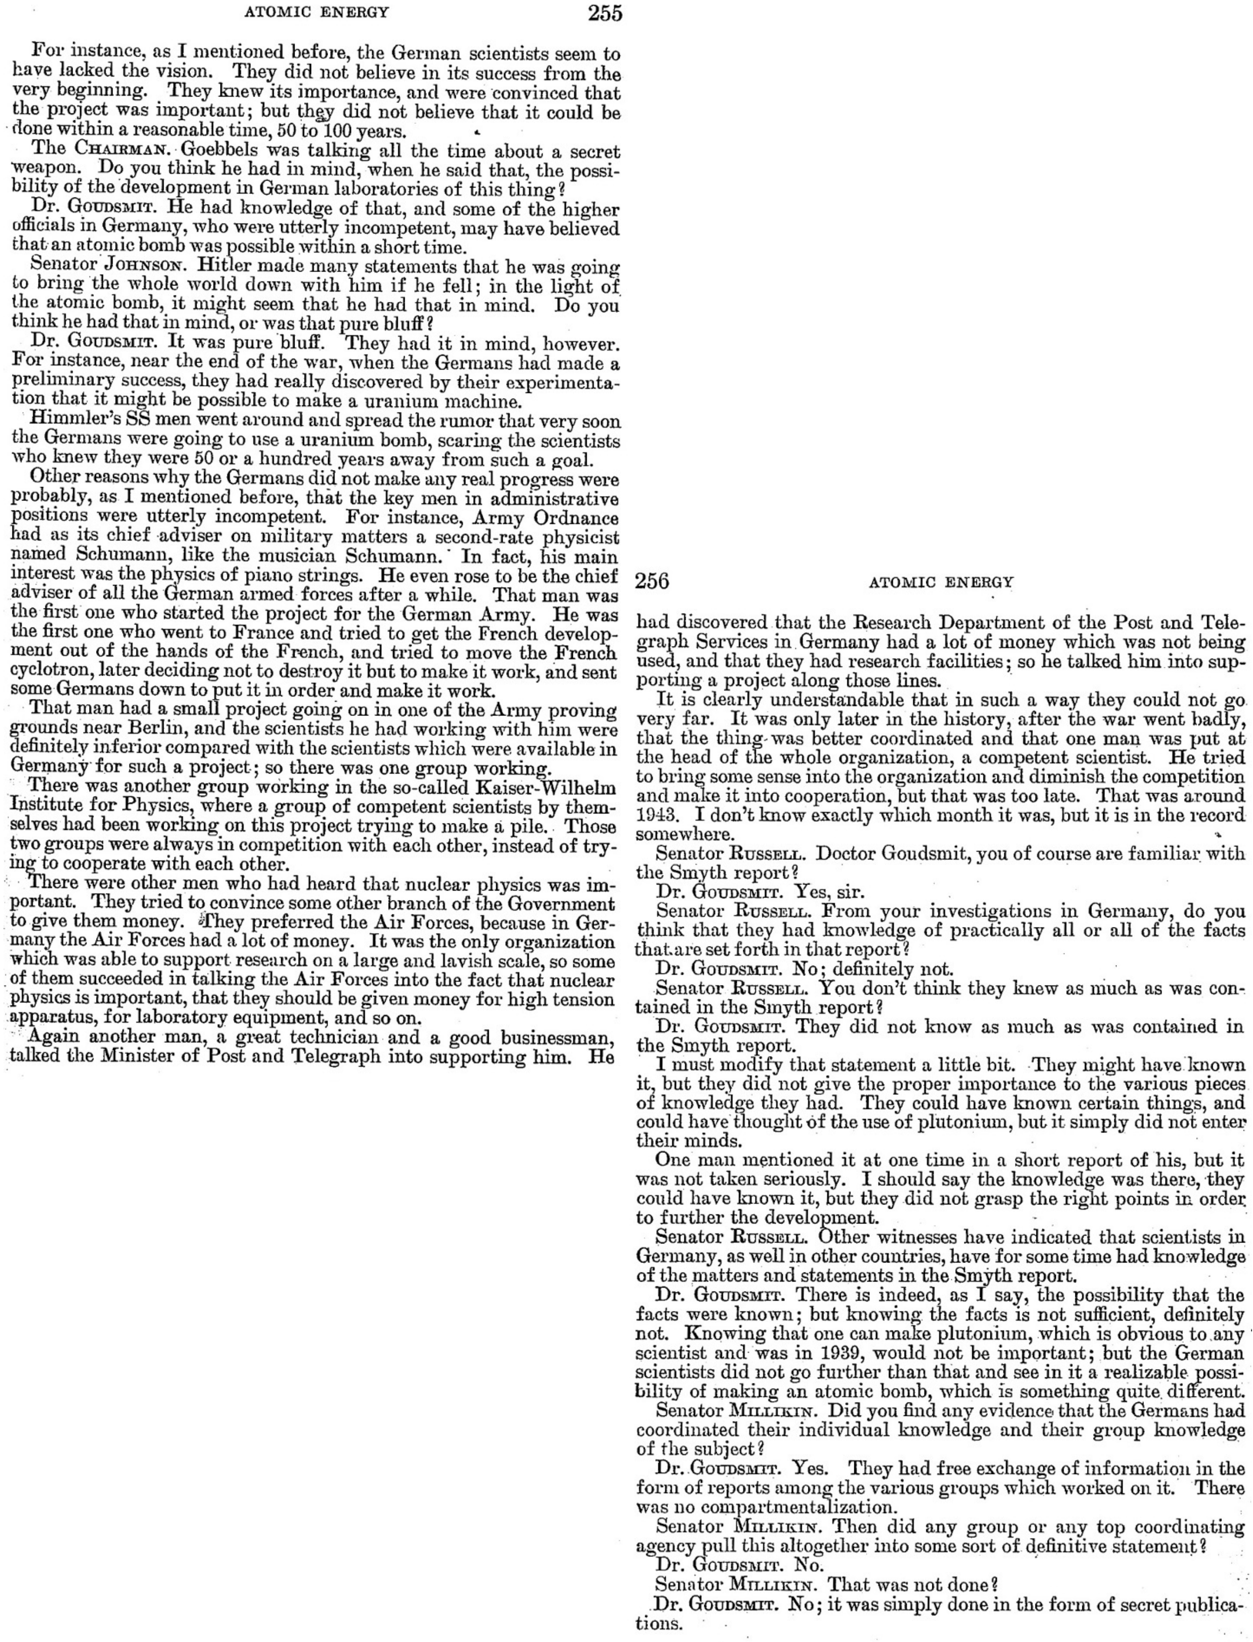
Senator RUSSELL. You state that their work was very narrow in scope. Do you gather from this that it had not gotten beyond the laboratory stage?

Dr. GOUDSMIT. It had not gotten beyond the laboratory stage.

Senator MILLIKIN. They did not even have a pilot plant?

Dr. GOUDSMIT. They did not have even a pilot plant. The reason for the lack of progress in Germany, as I see it, can be again put down in a number of points.

Figure D.26: Samuel Goudsmit's 6 December 1945 testimony to the U.S. Senate [Goudsmit 1945].



ATOMIC ENERGY 255

For instance, as I mentioned before, the German scientists seem to have lacked the vision. They did not believe in its success from the very beginning. They knew its importance, and were convinced that the project was important; but they did not believe that it could be done within a reasonable time, 50 to 100 years.

The CHAIRMAN. Goebbels was talking all the time about a secret weapon. Do you think he had in mind, when he said that, the possibility of the development in German laboratories of this thing?

Dr. GOUDSMIT. He had knowledge of that, and some of the higher officials in Germany, who were utterly incompetent, may have believed that an atomic bomb was possible within a short time.

Senator JOHNSON. Hitler made many statements that he was going to bring the whole world down with him if he fell; in the light of the atomic bomb, it might seem that he had that in mind. Do you think he had that in mind, or was that pure bluff?

Dr. GOUDSMIT. It was pure bluff. They had it in mind, however. For instance, near the end of the war, when the Germans had made a preliminary success, they had really discovered by their experimentation that it might be possible to make a uranium machine.

Himmler's SS men went around and spread the rumor that very soon the Germans were going to use a uranium bomb, scaring the scientists who knew they were 50 or a hundred years away from such a goal.

Other reasons why the Germans did not make any real progress were probably, as I mentioned before, that the key men in administrative positions were utterly incompetent. For instance, Army Ordnance had as its chief adviser on military matters a second-rate physicist named Schumann, like the musician Schumann. In fact, his main interest was the physics of piano strings. He even rose to be the chief adviser of all the German armed forces after a while. That man was the first one who started the project for the German Army. He was the first one who went to France and tried to get the French development out of the hands of the French, and tried to move the French cyclotron, later deciding not to destroy it but to make it work, and sent some Germans down to put it in order and make it work.

That man had a small project going on in one of the Army proving grounds near Berlin, and the scientists he had working with him were definitely inferior compared with the scientists which were available in Germany for such a project; so there was one group working.

There was another group working in the so-called Kaiser-Wilhelm Institute for Physics, where a group of competent scientists by themselves had been working on this project trying to make a pile. Those two groups were always in competition with each other, instead of trying to cooperate with each other.

There were other men who had heard that nuclear physics was important. They tried to convince some other branch of the Government to give them money. They preferred the Air Forces, because in Germany the Air Forces had a lot of money. It was the only organization which was able to support research on a large and lavish scale, so some of them succeeded in talking the Air Forces into the fact that nuclear physics is important, that they should be given money for high tension apparatus, for laboratory equipment, and so on.

Again another man, a great technician and a good businessman, talked the Minister of Post and Telegraph into supporting him. He had discovered that the Research Department of the Post and Telegraph Services in Germany had a lot of money which was not being used, and that they had research facilities; so he talked him into supporting a project along those lines.

256 ATOMIC ENERGY

It is clearly understandable that in such a way they could not go very far. It was only later in the history, after the war went badly, that the thing was better coordinated and that one man was put at the head of the whole organization, a competent scientist. He tried to bring some sense into the organization and diminish the competition and make it into cooperation, but that was too late. That was around 1943. I don't know exactly which month it was, but it is in the record somewhere.

Senator RUSSELL. Doctor Goudsmit, you of course are familiar with the Smyth report?

Dr. GOUDSMIT. Yes, sir.

Senator RUSSELL. From your investigations in Germany, do you think that they had knowledge of practically all or all of the facts that are set forth in that report?

Dr. GOUDSMIT. No; definitely not.

Senator RUSSELL. You don't think they knew as much as was contained in the Smyth report?

Dr. GOUDSMIT. They did not know as much as was contained in the Smyth report.

I must modify that statement a little bit. They might have known it, but they did not give the proper importance to the various pieces of knowledge they had. They could have known certain things, and could have thought of the use of plutonium, but it simply did not enter their minds.

One man mentioned it at one time in a short report of his, but it was not taken seriously. I should say the knowledge was there, they could have known it, but they did not grasp the right points in order to further the development.

Senator RUSSELL. Other witnesses have indicated that scientists in Germany, as well in other countries, have for some time had knowledge of the matters and statements in the Smyth report.

Dr. GOUDSMIT. There is indeed, as I say, the possibility that the facts were known; but knowing the facts is not sufficient, definitely not. Knowing that one can make plutonium, which is obvious to any scientist and was in 1939, would not be important; but the German scientists did not go further than that and see in it a realizable possibility of making an atomic bomb, which is something quite different.

Senator MILLIKIN. Did you find any evidence that the Germans had coordinated their individual knowledge and their group knowledge of the subject?

Dr. GOUDSMIT. Yes. They had free exchange of information in the form of reports among the various groups which worked on it. There was no compartmentalization.

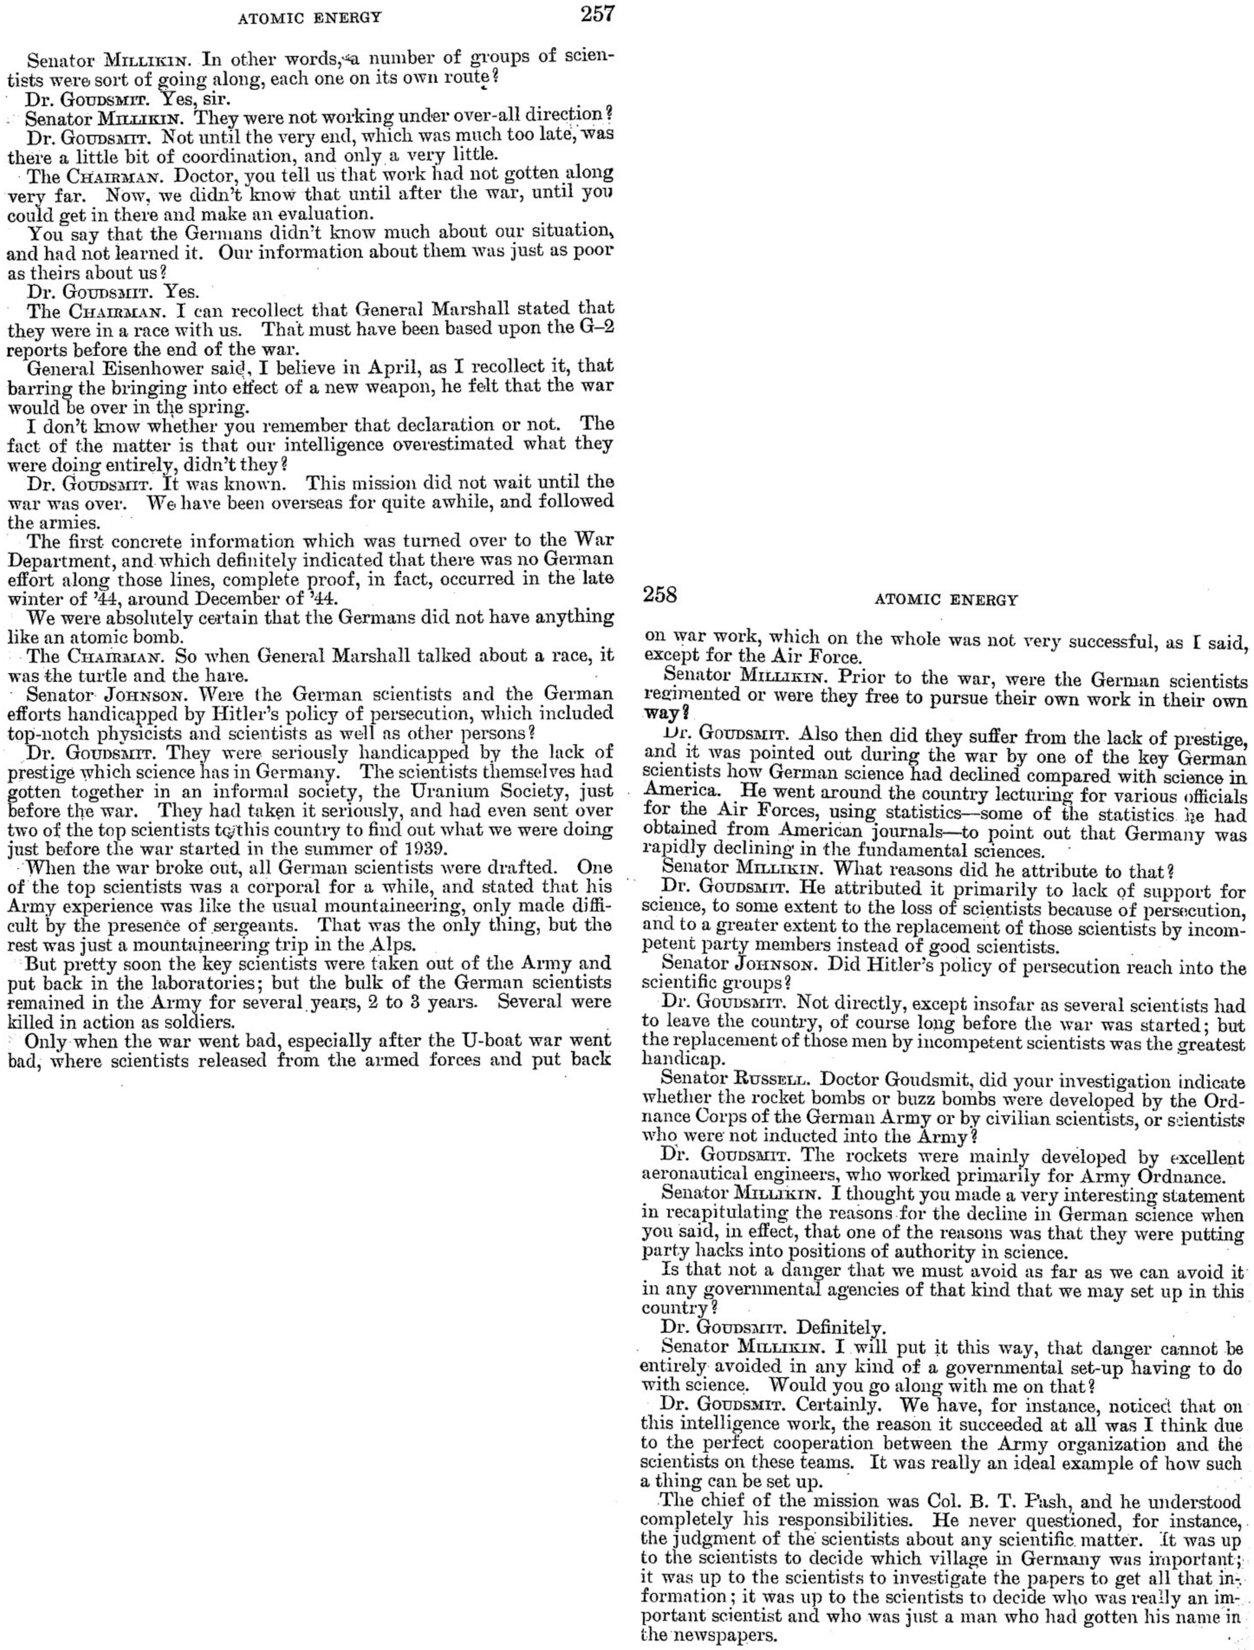
Senator MILLIKIN. Then did any group or any top coordinating agency pull this altogether into some sort of definitive statement?

Dr. GOUDSMIT. No.

Senator MILLIKIN. That was not done?

Dr. GOUDSMIT. No; it was simply done in the form of secret publications.

Figure D.27: Samuel Goudsmit's 6 December 1945 testimony to the U.S. Senate [Goudsmit 1945].



Senator MILLIKIN. In other words, a number of groups of scientists were sort of going along, each one on its own route?

Dr. GOUDSMIT. Yes, sir.

Senator MILLIKIN. They were not working under over-all direction?

Dr. GOUDSMIT. Not until the very end, which was much too late, was there a little bit of coordination, and only a very little.

The CHAIRMAN. Doctor, you tell us that work had not gotten along very far. Now, we didn't know that until after the war, until you could get in there and make an evaluation.

You say that the Germans didn't know much about our situation, and had not learned it. Our information about them was just as poor as theirs about us?

Dr. GOUDSMIT. Yes.

The CHAIRMAN. I can recollect that General Marshall stated that they were in a race with us. That must have been based upon the G–2 reports before the end of the war.

General Eisenhower said, I believe in April, as I recollect it, that barring the bringing into effect of a new weapon, he felt that the war would be over in the spring.

I don't know whether you remember that declaration or not. The fact of the matter is that our intelligence overestimated what they were doing entirely, didn't they?

Dr. GOUDSMIT. It was known. This mission did not wait until the war was over. We have been overseas for quite awhile, and followed the armies.

The first concrete information which was turned over to the War Department, and which definitely indicated that there was no German effort along those lines, complete proof, in fact, occurred in the late winter of '44, around December of '44.

We were absolutely certain that the Germans did not have anything like an atomic bomb.

The CHAIRMAN. So when General Marshall talked about a race, it was the turtle and the hare.

Senator JOHNSON. Were the German scientists and the German efforts handicapped by Hitler's policy of persecution, which included top-notch physicists and scientists as well as other persons?

Dr. GOUDSMIT. They were seriously handicapped by the lack of prestige which science has in Germany. The scientists themselves had gotten together in an informal society, the Uranium Society, just before the war. They had taken it seriously, and had even sent over two of the top scientists to this country to find out what we were doing just before the war started in the summer of 1939.

When the war broke out, all German scientists were drafted. One of the top scientists was a corporal for a while, and stated that his Army experience was like the usual mountaineering, only made difficult by the presence of sergeants. That was the only thing, but the rest was just a mountaineering trip in the Alps.

But pretty soon the key scientists were taken out of the Army and put back in the laboratories; but the bulk of the German scientists remained in the Army for several years, 2 to 3 years. Several were killed in action as soldiers.

Only when the war went bad, especially after the U-boat war went bad, where scientists released from the armed forces and put back

on war work, which on the whole was not very successful, as I said, except for the Air Force.

Senator MILLIKIN. Prior to the war, were the German scientists regimented or were they free to pursue their own work in their own way?

Dr. GOUDSMIT. Also then did they suffer from the lack of prestige, and it was pointed out during the war by one of the key German scientists how German science had declined compared with science in America. He went around the country lecturing for various officials for the Air Forces, using statistics—some of the statistics he had obtained from American journals—to point out that Germany was rapidly declining in the fundamental sciences.

Senator MILLIKIN. What reasons did he attribute to that?

Dr. GOUDSMIT. He attributed it primarily to lack of support for science, to some extent to the loss of scientists because of persecution, and to a greater extent to the replacement of those scientists by incompetent party members instead of good scientists.

Senator JOHNSON. Did Hitler's policy of persecution reach into the scientific groups?

Dr. GOUDSMIT. Not directly, except insofar as several scientists had to leave the country, of course long before the war was started; but the replacement of those men by incompetent scientists was the greatest handicap.

Senator RUSSELL. Doctor Goudsmit, did your investigation indicate whether the rocket bombs or buzz bombs were developed by the Ordnance Corps of the German Army or by civilian scientists, or scientists who were not inducted into the Army?

Dr. GOUDSMIT. The rockets were mainly developed by excellent aeronautical engineers, who worked primarily for Army Ordnance.

Senator MILLIKIN. I thought you made a very interesting statement in recapitulating the reasons for the decline in German science when you said, in effect, that one of the reasons was that they were putting party hacks into positions of authority in science.

Is that not a danger that we must avoid as far as we can avoid it in any governmental agencies of that kind that we may set up in this country?

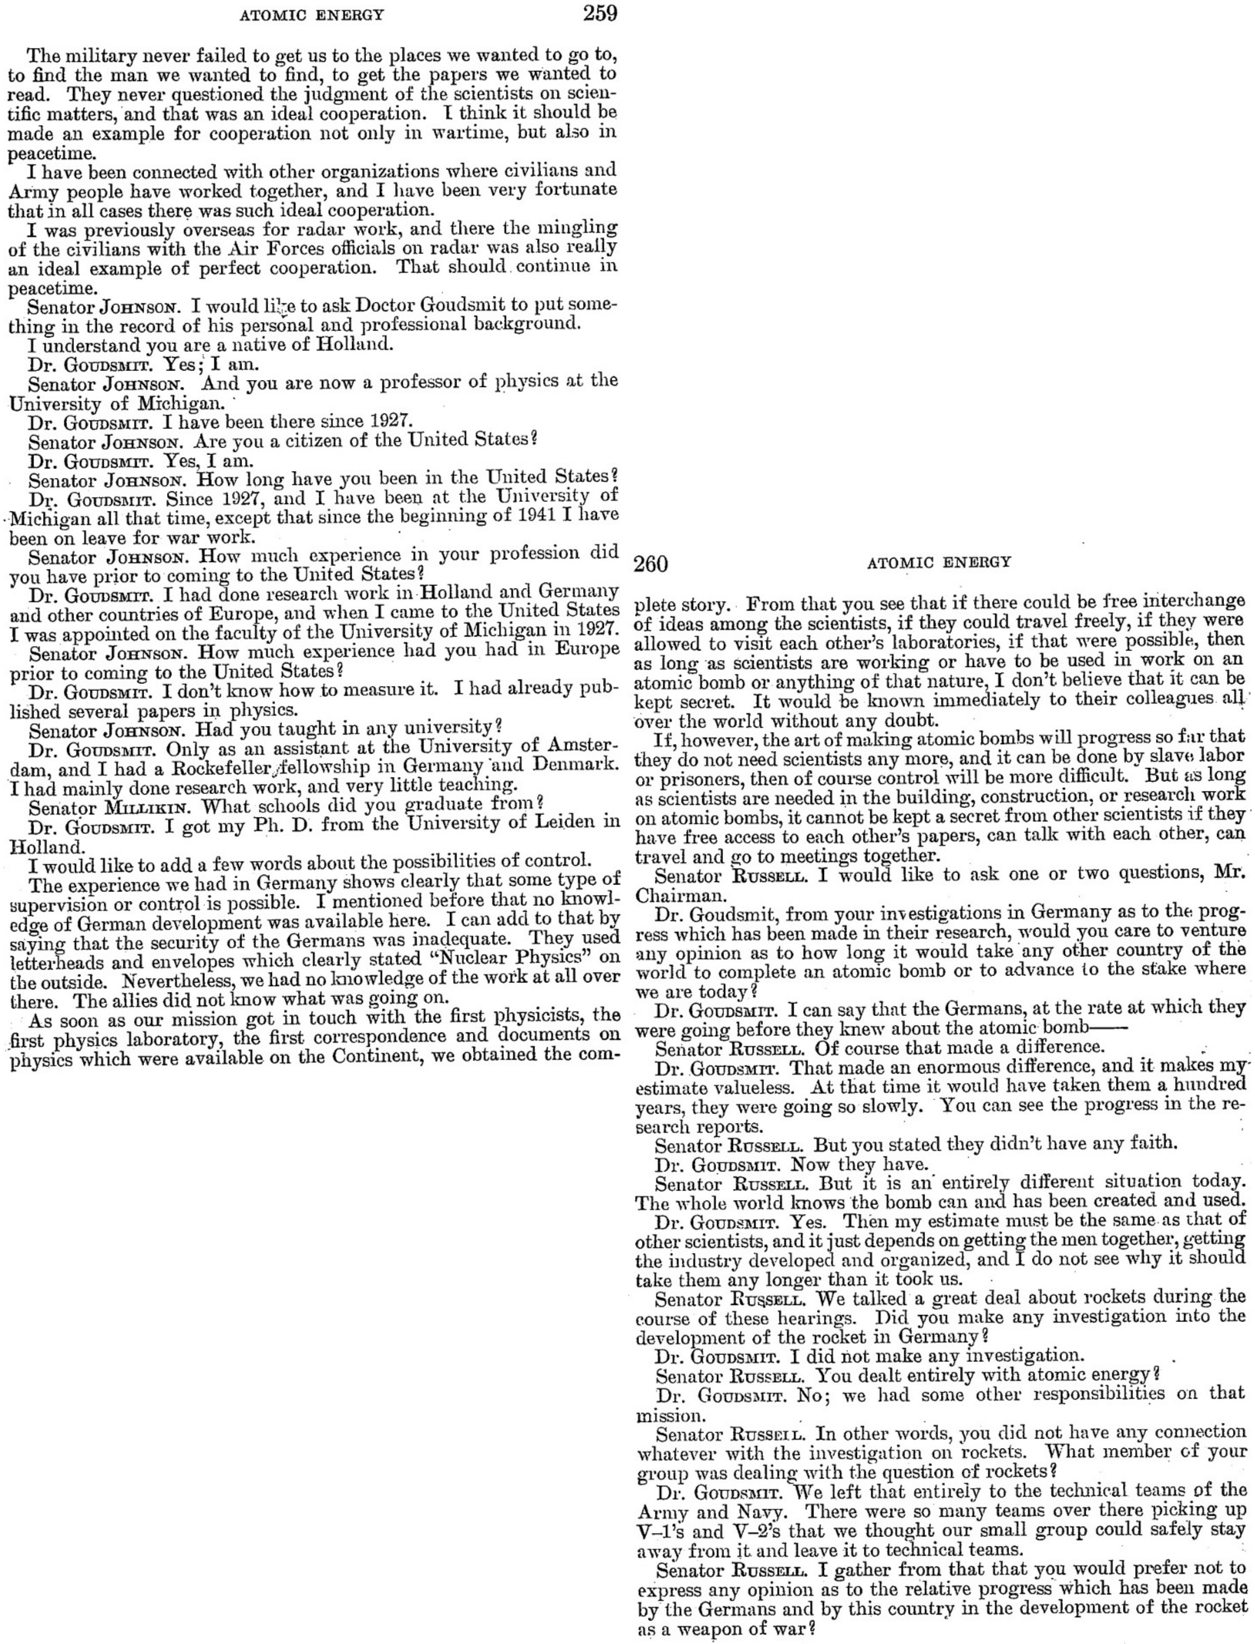
Dr. GOUDSMIT. Definitely.

Senator MILLIKIN. I will put it this way, that danger cannot be entirely avoided in any kind of a governmental set-up having to do with science. Would you go along with me on that?

Dr. GOUDSMIT. Certainly. We have, for instance, noticed that on this intelligence work, the reason it succeeded at all was I think due to the perfect cooperation between the Army organization and the scientists on these teams. It was really an ideal example of how such a thing can be set up.

The chief of the mission was Col. B. T. Pash, and he understood completely his responsibilities. He never questioned, for instance, the judgment of the scientists about any scientific matter. It was up to the scientists to decide which village in Germany was important; it was up to the scientists to investigate the papers to get all that information; it was up to the scientists to decide who was really an important scientist and who was just a man who had gotten his name in the newspapers.

Figure D.28: Samuel Goudsmit's 6 December 1945 testimony to the U.S. Senate [Goudsmit 1945].



ATOMIC ENERGY 259

The military never failed to get us to the places we wanted to go to, to find the man we wanted to find, to get the papers we wanted to read. They never questioned the judgment of the scientists on scientific matters, and that was an ideal cooperation. I think it should be made an example for cooperation not only in wartime, but also in peacetime.

I have been connected with other organizations where civilians and Army people have worked together, and I have been very fortunate that in all cases there was such ideal cooperation.

I was previously overseas for radar work, and there the mingling of the civilians with the Air Forces officials on radar was also really an ideal example of perfect cooperation. That should continue in peacetime.

Senator JOHNSON. I would like to ask Doctor Goudsmit to put something in the record of his personal and professional background.

I understand you are a native of Holland.

Dr. GOUDSMIT. Yes; I am.

Senator JOHNSON. And you are now a professor of physics at the University of Michigan.

Dr. GOUDSMIT. I have been there since 1927.

Senator JOHNSON. Are you a citizen of the United States?

Dr. GOUDSMIT. Yes, I am.

Senator JOHNSON. How long have you been in the United States?

Dr. GOUDSMIT. Since 1927, and I have been at the University of Michigan all that time, except that since the beginning of 1941 I have been on leave for war work.

Senator JOHNSON. How much experience in your profession did you have prior to coming to the United States?

Dr. GOUDSMIT. I had done research work in Holland and Germany and other countries of Europe, and when I came to the United States I was appointed on the faculty of the University of Michigan in 1927.

Senator JOHNSON. How much experience had you had in Europe prior to coming to the United States?

Dr. GOUDSMIT. I don't know how to measure it. I had already published several papers in physics.

Senator JOHNSON. Had you taught in any university?

Dr. GOUDSMIT. Only as an assistant at the University of Amsterdam, and I had a Rockefeller fellowship in Germany and Denmark. I had mainly done research work, and very little teaching.

Senator MILLIKIN. What schools did you graduate from?

Dr. GOUDSMIT. I got my Ph. D. from the University of Leiden in Holland.

I would like to add a few words about the possibilities of control.

The experience we had in Germany shows clearly that some type of supervision or control is possible. I mentioned before that no knowledge of German development was available here. I can add to that by saying that the security of the Germans was inadequate. They used letterheads and envelopes which clearly stated "Nuclear Physics" on the outside. Nevertheless, we had no knowledge of the work at all over there. The allies did not know what was going on.

As soon as our mission got in touch with the first physicists, the first physics laboratory, the first correspondence and documents on physics which were available on the Continent, we obtained the complete story. From that you see that if there could be free interchange of ideas among the scientists, if they could travel freely, if they were allowed to visit each other's laboratories, if that were possible, then as long as scientists are working or have to be used in work on an atomic bomb or anything of that nature, I don't believe that it can be kept secret. It would be known immediately to their colleagues all over the world without any doubt.

260 ATOMIC ENERGY

If, however, the art of making atomic bombs will progress so far that they do not need scientists any more, and it can be done by slave labor or prisoners, then of course control will be more difficult. But as long as scientists are needed in the building, construction, or research work on atomic bombs, it cannot be kept a secret from other scientists if they have free access to each other's papers, can talk with each other, can travel and go to meetings together.

Senator RUSSELL. I would like to ask one or two questions, Mr. Chairman.

Dr. Goudsmit, from your investigations in Germany as to the progress which has been made in their research, would you care to venture any opinion as to how long it would take any other country of the world to complete an atomic bomb or to advance to the stake where we are today?

Dr. GOUDSMIT. I can say that the Germans, at the rate at which they were going before they knew about the atomic bomb——

Senator RUSSELL. Of course that made a difference.

Dr. GOUDSMIT. That made an enormous difference, and it makes my estimate valueless. At that time it would have taken them a hundred years, they were going so slowly. You can see the progress in the research reports.

Senator RUSSELL. But you stated they didn't have any faith.

Dr. GOUDSMIT. Now they have.

Senator RUSSELL. But it is an entirely different situation today. The whole world knows the bomb can and has been created and used.

Dr. GOUDSMIT. Yes. Then my estimate must be the same as that of other scientists, and it just depends on getting the men together, getting the industry developed and organized, and I do not see why it should take them any longer than it took us.

Senator RUSSELL. We talked a great deal about rockets during the course of these hearings. Did you make any investigation into the development of the rocket in Germany?

Dr. GOUDSMIT. I did not make any investigation.

Senator RUSSELL. You dealt entirely with atomic energy?

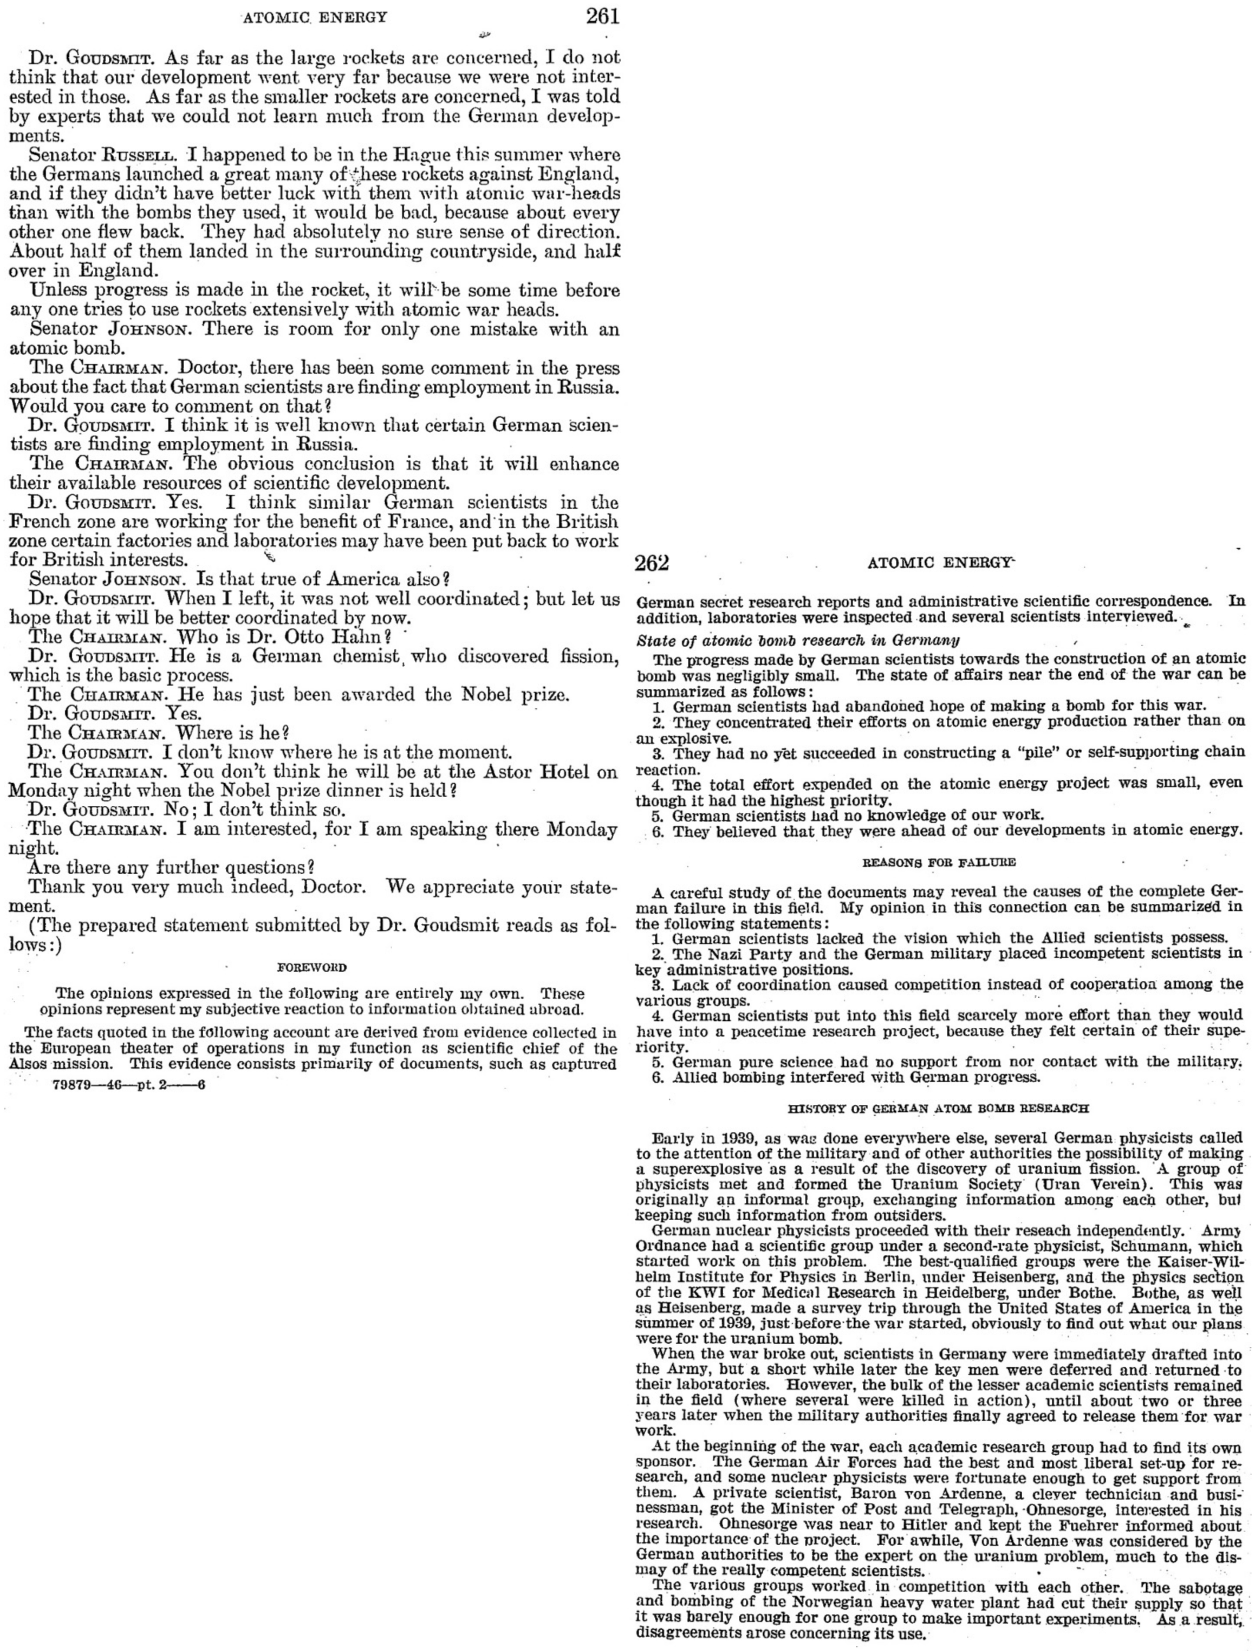
Dr. GOUDSMIT. No; we had some other responsibilities on that mission.

Senator RUSSELL. In other words, you did not have any connection whatever with the investigation on rockets. What member of your group was dealing with the question of rockets?

Dr. GOUDSMIT. We left that entirely to the technical teams of the Army and Navy. There were so many teams over there picking up V–1's and V–2's that we thought our small group could safely stay away from it and leave it to technical teams.

Senator RUSSELL. I gather from that that you would prefer not to express any opinion as to the relative progress which has been made by the Germans and by this country in the development of the rocket as a weapon of war?

Figure D.29: Samuel Goudsmit's 6 December 1945 testimony to the U.S. Senate [Goudsmit 1945].



ATOMIC ENERGY 261

Dr. Goudsmit. As far as the large rockets are concerned, I do not think that our development went very far because we were not interested in those. As far as the smaller rockets are concerned, I was told by experts that we could not learn much from the German developments.

Senator Russell. I happened to be in the Hague this summer where the Germans launched a great many of these rockets against England, and if they didn't have better luck with them with atomic war-heads than with the bombs they used, it would be bad, because about every other one flew back. They had absolutely no sure sense of direction. About half of them landed in the surrounding countryside, and half over in England.

Unless progress is made in the rocket, it will be some time before any one tries to use rockets extensively with atomic war heads.

Senator Johnson. There is room for only one mistake with an atomic bomb.

The Chairman. Doctor, there has been some comment in the press about the fact that German scientists are finding employment in Russia. Would you care to comment on that?

Dr. Goudsmit. I think it is well known that certain German scientists are finding employment in Russia.

The Chairman. The obvious conclusion is that it will enhance their available resources of scientific development.

Dr. Goudsmit. Yes. I think similar German scientists in the French zone are working for the benefit of France, and in the British zone certain factories and laboratories may have been put back to work for British interests.

Senator Johnson. Is that true of America also?

Dr. Goudsmit. When I left, it was not well coordinated; but let us hope that it will be better coordinated by now.

The Chairman. Who is Dr. Otto Hahn?

Dr. Goudsmit. He is a German chemist who discovered fission, which is the basic process.

The Chairman. He has just been awarded the Nobel prize.

Dr. Goudsmit. Yes.

The Chairman. Where is he?

Dr. Goudsmit. I don't know where he is at the moment.

The Chairman. You don't think he will be at the Astor Hotel on Monday night when the Nobel prize dinner is held?

Dr. Goudsmit. No; I don't think so.

The Chairman. I am interested, for I am speaking there Monday night.

Are there any further questions?

Thank you very much indeed, Doctor. We appreciate your statement.

(The prepared statement submitted by Dr. Goudsmit reads as follows:)

FOREWORD

The opinions expressed in the following are entirely my own. These opinions represent my subjective reaction to information obtained abroad.

The facts quoted in the following account are derived from evidence collected in the European theater of operations in my function as scientific chief of the Alsos mission. This evidence consists primarily of documents, such as captured German secret research reports and administrative scientific correspondence. In addition, laboratories were inspected and several scientists interviewed.

79879—46—pt. 2——6

262 ATOMIC ENERGY

State of atomic bomb research in Germany

The progress made by German scientists towards the construction of an atomic bomb was negligibly small. The state of affairs near the end of the war can be summarized as follows:

1. German scientists had abandoned hope of making a bomb for this war.
2. They concentrated their efforts on atomic energy production rather than on an explosive.
3. They had no yet succeeded in constructing a "pile" or self-supporting chain reaction.
4. The total effort expended on the atomic energy project was small, even though it had the highest priority.
5. German scientists had no knowledge of our work.
6. They believed that they were ahead of our developments in atomic energy.

REASONS FOR FAILURE

A careful study of the documents may reveal the causes of the complete German failure in this field. My opinion in this connection can be summarized in the following statements:

1. German scientists lacked the vision which the Allied scientists possess.
2. The Nazi Party and the German military placed incompetent scientists in key administrative positions.
3. Lack of coordination caused competition instead of cooperation among the various groups.
4. German scientists put into this field scarcely more effort than they would have into a peacetime research project, because they felt certain of their superiority.
5. German pure science had no support from nor contact with the military.
6. Allied bombing interfered with German progress.

HISTORY OF GERMAN ATOM BOMB RESEARCH

Early in 1939, as was done everywhere else, several German physicists called to the attention of the military and of other authorities the possibility of making a superexplosive as a result of the discovery of uranium fission. A group of physicists met and formed the Uranium Society (Uran Verein). This was originally an informal group, exchanging information among each other, but keeping such information from outsiders.

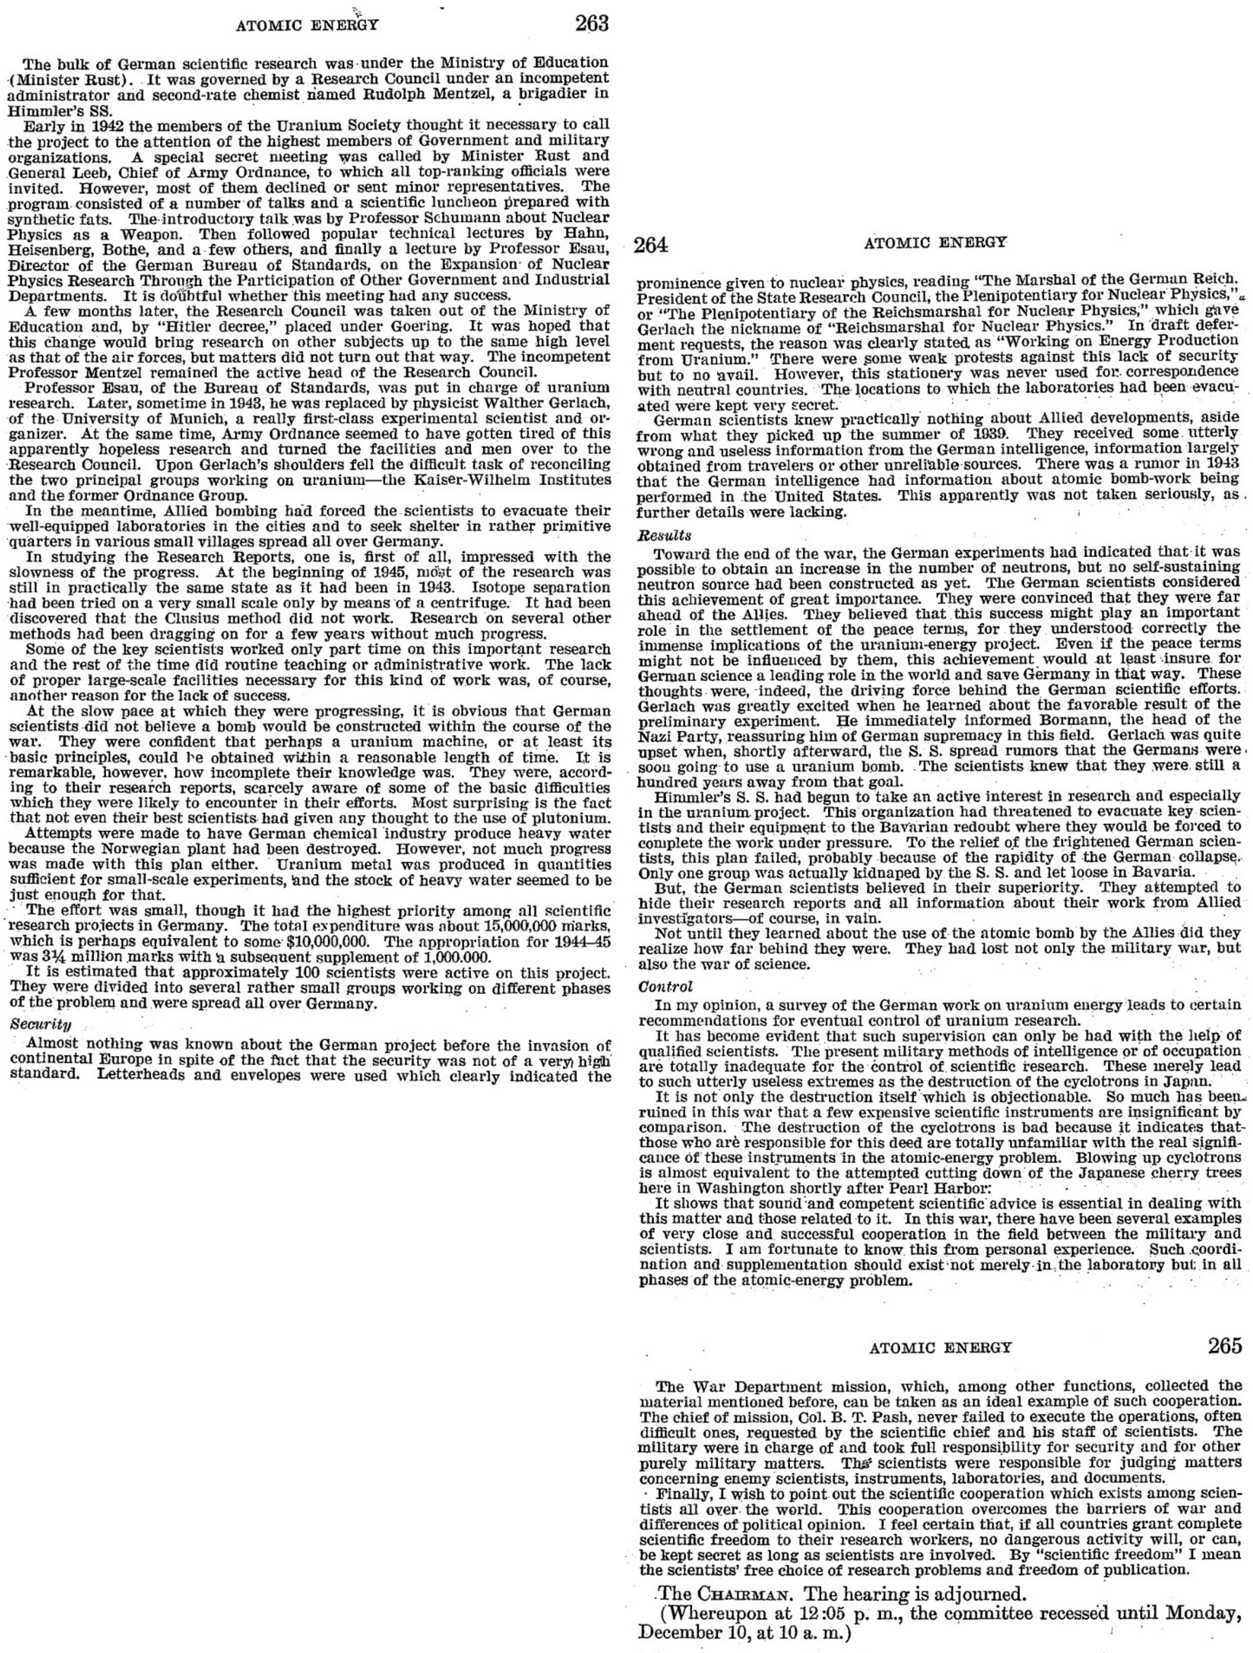
German nuclear physicists proceeded with their reseach independently. Army Ordnance had a scientific group under a second-rate physicist, Schumann, which started work on this problem. The best-qualified groups were the Kaiser-Wilhelm Institute for Physics in Berlin, under Heisenberg, and the physics section of the KWI for Medical Research in Heidelberg, under Bothe. Bothe, as well as Heisenberg, made a survey trip through the United States of America in the summer of 1939, just before the war started, obviously to find out what our plans were for the uranium bomb.

When the war broke out, scientists in Germany were immediately drafted into the Army, but a short while later the key men were deferred and returned to their laboratories. However, the bulk of the lesser academic scientists remained in the field (where several were killed in action), until about two or three years later when the military authorities finally agreed to release them for war work.

At the beginning of the war, each academic research group had to find its own sponsor. The German Air Forces had the best and most liberal set-up for research, and some nuclear physicists were fortunate enough to get support from them. A private scientist, Baron von Ardenne, a clever technician and businessman, got the Minister of Post and Telegraph, Ohnesorge, interested in his research. Ohnesorge was near to Hitler and kept the Fuehrer informed about the importance of the project. For awhile, Von Ardenne was considered by the German authorities to be the expert on the uranium problem, much to the dismay of the really competent scientists.

The various groups worked in competition with each other. The sabotage and bombing of the Norwegian heavy water plant had cut their supply so that it was barely enough for one group to make important experiments. As a result, disagreements arose concerning its use.

Figure D.30: Samuel Goudsmit's 6 December 1945 testimony to the U.S. Senate [Goudsmit 1945].



The bulk of German scientific research was under the Ministry of Education (Minister Rust). It was governed by a Research Council under an incompetent administrator and second-rate chemist named Rudolph Mentzel, a brigadier in Himmler's SS.

Early in 1942 the members of the Uranium Society thought it necessary to call the project to the attention of the highest members of Government and military organizations. A special secret meeting was called by Minister Rust and General Leeb, Chief of Army Ordnance, to which all top-ranking officials were invited. However, most of them declined or sent minor representatives. The program consisted of a number of talks and a scientific luncheon prepared with synthetic fats. The introductory talk was by Professor Schumann about Nuclear Physics as a Weapon. Then followed popular technical lectures by Hahn, Heisenberg, Bothe, and a few others, and finally a lecture by Professor Esau, Director of the German Bureau of Standards, on the Expansion of Nuclear Physics Research Through the Participation of Other Government and Industrial Departments. It is doubtful whether this meeting had any success.

A few months later, the Research Council was taken out of the Ministry of Education and, by "Hitler decree," placed under Goering. It was hoped that this change would bring research on other subjects up to the same high level as that of the air forces, but matters did not turn out that way. The incompetent Professor Mentzel remained the active head of the Research Council.

Professor Esau, of the Bureau of Standards, was put in charge of uranium research. Later, sometime in 1943, he was replaced by physicist Walther Gerlach, of the University of Munich, a really first-class experimental scientist and organizer. At the same time, Army Ordnance seemed to have gotten tired of this apparently hopeless research and turned the facilities and men over to the Research Council. Upon Gerlach's shoulders fell the difficult task of reconciling the two principal groups working on uranium—the Kaiser-Wilhelm Institutes and the former Ordnance Group.

In the meantime, Allied bombing had forced the scientists to evacuate their well-equipped laboratories in the cities and to seek shelter in rather primitive quarters in various small villages spread all over Germany.

In studying the Research Reports, one is, first of all, impressed with the slowness of the progress. At the beginning of 1945, most of the research was still in practically the same state as it had been in 1943. Isotope separation had been tried on a very small scale only by means of a centrifuge. It had been discovered that the Clusius method did not work. Research on several other methods had been dragging on for a few years without much progress.

Some of the key scientists worked only part time on this important research and the rest of the time did routine teaching or administrative work. The lack of proper large-scale facilities necessary for this kind of work was, of course, another reason for the lack of success.

At the slow pace at which they were progressing, it is obvious that German scientists did not believe a bomb would be constructed within the course of the war. They were confident that perhaps a uranium machine, or at least its basic principles, could be obtained within a reasonable length of time. It is remarkable, however, how incomplete their knowledge was. They were, according to their research reports, scarcely aware of some of the basic difficulties which they were likely to encounter in their efforts. Most surprising is the fact that not even their best scientists had given any thought to the use of plutonium.

Attempts were made to have German chemical industry produce heavy water because the Norwegian plant had been destroyed. However, not much progress was made with this plan either. Uranium metal was produced in quantities sufficient for small-scale experiments, and the stock of heavy water seemed to be just enough for that.

The effort was small, though it had the highest priority among all scientific research projects in Germany. The total expenditure was about 15,000,000 marks, which is perhaps equivalent to some $10,000,000. The appropriation for 1944–45 was 3¼ million marks with a subsequent supplement of 1,000,000.

It is estimated that approximately 100 scientists were active on this project. They were divided into several rather small groups working on different phases of the problem and were spread all over Germany.

Security

Almost nothing was known about the German project before the invasion of continental Europe in spite of the fact that the security was not of a very high standard. Letterheads and envelopes were used which clearly indicated the

prominence given to nuclear physics, reading "The Marshal of the German Reich, President of the State Research Council, the Plenipotentiary for Nuclear Physics," or "The Plenipotentiary of the Reichsmarshal for Nuclear Physics," which gave Gerlach the nickname of "Reichsmarshal for Nuclear Physics." In draft deferment requests, the reason was clearly stated as "Working on Energy Production from Uranium." There were some weak protests against this lack of security but to no avail. However, this stationery was never used for correspondence with neutral countries. The locations to which the laboratories had been evacuated were kept very secret.

German scientists knew practically nothing about Allied developments, aside from what they picked up the summer of 1939. They received some utterly wrong and useless information from the German intelligence, information largely obtained from travelers or other unreliable sources. There was a rumor in 1943 that the German intelligence had information about atomic bomb-work being performed in the United States. This apparently was not taken seriously, as further details were lacking.

Results

Toward the end of the war, the German experiments had indicated that it was possible to obtain an increase in the number of neutrons, but no self-sustaining neutron source had been constructed as yet. The German scientists considered this achievement of great importance. They were convinced that they were far ahead of the Allies. They believed that this success might play an important role in the settlement of the peace terms, for they understood correctly the immense implications of the uranium-energy project. Even if the peace terms might not be influenced by them, this achievement would at least insure for German science a leading role in the world and save Germany in that way. These thoughts were, indeed, the driving force behind the German scientific efforts. Gerlach was greatly excited when he learned about the favorable result of the preliminary experiment. He immediately informed Bormann, the head of the Nazi Party, reassuring him of German supremacy in this field. Gerlach was quite upset when, shortly afterward, the S. S. spread rumors that the Germans were soon going to use a uranium bomb. The scientists knew that they were still a hundred years away from that goal.

Himmler's S. S. had begun to take an active interest in research and especially in the uranium project. This organization had threatened to evacuate key scientists and their equipment to the Bavarian redoubt where they would be forced to complete the work under pressure. To the relief of the frightened German scientists, this plan failed, probably because of the rapidity of the German collapse. Only one group was actually kidnaped by the S. S. and let loose in Bavaria.

But, the German scientists believed in their superiority. They attempted to hide their research reports and all information about their work from Allied investigators—of course, in vain.

Not until they learned about the use of the atomic bomb by the Allies did they realize how far behind they were. They had lost not only the military war, but also the war of science.

Control

In my opinion, a survey of the German work on uranium energy leads to certain recommendations for eventual control of uranium research.

It has become evident that such supervision can only be had with the help of qualified scientists. The present military methods of intelligence or of occupation are totally inadequate for the control of scientific research. These merely lead to such utterly useless extremes as the destruction of the cyclotrons in Japan.

It is not only the destruction itself which is objectionable. So much has been ruined in this war that a few expensive scientific instruments are insignificant by comparison. The destruction of the cyclotrons is bad because it indicates that those who are responsible for this deed are totally unfamiliar with the real significance of these instruments in the atomic-energy problem. Blowing up cyclotrons is almost equivalent to the attempted cutting down of the Japanese cherry trees here in Washington shortly after Pearl Harbor.

It shows that sound and competent scientific advice is essential in dealing with this matter and those related to it. In this war, there have been several examples of very close and successful cooperation in the field between the military and scientists. I am fortunate to know this from personal experience. Such coordination and supplementation should exist not merely in the laboratory but in all phases of the atomic-energy problem.

The War Department mission, which, among other functions, collected the material mentioned before, can be taken as an ideal example of such cooperation. The chief of mission, Col. B. T. Pash, never failed to execute the operations, often difficult ones, requested by the scientific chief and his staff of scientists. The military were in charge of and took full responsibility for security and for other purely military matters. The scientists were responsible for judging matters concerning enemy scientists, instruments, laboratories, and documents.

Finally, I wish to point out the scientific cooperation which exists among scientists all over the world. This cooperation overcomes the barriers of war and differences of political opinion. I feel certain that, if all countries grant complete scientific freedom to their research workers, no dangerous activity will, or can, be kept secret as long as scientists are involved. By "scientific freedom" I mean the scientists' free choice of research problems and freedom of publication.

The CHAIRMAN. The hearing is adjourned.

(Whereupon at 12:05 p. m., the committee recessed until Monday, December 10, at 10 a. m.)

Figure D.31: Samuel Goudsmit's 6 December 1945 testimony to the U.S. Senate [Goudsmit 1945].

Samuel A. Goudsmit. 7 December 1945. Report by the Scientific Chief of the Alsos Mission, pp. 15–16 [NARA RG GOUDS, Entry UD-7420, Box 6, Folder Alsos Mission].

Limitations of Fields of Interest

Experience has shown that it was impossible to cover efficiently the whole field of scientific research in Germany. The amount of material, such as documents, personnel and laboratories, encountered during operations was so overwhelming that no intelligence agency of reasonable size could handle it all. A very thorough job could be done, however, on such scientific subjects for which there existed at home or in the field a definite demand for intelligence information. For this reason, the Alsos Mission, more or less automatically, restricted its investigations to the following subjects:

a. The Uranium Problem

b. Bacteriological Warfare

c. Organization of Enemy Scientific Research

d. Aeronautical Research

e. Proximity Fuzes

f. German Research Facilities for Guided Missiles

g. The Speer Ministry's Interest in Research

h. Chemical Research

i. Metallurgical Research

j. Shale Oil Development

k. Miscellaneous Intelligence [...]

Scientific Results Obtained by the Alsos Mission

a. The Uranium Project.

The Alsos Mission was the only intelligence team authorized to investigate for United States and British interests the German progress on the Atom Bomb. Documents found at Strasbourg indicated that the enemy had made practically no progress in this field, though it had the highest priority of all scientific research projects. The Alsos Mission located all the centers of Uranium research in Germany. The laboratories were investigated and key personnel detained and questioned. The enemy tried in vain to hide essential materials and research reports. They were all recovered by the Alsos Mission. It is certain that complete research data and all key scientists fell into the hands of the Alsos Mission.

The evaluation of the intelligence indicated that the Germans believed that they were far ahead of American development in this field. In reality, the Germans, though they had started sooner, were far behind. They had given up altogether the idea of making a bomb and were concentrating their efforts on constructing an energy producing machine, which they called a "Uranium Burner". At the end of the war, they had not even succeeded in constructing a self-sustaining chain reaction or "pile". Nevertheless, they believed their progress to be so important that they offered to assist United States scientists in their efforts to harness atomic energy. They were convinced that their work would help Germany to dominate the world of science even though the military struggle had been lost. Not until the news of the Atomic Bomb reached them on August 7, 1945, did German scientists realize that they had also lost the war of physics. [...]

Conclusion

It is the opinion of the Scientific Chief that the Mission has been highly successful. It has taught us lessons in intelligence procedure which may be of great value in peacetime, too. This fact is of greater importance than the actual scientific information which was collected, the bulk of which was negative.

Only the method used by the Alsos Mission could have revealed, immediately after the fall of Strasbourg, that no threat of a German Atom Bomb existed. From a military point of view, this was the most important result obtained by the Mission.

The Alsos method, it must be emphasized, succeeded only because of the close cooperation and mutual trust of the military and the scientists. For all members, this Mission has been a unique undertaking, giving the inner satisfaction of having actively contributed to the success of the Allied cause.

[Samuel Goudsmit's final report for the Alsos mission was 25 pages long, yet devoted only approximately one page to the German nuclear program, giving little detail. Goudsmit spent far more pages of the report on extreme self-promotion and a long series of petty complaints, such as that the U.S. government had declined his requests to give him his own private plane.

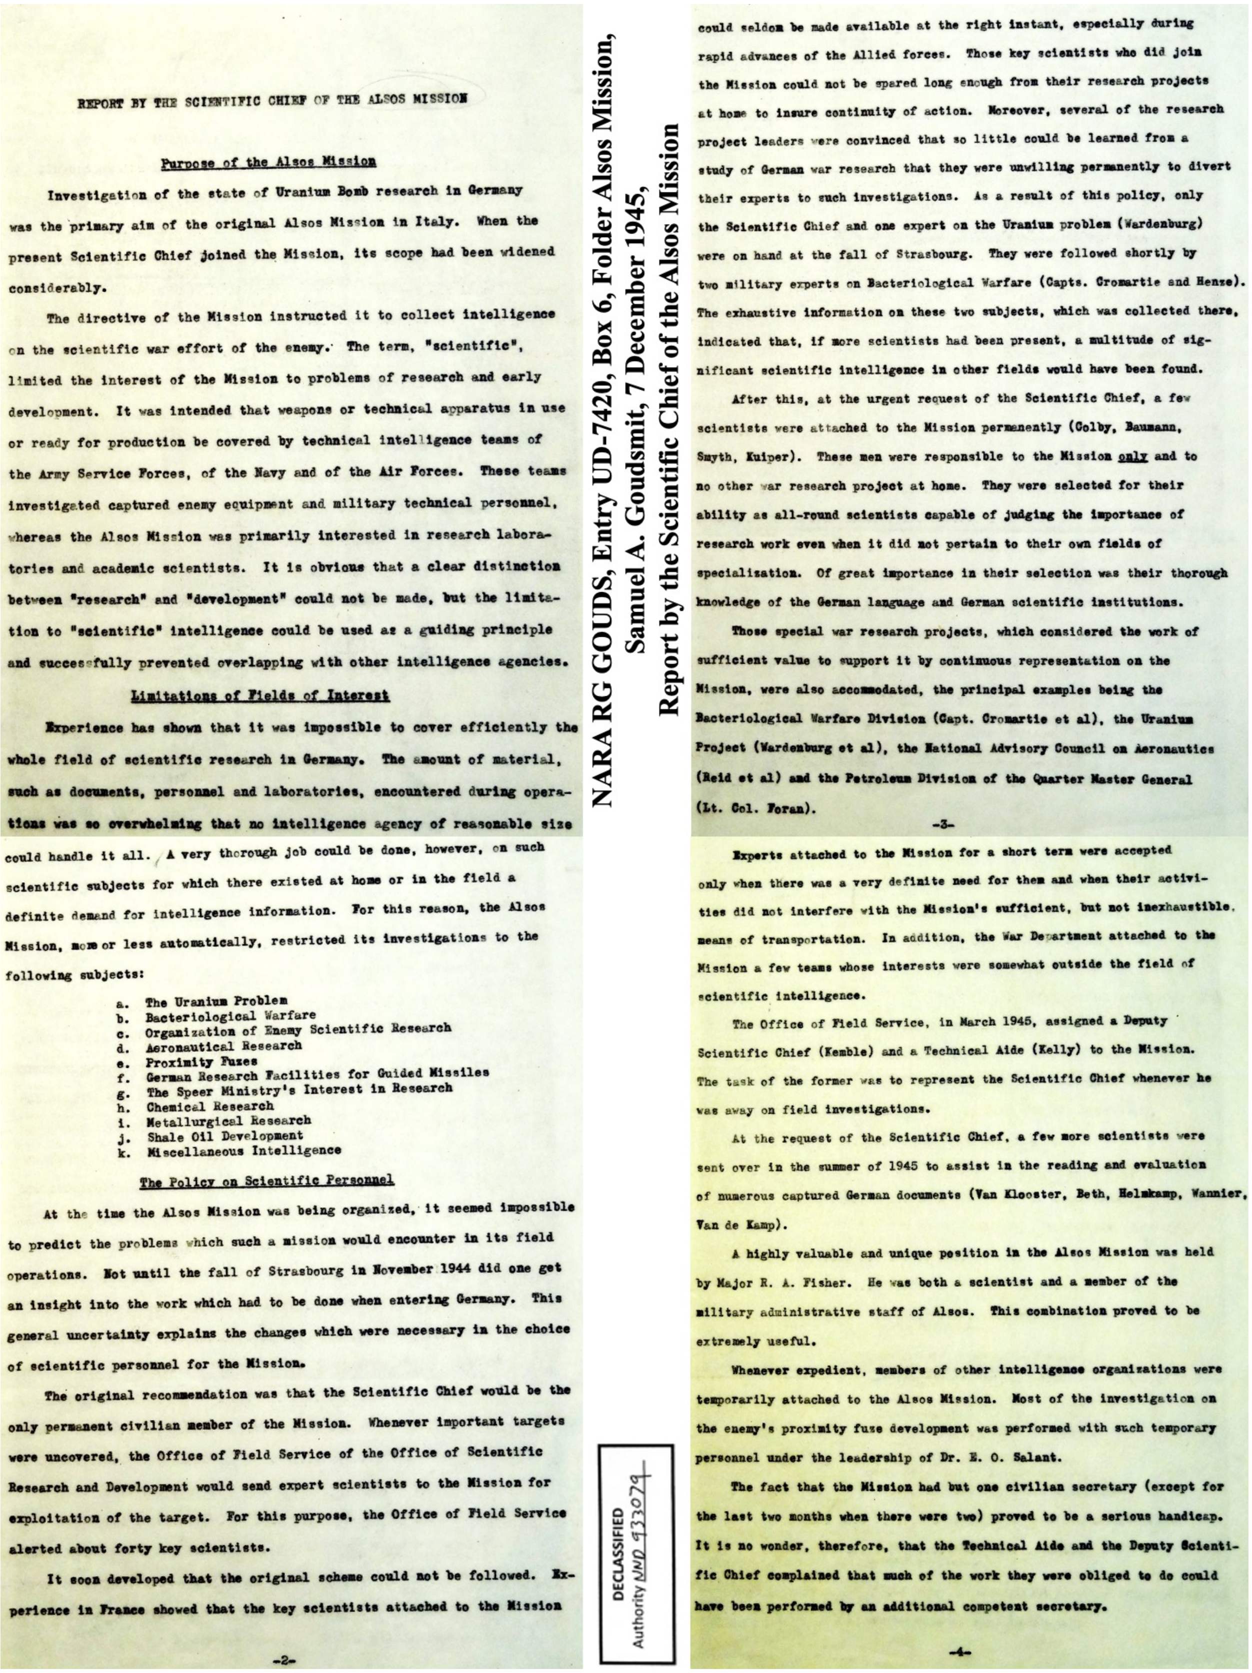
Goudsmit was especially proud of his own unique method that "revealed... no threat of a German Atom Bomb existed" before he had ever even visited any sites in Germany or its eastern occupied territories, read any documents from those sites, seen any equipment from those sites, or interrogated any personnel from those sites. Undoubtedly that was indeed a unique method.

Alsos's own files prove that Goudsmit was knowingly making false statements when he wrote claims such as: "The Alsos Mission located all the centers of Uranium research in Germany. The laboratories were investigated... It is certain that complete research data and all key scientists fell into the hands of the Alsos Mission." (See for example pp. 3271–3273, 3279–3283, 3285–3287, 3294–3296, 3288–3289, 3292–3293.)

Note the long list of German fields of research (each quite vast, as shown by other sections of this book) for which Goudsmit, with only a small number of assistants for a few months, claims to have done "a very thorough job."

In stark contrast to Goudsmit's glowing evaluation of himself, the archival record shows that he:

- Had a nervous breakdown long before Allied forces even entered Germany and spent most of the final months of the war in the United States (e.g., pp. 3260–3269).
- Quarreled with and was criticized by a long list of people (e.g., pp. 3260–3261, 3264–3265, 3266–3269, 3274–3275, 3278, 3285–3287, 3288–3289, 3292–3293, 3294–3296, 3321).
- Failed to investigate a huge number of nuclear sites and personnel (e.g., pp. 3279–3283).
- Was ultimately judged to have failed in his mission by SHAEF G-2 Generals Thomas J. Betts and George Bryan Conrad plus AAF General Henry Arnold's advisor Prof. Edward L. Bowles of MIT (pp. 3285–3287).
- Knowingly and repeatedly gave false testimony to the United States Senate (pp. 3297–3305).]



REPORT BY THE SCIENTIFIC CHIEF OF THE ALSOS MISSION

Purpose of the Alsos Mission

Investigation of the state of Uranium Bomb research in Germany was the primary aim of the original Alsos Mission in Italy. When the present Scientific Chief joined the Mission, its scope had been widened considerably.

The directive of the Mission instructed it to collect intelligence on the scientific war effort of the enemy. The term, "scientific", limited the interest of the Mission to problems of research and early development. It was intended that weapons or technical apparatus in use or ready for production be covered by technical intelligence teams of the Army Service Forces, of the Navy and of the Air Forces. These teams investigated captured enemy equipment and military technical personnel, whereas the Alsos Mission was primarily interested in research laboratories and academic scientists. It is obvious that a clear distinction between "research" and "development" could not be made, but the limitation to "scientific" intelligence could be used as a guiding principle and successfully prevented overlapping with other intelligence agencies.

Limitations of Fields of Interest

Experience has shown that it was impossible to cover efficiently the whole field of scientific research in Germany. The amount of material, such as documents, personnel and laboratories, encountered during operations was so overwhelming that no intelligence agency of reasonable size could handle it all. A very thorough job could be done, however, on such scientific subjects for which there existed at home or in the field a definite demand for intelligence information. For this reason, the Alsos Mission, more or less automatically, restricted its investigations to the following subjects:

a. The Uranium Problem
b. Bacteriological Warfare
c. Organization of Enemy Scientific Research
d. Aeronautical Research
e. Proximity Fuzes
f. German Research Facilities for Guided Missiles
g. The Speer Ministry's Interest in Research
h. Chemical Research
i. Metallurgical Research
j. Shale Oil Development
k. Miscellaneous Intelligence

The Policy on Scientific Personnel

At the time the Alsos Mission was being organized, it seemed impossible to predict the problems which such a mission would encounter in its field operations. Not until the fall of Strasbourg in November 1944 did one get an insight into the work which had to be done when entering Germany. This general uncertainty explains the changes which were necessary in the choice of scientific personnel for the Mission.

The original recommendation was that the Scientific Chief would be the only permanent civilian member of the Mission. Whenever important targets were uncovered, the Office of Field Service of the Office of Scientific Research and Development would send expert scientists to the Mission for exploitation of the target. For this purpose, the Office of Field Service alerted about forty key scientists.

It soon developed that the original scheme could not be followed. Experience in France showed that the key scientists attached to the Mission

Report by the Scientific Chief of the Alsos Mission

DECLASSIFIED
Authority NND 933079

could seldom be made available at the right instant, especially during rapid advances of the Allied forces. Those key scientists who did join the Mission could not be spared long enough from their research projects at home to insure continuity of action. Moreover, several of the research project leaders were convinced that so little could be learned from a study of German war research that they were unwilling permanently to divert their experts to such investigations. As a result of this policy, only the Scientific Chief and one expert on the Uranium problem (Wardenburg) were on hand at the fall of Strasbourg. They were followed shortly by two military experts on Bacteriological Warfare (Capts. Cromartie and Henze). The exhaustive information on these two subjects, which was collected there, indicated that, if more scientists had been present, a multitude of significant scientific intelligence in other fields would have been found.

After this, at the urgent request of the Scientific Chief, a few scientists were attached to the Mission permanently (Colby, Baumann, Smyth, Kuiper). These men were responsible to the Mission only and to no other war research project at home. They were selected for their ability as all-round scientists capable of judging the importance of research work even when it did not pertain to their own fields of specialization. Of great importance in their selection was their thorough knowledge of the German language and German scientific institutions.

Those special war research projects, which considered the work of sufficient value to support it by continuous representation on the Mission, were also accommodated, the principal examples being the Bacteriological Warfare Division (Capt. Cromartie et al), the Uranium Project (Wardenburg et al), the National Advisory Council on Aeronautics (Reid et al) and the Petroleum Division of the Quarter Master General (Lt. Col. Foran).

-3-

Experts attached to the Mission for a short term were accepted only when there was a very definite need for them and when their activities did not interfere with the Mission's sufficient, but not inexhaustible, means of transportation. In addition, the War Department attached to the Mission a few teams whose interests were somewhat outside the field of scientific intelligence.

The Office of Field Service, in March 1945, assigned a Deputy Scientific Chief (Kemble) and a Technical Aide (Kelly) to the Mission. The task of the former was to represent the Scientific Chief whenever he was away on field investigations.

At the request of the Scientific Chief, a few more scientists were sent over in the summer of 1945 to assist in the reading and evaluation of numerous captured German documents (Van Klooster, Beth, Helmkamp, Wannier, Van de Kamp).

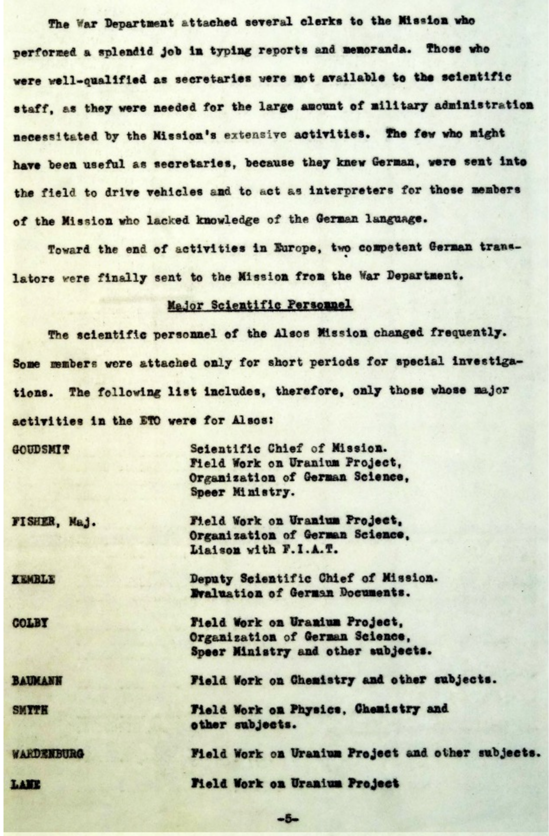
A highly valuable and unique position in the Alsos Mission was held by Major R. A. Fisher. He was both a scientist and a member of the military administrative staff of Alsos. This combination proved to be extremely useful.

Whenever expedient, members of other intelligence organizations were temporarily attached to the Alsos Mission. Most of the investigation on the enemy's proximity fuse development was performed with such temporary personnel under the leadership of Dr. E. O. Salant.

The fact that the Mission had but one civilian secretary (except for the last two months when there were two) proved to be a serious handicap. It is no wonder, therefore, that the Technical Aide and the Deputy Scientific Chief complained that much of the work they were obliged to do could have been performed by an additional competent secretary.

-4-

Figure D.32: Samuel A. Goudsmit. 7 December 1945. Report by the Scientific Chief of the Alsos Mission [NARA RG GOUDS, Entry UD-7420, Box 6, Folder Alsos Mission].



The War Department attached several clerks to the Mission who performed a splendid job in typing reports and memoranda. Those who were well-qualified as secretaries were not available to the scientific staff, as they were needed for the large amount of military administration necessitated by the Mission's extensive activities. The few who might have been useful as secretaries, because they knew German, were sent into the field to drive vehicles and to act as interpreters for those members of the Mission who lacked knowledge of the German language.

Toward the end of activities in Europe, two competent German translators were finally sent to the Mission from the War Department.

Major Scientific Personnel

The scientific personnel of the Alsos Mission changed frequently. Some members were attached only for short periods for special investigations. The following list includes, therefore, only those whose major activities in the ETO were for Alsos:

GOUDSMIT	Scientific Chief of Mission. Field Work on Uranium Project, Organization of German Science, Speer Ministry.
FISHER, Maj.	Field Work on Uranium Project, Organization of German Science, Liaison with F.I.A.T.
KEMBLE	Deputy Scientific Chief of Mission. Evaluation of German Documents.
COLBY	Field Work on Uranium Project, Organization of German Science, Speer Ministry and other subjects.
BAUMANN	Field Work on Chemistry and other subjects.
SMITH	Field Work on Physics, Chemistry and other subjects.
WARDENBURG	Field Work on Uranium Project and other subjects.

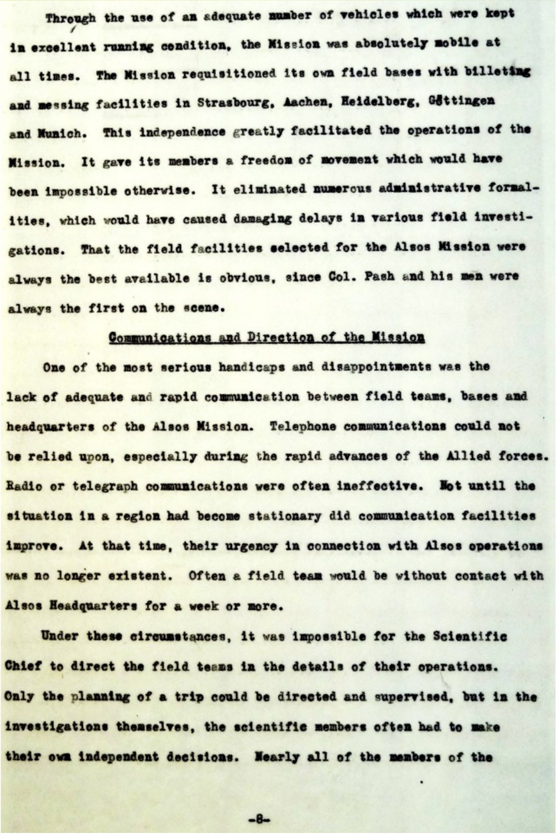
Relations Between the Scientific and Military Groups

Almost from the very beginning of operations in France, a clear understanding was reached concerning the division of responsibility between the military and the scientific groups of the Alsos Mission.

The task of the scientists was to analyze and evaluate all available material which led to personalities and locations of interest to scientific intelligence. The task of the military was to plan and execute operations, to secure the personalities and locations indicated by the scientific staff and to enable the scientists to investigate these targets.

This arrangement worked out perfectly. Never did the military group question the judgment of the scientific group as to the importance of a target, and never did they fail to execute the operations as needed and planned. It was essential, however, that the Military Chief (Col. B. T. Pash) be given, before each operation, as complete a picture of the scientific interests as possible. A mere description and enumeration of the targets would have been insufficient. On the other hand, the scientists were sometimes handicapped by not always being fully informed of military advances, as the relative importance of targets often depended upon the order in which they might be captured.

-7-



Through the use of an adequate number of vehicles which were kept in excellent running condition, the Mission was absolutely mobile at all times. The Mission requisitioned its own field bases with billeting and messing facilities in Strasbourg, Aachen, Heidelberg, Göttingen and Munich. This independence greatly facilitated the operations of the Mission. It gave its members a freedom of movement which would have been impossible otherwise. It eliminated numerous administrative formalities, which would have caused damaging delays in various field investigations. That the field facilities selected for the Alsos Mission were always the best available is obvious, since Col. Pash and his men were always the first on the scene.

Communications and Direction of the Mission

One of the most serious handicaps and disappointments was the lack of adequate and rapid communication between field teams, bases and headquarters of the Alsos Mission. Telephone communications could not be relied upon, especially during the rapid advances of the Allied forces. Radio or telegraph communications were often ineffective. Not until the situation in a region had become stationary did communication facilities improve. At that time, their urgency in connection with Alsos operations was no longer existent. Often a field team would be without contact with Alsos Headquarters for a week or more.

Under these circumstances, it was impossible for the Scientific Chief to direct the field teams in the details of their operations. Only the planning of a trip could be directed and supervised, but in the investigations themselves, the scientific members often had to make their own independent decisions. Nearly all of the members of the

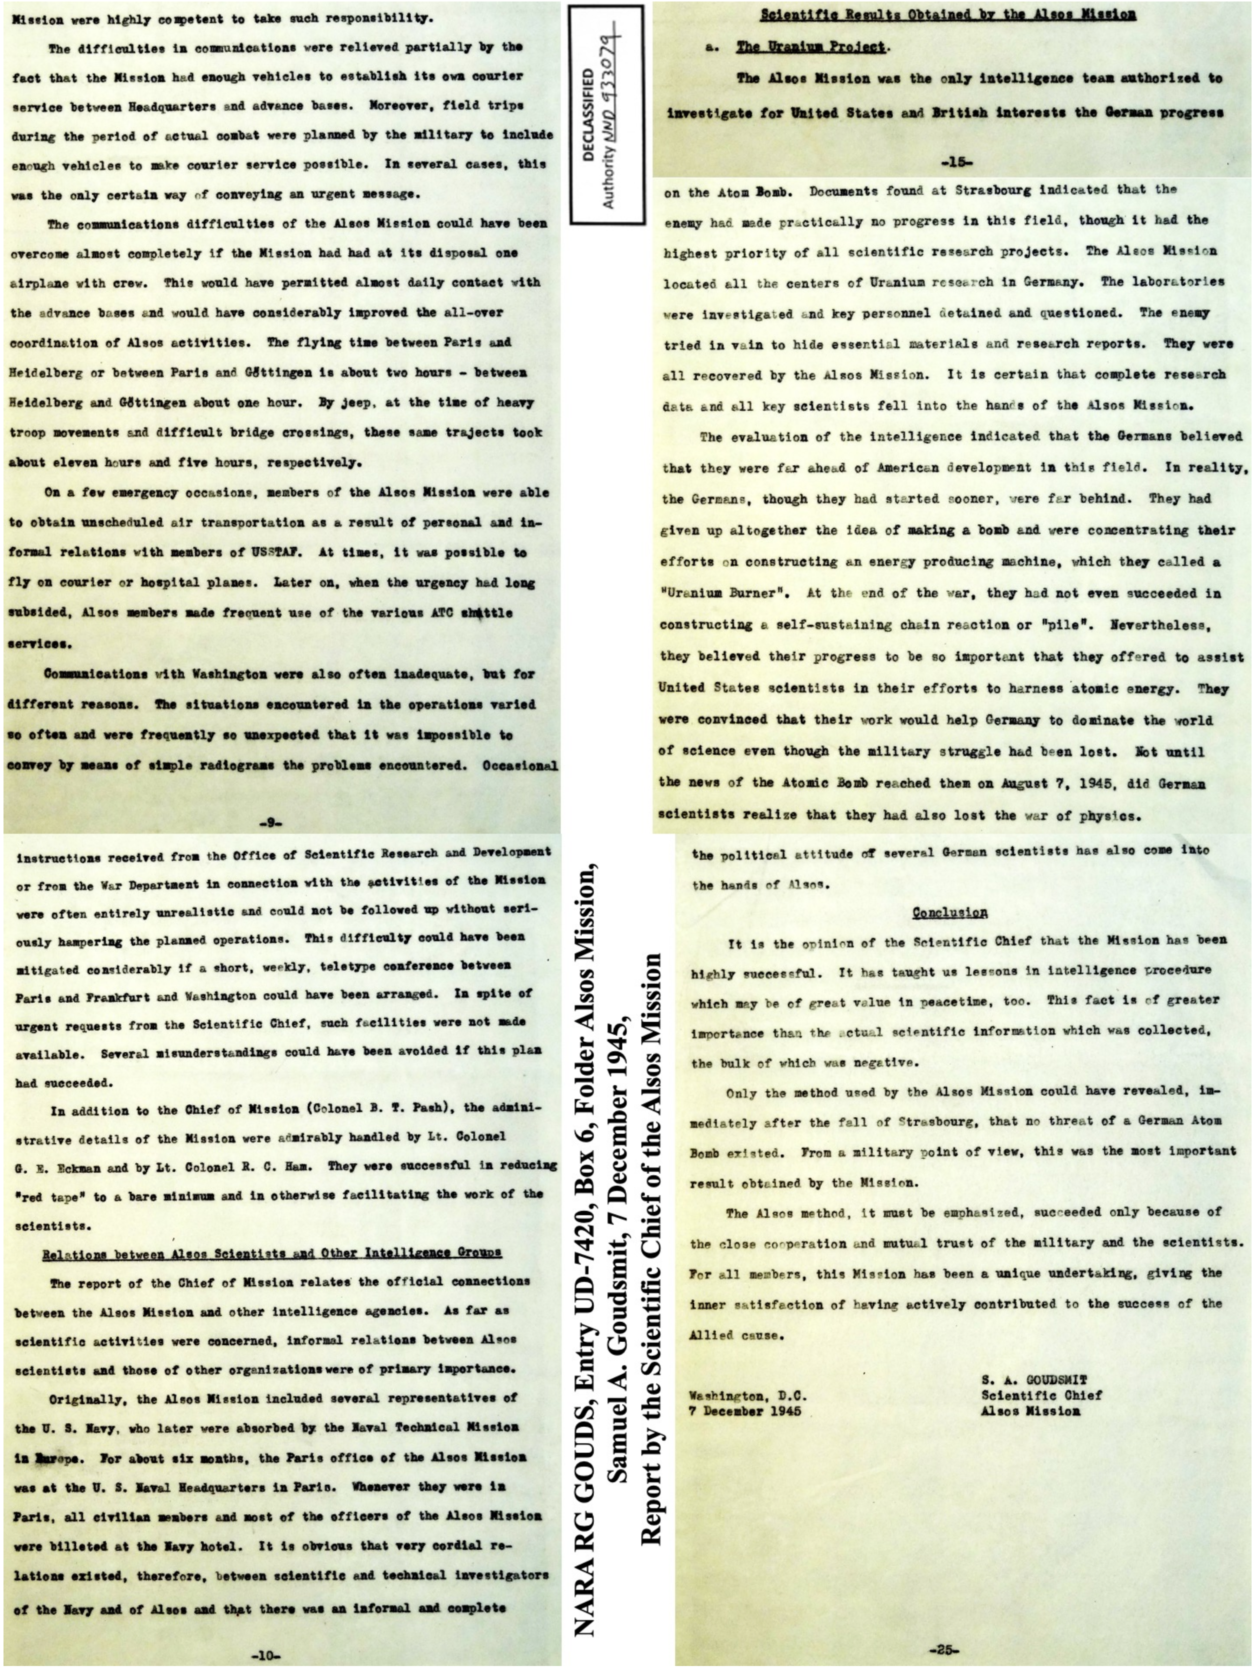
Figure D.33: Samuel A. Goudsmit. 7 December 1945. Report by the Scientific Chief of the Alsos Mission [NARA RG GOUDS, Entry UD-7420, Box 6, Folder Alsos Mission].



Mission were highly competent to take such responsibility.

The difficulties in communications were relieved partially by the fact that the Mission had enough vehicles to establish its own courier service between Headquarters and advance bases. Moreover, field trips during the period of actual combat were planned by the military to include enough vehicles to make courier service possible. In several cases, this was the only certain way of conveying an urgent message.

The communications difficulties of the Alsos Mission could have been overcome almost completely if the Mission had had at its disposal one airplane with crew. This would have permitted almost daily contact with the advance bases and would have considerably improved the all-over coordination of Alsos activities. The flying time between Paris and Heidelberg or between Paris and Göttingen is about two hours - between Heidelberg and Göttingen about one hour. By jeep, at the time of heavy troop movements and difficult bridge crossings, these same trajects took about eleven hours and five hours, respectively.

On a few emergency occasions, members of the Alsos Mission were able to obtain unscheduled air transportation as a result of personal and informal relations with members of USSTAF. At times, it was possible to fly on courier or hospital planes. Later on, when the urgency had long subsided, Alsos members made frequent use of the various ATC shuttle services.

Communications with Washington were also often inadequate, but for different reasons. The situations encountered in the operations varied so often and were frequently so unexpected that it was impossible to convey by means of simple radiograms the problems encountered. Occasional instructions received from the Office of Scientific Research and Development or from the War Department in connection with the activities of the Mission were often entirely unrealistic and could not be followed up without seriously hampering the planned operations. This difficulty could have been mitigated considerably if a short, weekly, teletype conference between Paris and Frankfurt and Washington could have been arranged. In spite of urgent requests from the Scientific Chief, such facilities were not made available. Several misunderstandings could have been avoided if this plan had succeeded.

-9-

In addition to the Chief of Mission (Colonel B. T. Pash), the administrative details of the Mission were admirably handled by Lt. Colonel G. E. Eckman and by Lt. Colonel R. C. Ham. They were successful in reducing "red tape" to a bare minimum and in otherwise facilitating the work of the scientists.

Relations between Alsos Scientists and Other Intelligence Groups

The report of the Chief of Mission relates the official connections between the Alsos Mission and other intelligence agencies. As far as scientific activities were concerned, informal relations between Alsos scientists and those of other organizations were of primary importance.

Originally, the Alsos Mission included several representatives of the U. S. Navy, who later were absorbed by the Naval Technical Mission in Europe. For about six months, the Paris office of the Alsos Mission was at the U. S. Naval Headquarters in Paris. Whenever they were in Paris, all civilian members and most of the officers of the Alsos Mission were billeted at the Navy hotel. It is obvious that very cordial relations existed, therefore, between scientific and technical investigators of the Navy and of Alsos and that there was an informal and complete

Scientific Results Obtained by the Alsos Mission

a. The Uranium Project.

The Alsos Mission was the only intelligence team authorized to investigate for United States and British interests the German progress

-15-

on the Atom Bomb. Documents found at Strasbourg indicated that the enemy had made practically no progress in this field, though it had the highest priority of all scientific research projects. The Alsos Mission located all the centers of Uranium research in Germany. The laboratories were investigated and key personnel detained and questioned. The enemy tried in vain to hide essential materials and research reports. They were all recovered by the Alsos Mission. It is certain that complete research data and all key scientists fell into the hands of the Alsos Mission.

The evaluation of the intelligence indicated that the Germans believed that they were far ahead of American development in this field. In reality, the Germans, though they had started sooner, were far behind. They had given up altogether the idea of making a bomb and were concentrating their efforts on constructing an energy producing machine, which they called a "Uranium Burner". At the end of the war, they had not even succeeded in constructing a self-sustaining chain reaction or "pile". Nevertheless, they believed their progress to be so important that they offered to assist United States scientists in their efforts to harness atomic energy. They were convinced that their work would help Germany to dominate the world of science even though the military struggle had been lost. Not until the news of the Atomic Bomb reached them on August 7, 1945, did German scientists realize that they had also lost the war of physics.

the political attitude of several German scientists has also come into the hands of Alsos.

Conclusion

It is the opinion of the Scientific Chief that the Mission has been highly successful. It has taught us lessons in intelligence procedure which may be of great value in peacetime, too. This fact is of greater importance than the actual scientific information which was collected, the bulk of which was negative.

Only the method used by the Alsos Mission could have revealed, immediately after the fall of Strasbourg, that no threat of a German Atom Bomb existed. From a military point of view, this was the most important result obtained by the Mission.

The Alsos method, it must be emphasized, succeeded only because of the close cooperation and mutual trust of the military and the scientists. For all members, this Mission has been a unique undertaking, giving the inner satisfaction of having actively contributed to the success of the Allied cause.

I have read the accompanying articles and comments. A reading of Dr. Goudsmits Senate Testimon showed me that he kept within his testimony on all points in his articles. It is unfortunate, but unpreventable, that the newspaper article threw the wrong emphasis on Himlers plans for continuing atomic energy in the Bavarian Redoubt. Nevertheless it is true.

I feel Goudsmit is doing us a service by showing the value of our MED organization. It would be utter stupidity to alienate one of the few friends we have among the Atomic Scientists by calling him to task for this.

FAILURE OF GERMAN URANIUM RESEARCH - A DOCUMENTARY
STORY ON THE DECLINE OF GERMAN SCIENCE DURING THE WAR

by S. A. Goudsmit

If the Germans, before their surrender, had written a "Smyth Report" of their own, it would have been most instructive to compare the German handling of atomic bomb research with the American. Such a report would have brought out the mistakes that doomed the German effort to failure, mistakes which we might have made ourselves and may still make in the future.

There is no German equivalent of our "Smyth Report". But, we can, from the documents and authentic information at our disposal, construct one, though it will lack the tone of optimism and confidence the Germans would have given it. For, Germany's scientists were certain they had left the Allies far behind in the race. Her physicists seriously believed that their results were so important that they could be used to buy a soft peace. The Germans attempted to keep their nuclear research secret and their documents hidden from the Allied experts. As for Allied research, they had not the faintest notion of either its nature or its extent. The news of Hiroshima took the German scientists completely by surprise. It was a greater blow to them than the military defeat.

The most fatal mistake the Germans made was to appoint to key administrative positions in the scientific organization men utterly inadequate to the tasks involved. Active creative scientists are not essential for administrative tasks, but those responsible for policymaking must possess vision and sound judgment. Judgment especially is necessary in choosing advisors and in delegating power. The United States might fall into the same

error by having science controlled by a committee selected solely on the basis of its political or military affiliations. ~~In a letter to a colleague about the original Kilgore Bill of 1942, which proposed government control of science, a German physicist declared that the bill "would kill science in America just as it had been in Germany."~~

Another mistake, one especially typical of one phase of the German Atom Bomb Project, was that of making it a "one-man show". The principal work on the project was dominated by one man, Heisenberg, whose ideas determined what course the uranium research should take. Heisenberg is truly one of the world's greatest physicists and a foremost expert on atomic problems, but a uranium project is beyond the capacities of any single scientist, no matter how eminent. One gathers the impression, however, that the scientists cooperating with Heisenberg never doubted his judgment. In the Allied project, on the contrary, the clashes of opinion among the key scientists were essential to its ultimate success; Oppenheimer was not surrounded by a group of "yes-men".

-3-

To understand the extent of the German failure, we must know something out the organization of scient c research in Germany. During the first half of the war, research in pure science was supervised by a Research Council sponsored by the Department of Education under Minister Rust. The council members were usually competent representatives of the various fields of science. The chairman of the council, Dr. Rudolf Mentzel, was, however, a second-rate chemist whose administrative ability was as totally inadequate as his scientific skill for such a comprehensive task. He was favored by being made-? a brigadier general in Himmler's SS.

Practically no war research was done in the early days. Most scientists were drafted into the Army, as they were not considered essential to the war effort. It was thought that the war would last such a short time that new developments were unnecessary.

In 1943, when it became evident that the war would last longer than the Germans had originally anticipated, the Research Council was taken out of the Department of Education and placed directly under Reichsmarshal Göring. The incompetent Mentzel stayed on as Chief Administrator, however, and the reorganization did not improve the quality of research in its relation to the war effort.

A new figure appeared on the horizon of scientific organization. He was likewise a second-rater, an engineer from Hannover named Osenberg. He had an almost psychopathic mania for organization charts and card files. German scientists had expressed in

Figure D.36: Samuel Goudsmit. Failure of German Uranium Research—A Documentary Story of the Decline of German Science During the War. June 1946 draft article for publication [NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)].

-4-

talks and in writing a great admiration for the United States' Roster of Scientific Personnel and believed that the appointment of Osenberg as chief of a newly created personnel office would solve all their problems. He did, indeed, succeed in convincing the authorities that scientific personnel were more valuable in the laboratory than in the armed forces, and, as a result, a few thousand scientists were released in 1944. At the end of 1944, Göring ordered him to create a unified research organization, comprising all the research facilities of the armed forces, of industry, and of academic institutions. Osenberg gave himself the two? most powerful positions in this "War Research Association", which existed on paper only. Neither industry nor the armed forces cooperated. When Osenberg and his files were captured and removed to Paris for investigation, he was convinced that the Allies would continue to use his services and merely changed his business letterhead to read "z. Zt. Paris" (temporarily in Paris).

Not all research was centralized in the Research Council. More successful in their organization from the very start was the Research Department of the German Air Force. Here, men of vision were in charge, and Nazi party affiliation was not essential. To the very end, they remained totally independent of the other research organizations.

The German Navy had an independent research department which limited its efforts to Navy interests and, towards the end of the war, did excellent work on U-boat problems.

-5-

Chief of Army Research was a certain Professor Erich Schumann. He was Director of the Second Physics Institute of Berlin University, where secret war work had already been in progress for several years before the war. He held the chair for "Military Physics", though his few publications dealt with the physics of musical instruments. His colleagues dubbed him "Professor of Military Music". In 1944, General Keitel, the Chief of Staff, appointed Schumann head of all war research for the armed forces.

Of other research organizations, the only one of interest for this article was the Research Section of the Postal Department, whose normal function was communications research. The Postal Minister was an engineer, Ohnesorge, who not only had the confidence of Hitler but who also managed to be on good terms with Himmler. Needless to say, his judgment on scientific questions was poor.

There was no lack of funds. The Research Council had more than it was able to spend. Half of the 50 million marks available for research in 1944 was not used. The principal expenditures were for research in electronics and the uranium project--about 5 million marks for each.

No description is complete without mentioning the activities of the Gestapo with respect to the Research Program. Osenberg derived his power chiefly from the fact that he was a top member of Section IIIC, the "cultural" department of Himmler's SD. Files which he tried to hide showed that, in all institutes and at all meetings, he had informers who reported to him on the value of the research, the personal obstacles, the lack of progress, the flaws in organization, and similar gossip.

-6-

The incompetents who headed the research effort caused serious trouble for the scientists. Money and apparatus were given to crackpots. There were actually held meetings to decide whether certain fields of physics conformed with Nazi philosophy. Such activities hampered the work of the real scientists, who usually found themselves on the wrong side of the argument.

Early in 1939, soon after the discovery of uranium fission by Otto Hahn, physicists in many countries tried to draw the attention of government authorities to the unusual importance of the uranium problem and its probable military implications. In Germany, official recognition of the problem came sooner than it did in the United States.

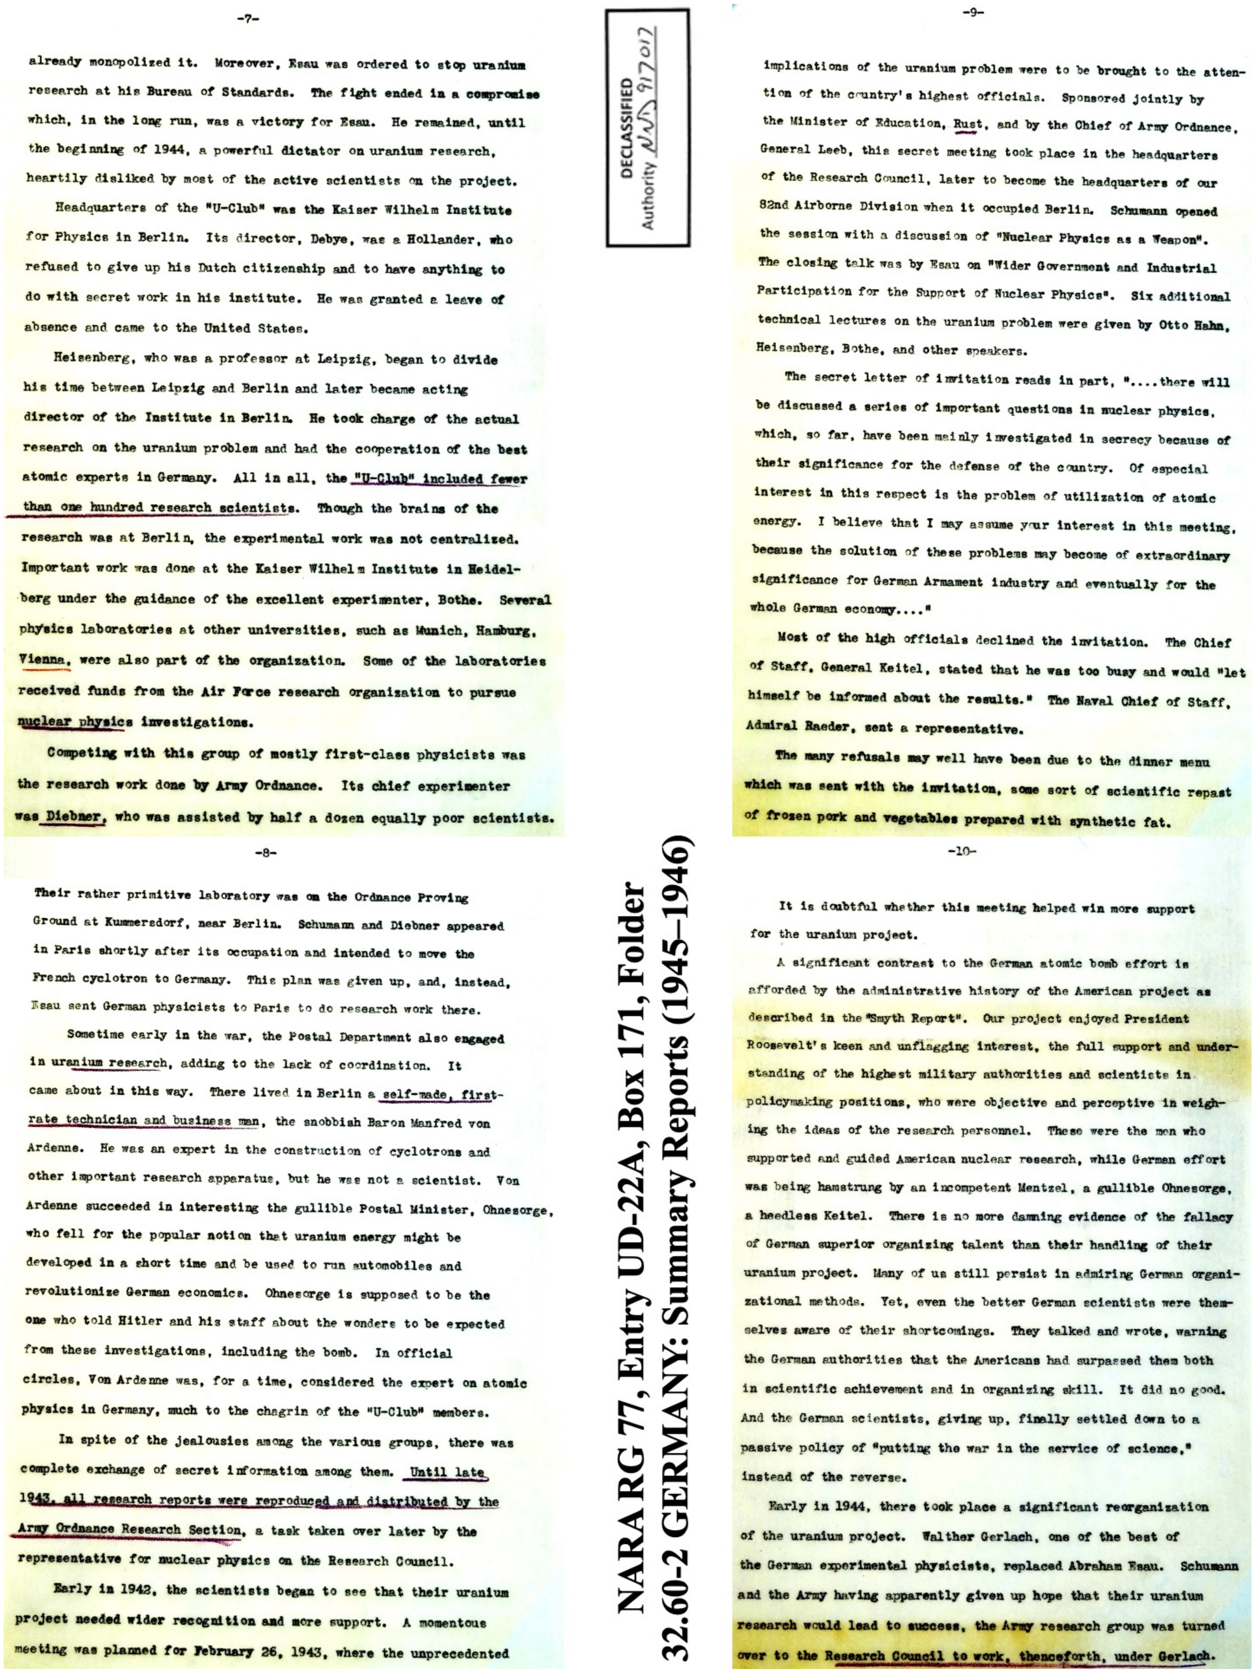
The Army Ordnance Research Section under Schumann began immediate secret research on the possibilities of an atom bomb. Independently, a group of six physicists, in April 1939, held a secret meeting, sponsored by the Department of Education's Research Council. They decided to create an informal secret "Uranium Club" made up of scientists who would concentrate their efforts on the atomic bomb and energy problem. Otto Hahn and Heisenberg were not present at this original meeting, joining the "U-Club" later.

In the summer of 1939, Heisenberg was invited to the United States. Back in Germany, he reported, on the basis of his observations, that there was no official interest in the uranium problem in the United States in spite of the extensive nuclear physics research being carried on at all American universities. Another visitor, the nuclear physicist Bothe, also travelled around the country that summer, probably equally surprised at what he thought was our lack of insight. Though Heisenberg and Bothe saw practically all physicists in the country, they kept the existence of [illegible] German "U-Club" a secret and did not drop the slightest hint that they were actively working on the uranium problem.

Chief of the "U-Club" was one Abraham Esau. He was president of the German equivalent of our Bureau of Standards, representative for physics on the Research Council, and an ardent Nazi. But, he was a complete outsider in matters of atomic physics.

In September 1939 came the inevitable clash between Esau and Schumann. Esau wanted to earmark all available uranium for his experiments but discovered, to his surprise, that Army Ordnance had

Figure D.37: Samuel Goudsmit. Failure of German Uranium Research—A Documentary Story of the Decline of German Science During the War. June 1946 draft article for publication [NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)].



-7-

already monopolized it. Moreover, Esau was ordered to stop uranium research at his Bureau of Standards. The fight ended in a compromise which, in the long run, was a victory for Esau. He remained, until the beginning of 1944, a powerful dictator on uranium research, heartily disliked by most of the active scientists on the project.

Headquarters of the "U-Club" was the Kaiser Wilhelm Institute for Physics in Berlin. Its director, Debye, was a Hollander, who refused to give up his Dutch citizenship and to have anything to do with secret work in his institute. He was granted a leave of absence and came to the United States.

Heisenberg, who was a professor at Leipzig, began to divide his time between Leipzig and Berlin and later became acting director of the Institute in Berlin. He took charge of the actual research on the uranium problem and had the cooperation of the best atomic experts in Germany. All in all, the "U-Club" included fewer than one hundred research scientists. Though the brains of the research was at Berlin, the experimental work was not centralized. Important work was done at the Kaiser Wilhelm Institute in Heidelberg under the guidance of the excellent experimenter, Bothe. Several physics laboratories at other universities, such as Munich, Hamburg, Vienna, were also part of the organization. Some of the laboratories received funds from the Air Force research organization to pursue nuclear physics investigations.

Competing with this group of mostly first-class physicists was the research work done by Army Ordnance. Its chief experimenter was Diebner, who was assisted by half a dozen equally poor scientists.

-8-

Their rather primitive laboratory was on the Ordnance Proving Ground at Kummersdorf, near Berlin. Schumann and Diebner appeared in Paris shortly after its occupation and intended to move the French cyclotron to Germany. This plan was given up, and, instead, Esau sent German physicists to Paris to do research work there.

Sometime early in the war, the Postal Department also engaged in uranium research, adding to the lack of coordination. It came about in this way. There lived in Berlin a self-made, first-rate technician and business man, the snobbish Baron Manfred von Ardenne. He was an expert in the construction of cyclotrons and other important research apparatus, but he was not a scientist. Von Ardenne succeeded in interesting the gullible Postal Minister, Ohnesorge, who fell for the popular notion that uranium energy might be developed in a short time and be used to run automobiles and revolutionize German economics. Ohnesorge is supposed to be the one who told Hitler and his staff about the wonders to be expected from these investigations, including the bomb. In official circles, Von Ardenne was, for a time, considered the expert on atomic physics in Germany, much to the chagrin of the "U-Club" members.

In spite of the jealousies among the various groups, there was complete exchange of secret information among them. Until late 1943, all research reports were reproduced and distributed by the Army Ordnance Research Section, a task taken over later by the representative for nuclear physics on the Research Council.

Early in 1942, the scientists began to see that their uranium project needed wider recognition and more support. A momentous meeting was planned for February 26, 1943, where the unprecedented

DECLASSIFIED
Authority NND 917017

-9-

implications of the uranium problem were to be brought to the attention of the country's highest officials. Sponsored jointly by the Minister of Education, Rust, and by the Chief of Army Ordnance, General Leeb, this secret meeting took place in the headquarters of the Research Council, later to become the headquarters of our 82nd Airborne Division when it occupied Berlin. Schumann opened the session with a discussion of "Nuclear Physics as a Weapon". The closing talk was by Esau on "Wider Government and Industrial Participation for the Support of Nuclear Physics". Six additional technical lectures on the uranium problem were given by Otto Hahn, Heisenberg, Bothe, and other speakers.

The secret letter of invitation reads in part, "....there will be discussed a series of important questions in nuclear physics, which, so far, have been mainly investigated in secrecy because of their significance for the defense of the country. Of especial interest in this respect is the problem of utilization of atomic energy. I believe that I may assume your interest in this meeting, because the solution of these problems may become of extraordinary significance for German Armament industry and eventually for the whole German economy...."

Most of the high officials declined the invitation. The Chief of Staff, General Keitel, stated that he was too busy and would "let himself be informed about the results." The Naval Chief of Staff, Admiral Raeder, sent a representative.

The many refusals may well have been due to the dinner menu which was sent with the invitation, some sort of scientific repast of frozen pork and vegetables prepared with synthetic fat.

-10-

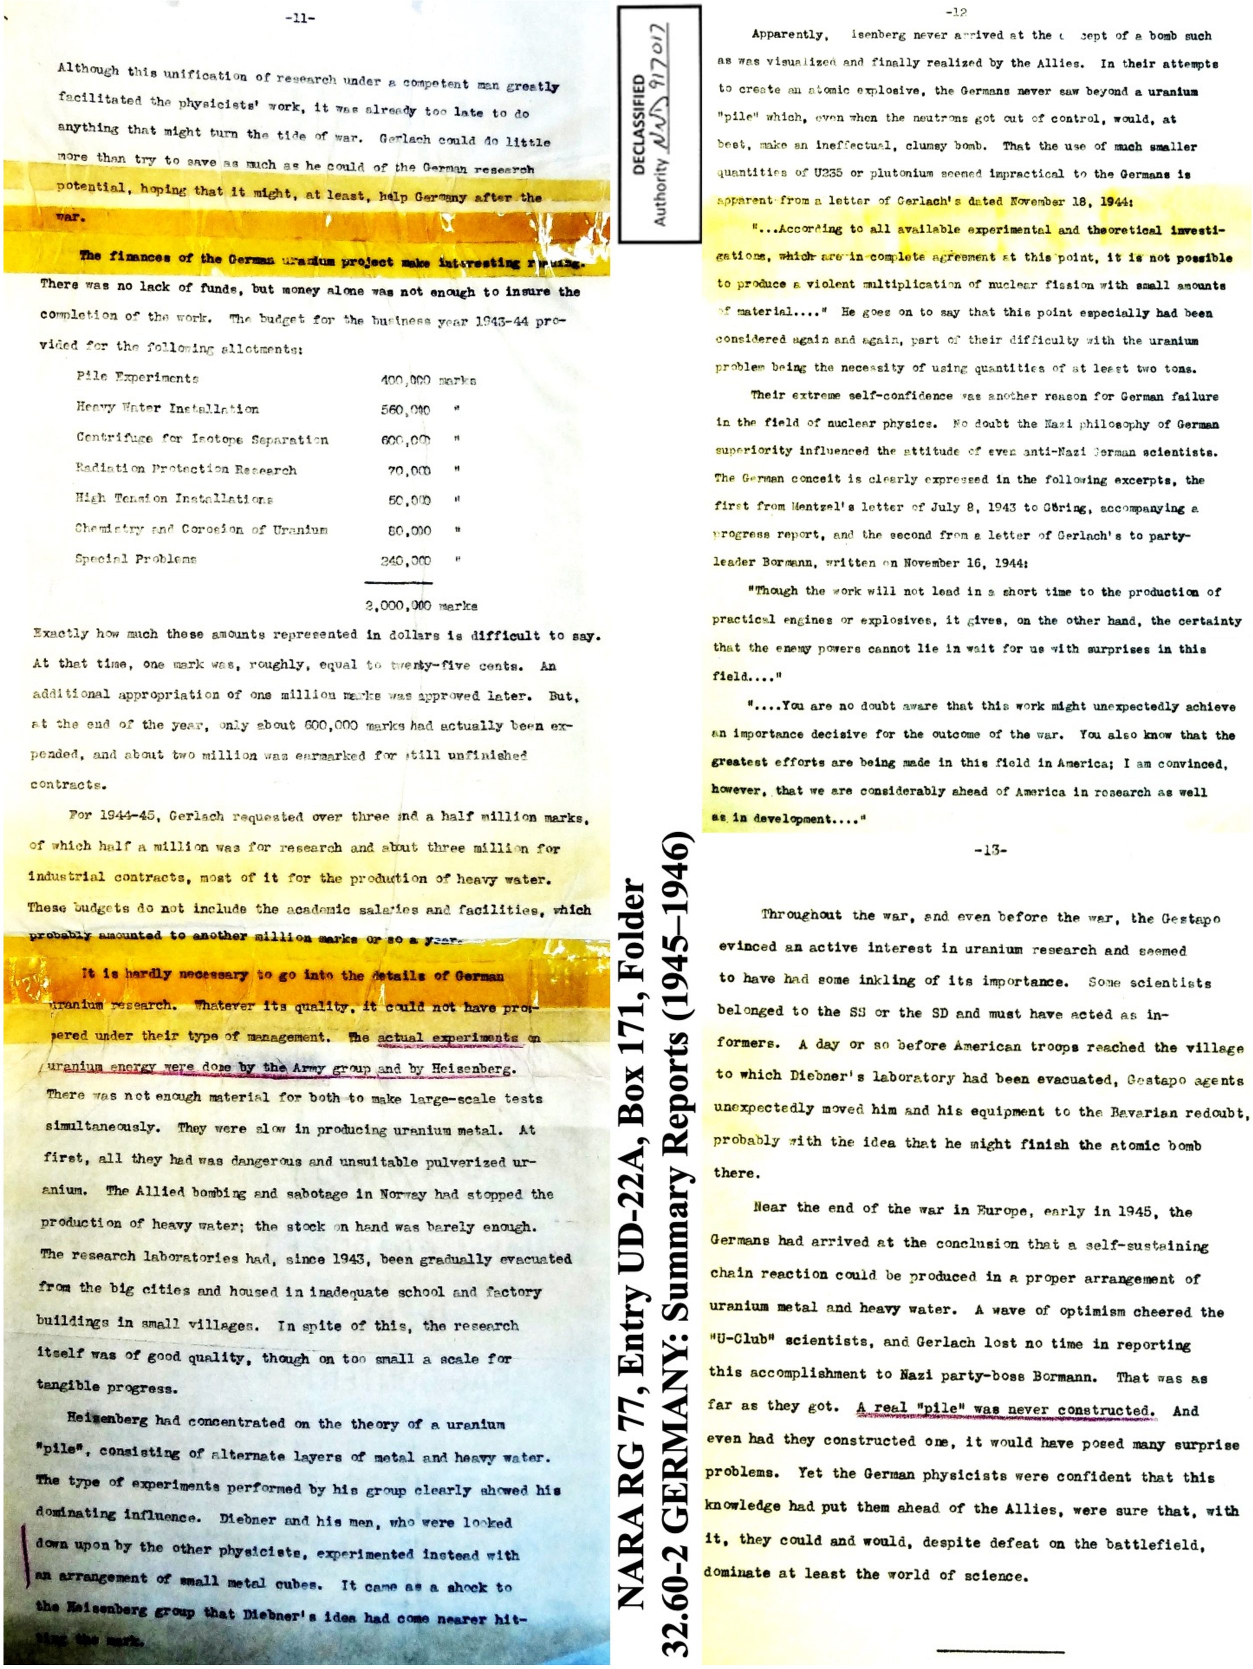
It is doubtful whether this meeting helped win more support for the uranium project.

A significant contrast to the German atomic bomb effort is afforded by the administrative history of the American project as described in the "Smyth Report". Our project enjoyed President Roosevelt's keen and unflagging interest, the full support and understanding of the highest military authorities and scientists in policymaking positions, who were objective and perceptive in weighing the ideas of the research personnel. These were the men who supported and guided American nuclear research, while German effort was being hamstrung by an incompetent Mentzel, a gullible Ohnesorge, a heedless Keitel. There is no more damning evidence of the fallacy of German superior organizing talent than their handling of their uranium project. Many of us still persist in admiring German organizational methods. Yet, even the better German scientists were themselves aware of their shortcomings. They talked and wrote, warning the German authorities that the Americans had surpassed them both in scientific achievement and in organizing skill. It did no good. And the German scientists, giving up, finally settled down to a passive policy of "putting the war in the service of science," instead of the reverse.

Early in 1944, there took place a significant reorganization of the uranium project. Walther Gerlach, one of the best of the German experimental physicists, replaced Abraham Esau. Schumann and the Army having apparently given up hope that their uranium research would lead to success, the Army research group was turned over to the Research Council to work, thenceforth, under Gerlach.

NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)

Figure D.38: Samuel Goudsmit. Failure of German Uranium Research—A Documentary Story of the Decline of German Science During the War. June 1946 draft article for publication [NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)].



-11-

Although this unification of research under a competent man greatly facilitated the physicists' work, it was already too late to do anything that might turn the tide of war. Gerlach could do little more than try to save as much as he could of the German research potential, hoping that it might, at least, help Germany after the war.

The finances of the German uranium project make interesting reading. There was no lack of funds, but money alone was not enough to insure the completion of the work. The budget for the business year 1943-44 provided for the following allotments:

Pile Experiments	400,000 marks
Heavy Water Installation	560,000 "
Centrifuge for Isotope Separation	600,000 "
Radiation Protection Research	70,000 "
High Tension Installations	50,000 "
Chemistry and Corosion of Uranium	80,000 "
Special Problems	240,000 "
	2,000,000 marks

Exactly how much these amounts represented in dollars is difficult to say. At that time, one mark was, roughly, equal to twenty-five cents. An additional appropriation of one million marks was approved later. But, at the end of the year, only about 600,000 marks had actually been expended, and about two million was earmarked for still unfinished contracts.

For 1944-45, Gerlach requested over three and a half million marks, of which half a million was for research and about three million for industrial contracts, most of it for the production of heavy water. These budgets do not include the academic salaries and facilities, which probably amounted to another million marks or so a year.

It is hardly necessary to go into the details of German uranium research. Whatever its quality, it could not have prospered under their type of management. The actual experiments on uranium energy were done by the Army group and by Heisenberg. There was not enough material for both to make large-scale tests simultaneously. They were slow in producing uranium metal. At first, all they had was dangerous and unsuitable pulverized uranium. The Allied bombing and sabotage in Norway had stopped the production of heavy water; the stock on hand was barely enough. The research laboratories had, since 1943, been gradually evacuated from the big cities and housed in inadequate school and factory buildings in small villages. In spite of this, the research itself was of good quality, though on too small a scale for tangible progress.

Heisenberg had concentrated on the theory of a uranium "pile", consisting of alternate layers of metal and heavy water. The type of experiments performed by his group clearly showed his dominating influence. Diebner and his men, who were looked down upon by the other physicists, experimented instead with an arrangement of small metal cubes. It came as a shock to the Heisenberg group that Diebner's idea had come nearer hitting the mark.

DECLASSIFIED
Authority NND 917017

NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)

-12-

Apparently, Heisenberg never arrived at the concept of a bomb such as was visualized and finally realized by the Allies. In their attempts to create an atomic explosive, the Germans never saw beyond a uranium "pile" which, even when the neutrons got out of control, would, at best, make an ineffectual, clumsy bomb. That the use of much smaller quantities of U235 or plutonium seemed impractical to the Germans is apparent from a letter of Gerlach's dated November 18, 1944:

"...According to all available experimental and theoretical investigations, which are in complete agreement at this point, it is not possible to produce a violent multiplication of nuclear fission with small amounts of material...." He goes on to say that this point especially had been considered again and again, part of their difficulty with the uranium problem being the necessity of using quantities of at least two tons.

Their extreme self-confidence was another reason for German failure in the field of nuclear physics. No doubt the Nazi philosophy of German superiority influenced the attitude of even anti-Nazi German scientists. The German conceit is clearly expressed in the following excerpts, the first from Mentzel's letter of July 8, 1943 to Göring, accompanying a progress report, and the second from a letter of Gerlach's to party-leader Bormann, written on November 16, 1944:

"Though the work will not lead in a short time to the production of practical engines or explosives, it gives, on the other hand, the certainty that the enemy powers cannot lie in wait for us with surprises in this field...."

"....You are no doubt aware that this work might unexpectedly achieve an importance decisive for the outcome of the war. You also know that the greatest efforts are being made in this field in America; I am convinced, however, that we are considerably ahead of America in research as well as in development...."

-13-

Throughout the war, and even before the war, the Gestapo evinced an active interest in uranium research and seemed to have had some inkling of its importance. Some scientists belonged to the SS or the SD and must have acted as informers. A day or so before American troops reached the village to which Diebner's laboratory had been evacuated, Gestapo agents unexpectedly moved him and his equipment to the Bavarian redoubt, probably with the idea that he might finish the atomic bomb there.

Near the end of the war in Europe, early in 1945, the Germans had arrived at the conclusion that a self-sustaining chain reaction could be produced in a proper arrangement of uranium metal and heavy water. A wave of optimism cheered the "U-Club" scientists, and Gerlach lost no time in reporting this accomplishment to Nazi party-boss Bormann. That was as far as they got. A real "pile" was never constructed. And even had they constructed one, it would have posed many surprise problems. Yet the German physicists were confident that this knowledge had put them ahead of the Allies, were sure that, with it, they could and would, despite defeat on the battlefield, dominate at least the world of science.

Figure D.39: Samuel Goudsmit. Failure of German Uranium Research—A Documentary Story of the Decline of German Science During the War. June 1946 draft article for publication [NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 GERMANY: Summary Reports (1945–1946)].

Samuel A. Goudsmit. 1947. *Alsos.* New York: Henry Schuman.

[pp. 11–12]: If only we could get hold of a German atomic physicist, we felt, we could soon find out what the rest of them were up to. To us physicists the problem seemed very simple. Even those of us who were not working on the atom bomb project knew pretty well what was going on over here. No amount of military security could have prevented us from knowing, difficult as it was for the military to understand this. Active scientists engaged in the same general field of research inevitably form a kind of clan; they work closely together and know all about each other's specialties and whereabouts. [...] The same thing, we knew, would be true of the Germans.

[pp. 31–33]: There are still a few secrets which members of the Mission are not supposed to reveal. We are not supposed to tell just who among the Army personnel were directly connected with the A-bomb Intelligence. We cannot divulge how much uranium and heavy water was found in Germany and what was done with it. We helped find it, but never knew how much it was until later press dispatches from Germany told us about it. [...]

To an outsider, a professor is a professor, but we knew that no one but Professor Heisenberg could be the brains of a German uranium project and every physicist throughout the world knew that.

There are people who ask us every so often, whether we are absolutely sure we now know everything the Germans did. How can we be sure that somewhere in Germany, still hidden, there isn't a group of men, whom we have never heard of, secretly manufacturing atom bombs even now. There were even Intelligence reports referring to such a possibility. During the time the Russians occupied the Danish island of Bornholm, one heard frequent official and unofficial rumors to the effect that there was a group of German scientists on the island who had completed an atom bomb. We came across similar rumors frequently during our investigations.

I still do not know how to explain the absurdity of these rumors and how to convince non-scientists. Possibly a paper hanger can become a military expert, and a wine merchant a diplomat; but an outsider simply can't acquire the necessary scientific knowledge for making an atom bomb overnight. We are always told, with some exaggeration, that only a dozen people in the world understand Einstein. It follows that at least one of that dozen must be included in any atom bomb project since its construction is so closely tied up with Einstein's theory! In other words, we knew who our chief targets were in Germany before we started. What we had to find out was how far they had advanced on their atom bomb project.

[pp. 80–83]: The director at that Medical Institute was the famous organic chemist, Richard Kuhn. When the chemists with our Mission, Professors Louis Fieser of Harvard and Carl Baumann of Wisconsin, met him, Kuhn was most co-operative. They had known him before and he welcomed them back in his laboratory. He told them that he had no connection with war work, but that it was all directed by the chemist Thiessen in Berlin. He had no secret reports and had merely worked on the chemistry of modern drugs. [...]

Richard Kuhn's record did not seem too clean to me. As president of the German Chemical Society he had followed the Nazi cult and rites quite faithfully. [...] I could not believe that he was not familiar with important war work, although I had no time to look into this matter further. We knew, however, that he had been one of the administration bosses of German war chemistry, and later in Berlin Baumann discovered some valuable secret reports on applied chemistry which were no doubt familiar to Kuhn. Back in Heidelberg we had him picked up by one of our officers.

I showed him the secret reports, and reproached him for not having told us about them half a year earlier, when he knew all the time what we were after and when he acted as if he were co-operating with us. [...]

It was quite important. It contained articles on industrially valuable applications of chemistry, such as the production of plastics, asbestos, the use of coal tar, aluminum, cellulose, sulfur, etc. This rare set of documents is now in the possession of the American Chemical Society, and I am still sore for allowing myself to be fooled by Herr Kuhn. We could have got these documents in April instead of September.

[pp. 112]: A few days afterward Munich fell. Here Carl Baumann, accompanied by a few officers and men, located Walther Gerlach, who had been in charge of nuclear research and all physics research for the last year. He also discovered Diebner and the uranium, which the Gestapo had taken from the secret laboratory in Thüringen, and brought back more interesting documents.

[pp. 121–122]: [Gerlach's] only wish was to save and to promote German physics without the help or obstruction of the Nazis. [...] But it was all too late. The war was over before Gerlach's influence took hold.

We could get nothing out of Diebner. He was as sullen as a real prisoner. He must have felt like an outcast, living in the same house with members of the Heisenberg clique. Their conversations with him were limited to monosyllables.

[pp. 123–126]: It was not until late in July that a small Alsos group was allowed to enter Berlin. As we expected, we found no new information but what we learned was very satisfying. It was like the last pieces of a jigsaw puzzle; the pieces of haphazard information we gathered completed the picture, plugged up a few minor holes, but the pattern remained the same.

We found, for instance, the chief chemist of the Auer Chemical Company, for whom we had been looking ever since we had entered Belgium. But he could tell us nothing we did not already know, nor could the few industrial physicists who still remained in Berlin. The Gestapo scientists had all cleared out before our arrival, some of them leaving sufficient clues in their deserted homes for us to track them down later. [...]

Our chief visit was, of course, to the now empty Kaiser Wilhelm Institute for Physics, where the uranium research had started in 1939. [...] We went in and found one room furnished with two desks and one officer. [...] He did not understand our interest in this building.

"It's all empty," he said. "Everything, even switches and wiring, has been removed by the Russians. We found some junk which we dumped in the back yard." [...]

We inspected the place thoroughly. The backyard "junk" contained various pieces of equipment for nuclear physics as well as blocks of pressed uranium oxide. There were also some notebooks indicating the type of research that had been going on.

[pp. 142–145]: Army research was conducted by the Ordnance Department headed by the mediocre physicist, Erich Schumann. Professor Schumann's right hand man was Diebner. [...]

Schumann was actually professor of military physics at the University of Berlin, although his few publications deal only with the vibrations of piano strings—an interest derived, presumably, from the fact that he was a descendant of the composer, Schumann.[...]

In Schumann's case, the work had been shrouded in secrecy even before the war, and so no one knew quite what was going on in the Second Institute, although the first rate physicists knew, from the type of personnel he was using, it could not be very important or successful. [...]

But the uranium problem is rather more difficult than the mysteries of piano strings and Schumann became impatient. By the end of 1942 he had lost interest in the project; he turned Diebner, personnel, equipment and material over to the civilian research organization, the Reich's Research Council, which had just been placed under Goering. He did not, however, turn over the two million marks his research group had been granted by the Army.

Schumann next devoted his talents to bacterial warfare. It is probable that in this field his competence was even less than in physics and its wartime applications. But he liked to be involved in things that looked important and his name shows up on many rosters of research committees.

When Berlin fell, Schumann fled to Bavaria. The Alsos Mission followed his trail for a short while, mainly out of curiousity, but we soon gave up. He was so obviously unimportant.

[pp. 160, 164–166]: As scientific adviser to Army Ordnance, Professor Schumann made immediate preparations for secret research into the uranium problem with a view to producing the super-explosive. But he himself was only a second-rate physicist, and his helpers were not much better. [...]

What made this even more irritating was that the academic scientists considered Schumann and his group far below their level. They thought it outrageous that such men should be given so much power, and felt certain that they would never succeed in their researches. [...]

Von Ardenne was not a physicist in the German academic sense, but he was a first-rate experimenter; a designer and builder of important laboratory apparatus, and a successful business man. He found out that the Postal Department had a research section with a large budget that was not being used. Contacting Ohnesorge, the gullible Postal Minister, he told him all about the wonders of atomic power and explosives.

And so it came about that Von Ardenne's Berlin laboratory was made a branch of Postal Research, and Ohnesorge, at a cabinet meeting, informed Hitler about the uranium bomb. [...]

For a time the technician Baron Manfred von Ardenne was the official expert on nuclear physics to the Nazi government. Even today the academic physicists refer to this as one of the severest insults they ever received from the government, and the reason for some of them becoming anti-Nazi. "If only the government had taken the true scientists into its confidence instead of those charlatans like Von Ardenne and Schumann," they complained to us on the Alsos Mission. [...]

The real brains of the project was Werner Heisenberg.

[pp. 176–177]: They knew, of course, of the possibility of a U-235 bomb, but they considered it practically impossible to separate pure U-235. One can hardly blame them for this. Perhaps only in America could one have visualized and realized an Oak Ridge, where pure U-235 was produced by the huge combined efforts of science, engineering, industry, and the Army. No such vision was apparent among the German scientists and certainly no such gigantic combination of all forces working on all cylinders.

Furthermore, the Germans never thought of using plutonium in the bomb, which enormously simplified the problem. The existence and probable properties of plutonium, though still unnamed, had been mentioned in scientific literature before the war, and in a few German secret reports, but they overlooked the practical phase of this side of the problem completely.

In fact, the whole German idea of the bomb was quite different from ours and more primitive in its conception. They thought that it might eventually be possible to construct a pile in which the chain reaction went so fast that it would produce an explosion. Their bomb, that is, was merely an explosive pile and would have proved a fizz compared to the real bomb.

[pp. 201–202:] During the war the SS had a few technical research laboratories of its own, under the direction of an SS-General Schwab, but these did not amount to anything. They tried some work on heavy water, but soon gave up and sent their "expert" on this subject to the University of Hamburg to continue his work with the legitimate physicists.

The principal "scientific" interest of the SS was ancient Germanic history, with a view to proving the greatness of their Teutonic ancestry. It was for this purpose that Himmler created his own "scientific academy" in 1935, Das Ahnenerbe, or Academy of Ancestral Heritage. Because some of the activities of this strange academy were shrouded in mystery that might just possibly have concealed something really important, we assigned Carl Baumann to make a thorough investigation of the organization for Alsos.

Except for Himmler's letter to hangman Heydrich about the physicist Heisenberg, [...] Baumann did not discover anything connected with atomic research in the Ahnenerbe material. [...]

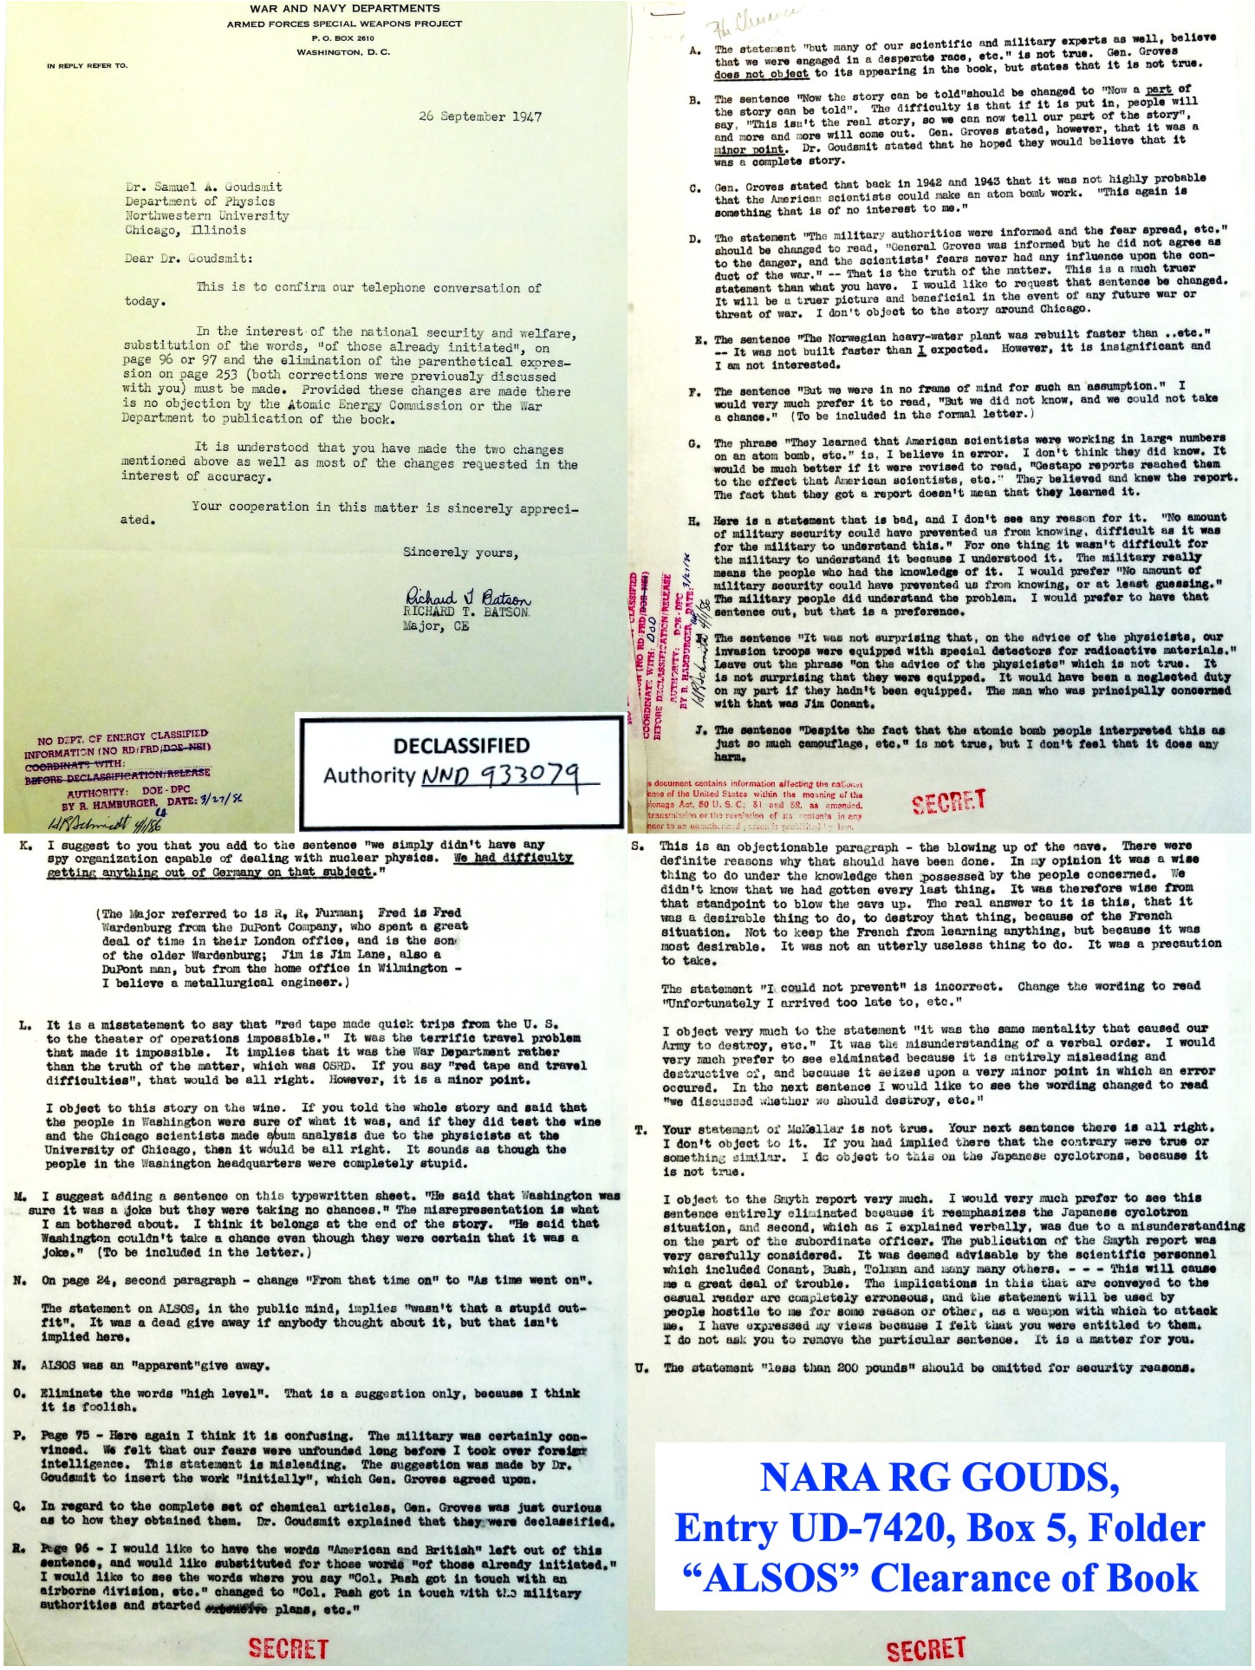
[In his 1947 book, Samuel Goudsmit repeated the erroneous claims he had made when he knowingly gave false testimony to the United States Senate in December 1945 (pp. 3297–3305). Goudsmit would have been well aware that his claims were false based on documents from Alsos's own files, including but not limited to those listed on p. 3298.

In this book publicly praising his own performance, Goudsmit also conveniently failed to include many details such as those listed on p. 3307.

Due to censorship in 1947, Goudsmit could only refer to Major Robert Furman as the "Mysterious Major," and he could not mention the specific quantities of uranium that had been found. In their books written much later, in the 1960s, Groves and Pash were able to mention the name of Robert Furman and the specific quantities of uranium.

Even as Goudsmit complained about the "absurdity" of people asking him if he might have overlooked any German scientists who could build atomic bombs, in 1947 there were literally hundreds of German scientists whom Goudsmit had overlooked and who were developing the Soviet Union's first atomic bombs.

Goudsmit's opinion that (unlike America) Germany was incapable of "huge combined efforts of science, engineering, industry, and the Army" is clearly contradicted by a number of massive and very successful German programs that involved all of those sectors: the missile programs, the nerve gas program, the jet programs, programs that developed and mass-produced synthetic fuels and rubber, and many others. In fact, whereas the United States was still very new to that sort of approach, it had been the foundation of German research and development for many decades.]



WAR AND NAVY DEPARTMENTS
ARMED FORCES SPECIAL WEAPONS PROJECT
P. O. BOX 2610
WASHINGTON, D. C.

IN REPLY REFER TO.

26 September 1947

Dr. Samuel A. Goudsmit
Department of Physics
Northwestern University
Chicago, Illinois

Dear Dr. Goudsmit:

This is to confirm our telephone conversation of today.

In the interest of the national security and welfare, substitution of the words, "of those already initiated", on page 96 or 97 and the elimination of the parenthetical expression on page 253 (both corrections were previously discussed with you) must be made. Provided these changes are made there is no objection by the Atomic Energy Commission or the War Department to publication of the book.

It is understood that you have made the two changes mentioned above as well as most of the changes requested in the interest of accuracy.

Your cooperation in this matter is sincerely appreciated.

Sincerely yours,

Richard T. Batson
RICHARD T. BATSON.

The Clearance

A. The statement "but many of our scientific and military experts as well, believe that we were engaged in a desperate race, etc." is not true. Gen. Groves does not object to its appearing in the book, but states that it is not true.

B. The sentence "Now the story can be told"should be changed to "Now a part of the story can be told". The difficulty is that if it is put in, people will say, "This isn't the real story, so we can now tell our part of the story", and more and more will come out. Gen. Groves stated, however, that it was a minor point. Dr. Goudsmit stated that he hoped they would believe that it was a complete story.

C. Gen. Groves stated that back in 1942 and 1943 that it was not highly probable that the American scientists could make an atom bomb work. "This again is something that is of no interest to me."

D. The statement "The military authorities were informed and the fear spread, etc." should be changed to read, "General Groves was informed but he did not agree as to the danger, and the scientists' fears never had any influence upon the conduct of the war." -- That is the truth of the matter. This is a much truer statement than what you have. I would like to request that sentence be changed. It will be a truer picture and beneficial in the event of any future war or threat of war. I don't object to the story around Chicago.

E. The sentence "The Norwegian heavy-water plant was rebuilt faster than ..etc." -- It was not built faster than I expected. However, it is insignificant and I am not interested.

F. The sentence "But we were in no frame of mind for such an assumption." I would very much prefer it to read, "But we did not know, and we could not take a chance." (To be included in the formal letter.)

G. The phrase "They learned that American scientists were working in large numbers on an atom bomb, etc." is, I believe in error. I don't think they did know. It would be much better if it were revised to read, "Gestapo reports reached them to the effect that American scientists, etc." They believed and knew the report. The fact that they got a report doesn't mean that they learned it.

H. Here is a statement that is bad, and I don't see any reason for it. "No amount of military security could have prevented us from knowing, difficult as it was for the military to understand this." For one thing it wasn't difficult for the military to understand it because I understood it. The military really means the people who had the knowledge of it. I would prefer "No amount of military security could have prevented us from knowing, or at least guessing." The military people did understand the problem. I would prefer to have that sentence out, but that is a preference.

I. The sentence "It was not surprising that, on the advice of the physicists, our invasion troops were equipped with special detectors for radioactive materials." Leave out the phrase "on the advice of the physicists" which is not true. It is not surprising that they were equipped. It would have been a neglected duty on my part if they hadn't been equipped. The man who was principally concerned with that was Jim Conant.

J. The sentence "Despite the fact that the atomic bomb people interpreted this as just so much camouflage, etc." is not true, but I don't feel that it does any harm.

SECRET

K. I suggest to you that you add to the sentence "we simply didn't have any spy organization capable of dealing with nuclear physics. We had difficulty getting anything out of Germany on that subject."

(The Major referred to is R, R, Furman; Fred is Fred Wardenburg from the DuPont Company, who spent a great deal of time in their London office, and is the son of the older Wardenburg; Jim is Jim Lane, also a DuPont man, but from the home office in Wilmington - I believe a metallurgical engineer.)

L. It is a misstatement to say that "red tape made quick trips from the U. S. to the theater of operations impossible." It was the terrific travel problem that made it impossible. It implies that it was the War Department rather than the truth of the matter, which was OSRD. If you say "red tape and travel difficulties", that would be all right. However, it is a minor point.

I object to this story on the wine. If you told the whole story and said that the people in Washington were sure of what it was, and if they did test the wine and the Chicago scientists made sbum analysis due to the physicists at the University of Chicago, then it would be all right. It sounds as though the people in the Washington headquarters were completely stupid.

M. I suggest adding a sentence on this typewritten sheet. "He said that Washington was sure it was a joke but they were taking no chances." The misrepresentation is what I am bothered about. I think it belongs at the end of the story. "He said that Washington couldn't take a chance even though they were certain that it was a joke." (To be included in the letter.)

N. On page 24, second paragraph - change "From that time on" to "As time went on".

The statement on ALSOS, in the public mind, implies "wasn't that a stupid outfit". It was a dead give away if anybody thought about it, but that isn't implied here.

N. ALSOS was an "apparent"give away.

O. Eliminate the words "high level". That is a suggestion only, because I think it is foolish.

P. Page 75 - Here again I think it is confusing. The military was certainly convinced. We felt that our fears were unfounded long before I took over foreign intelligence. This statement is misleading. The suggestion was made by Dr. Goudsmit to insert the work "initially", which Gen. Groves agreed upon.

Q. In regard to the complete set of chemical articles, Gen. Groves was just curious as to how they obtained them. Dr. Goudsmit explained that they were declassified.

R. Page 96 - I would like to have the words "American and British" left out of this sentence, and would like substituted for those words "of those already initiated." I would like to see the words where you say "Col. Pash got in touch with an airborne division, etc." changed to "Col. Pash got in touch with the military authorities and started ~~extensive~~ plans, etc."

SECRET

S. This is an objectionable paragraph - the blowing up of the cave. There were definite reasons why that should have been done. In my opinion it was a wise thing to do under the knowledge then possessed by the people concerned. We didn't know that we had gotten every last thing. It was therefore wise from that standpoint to blow the cave up. The real answer to it is this, that it was a desirable thing to do, to destroy that thing, because of the French situation. Not to keep the French from learning anything, but because it was most desirable. It was not an utterly useless thing to do. It was a precaution to take.

The statement "I could not prevent" is incorrect. Change the wording to read "Unfortunately I arrived too late to, etc."

I object very much to the statement "it was the same mentality that caused our Army to destroy, etc." It was the misunderstanding of a verbal order. I would very much prefer to see eliminated because it is entirely misleading and destructive of, and because it seizes upon a very minor point in which an error occured. In the next sentence I would like to see the wording changed to read "we discussed whether we should destroy, etc."

T. Your statement of McKellar is not true. Your next sentence there is all right. I don't object to it. If you had implied there that the contrary were true or something similar. I do object to this on the Japanese cyclotrons, because it is not true.

I object to the Smyth report very much. I would very much prefer to see this sentence entirely eliminated because it reemphasizes the Japanese cyclotron situation, and second, which as I explained verbally, was due to a misunderstanding on the part of the subordinate officer. The publication of the Smyth report was very carefully considered. It was deemed advisable by the scientific personnel which included Conant, Bush, Tolman and many many others. - - - This will cause me a great deal of trouble. The implications in this that are conveyed to the casual reader are completely erroneous, and the statement will be used by people hostile to me for some reason or other, as a weapon with which to attack me. I have expressed my views because I felt that you were entitled to them. I do not ask you to remove the particular sentence. It is a matter for you.

U. The statement "less than 200 pounds" should be omitted for security reasons.

NARA RG GOUDS,
Entry UD-7420, Box 5, Folder
"ALSOS" Clearance of Book

SECRET

Figure D.40: Example of U.S. government censorship of Samuel Goudsmit's 1947 book, *Alsos* [NARA RG GOUDS, Entry UD-7420, Box 5, Folder "ALSOS" Clearance of Book]. "The sentence 'Now the story can be told' should be changed to 'Now a part of the story can be told'. The difficulty is that if it is put in, people will say, 'This isn't the real story, so we can now tell our part of the story', and more and more will come out... Dr. Goudsmit stated that he hoped they would believe that it was a complete story."

Boris T. Pash. 1969. *The Alsos Mission.* New York: Award House.

[pp. 156–158:] Our scientists soon joined us in Strasbourg. Bob Furman and Lt. Tony Biot, a Navy physicist, had already arrived. Sam Goudsmit and Fred Wardenberg reported two days later.

[...] Our scientific sleuths were more than usually agitated by the material probed although they would be the last to admit it. After a while, I heard Sam Goudsmit exclaim, “We’ve got it!”

“I know we have it,” I remarked. “But do they?”

The two scientists were the only ones who knew to what I was referring. They smiled, and Sam Goudsmit’s eyes were wide with excitement.

“No, no!” he said. “That’s it. They don’t!” The scientists remained up far into the night, poring over the papers. [...]

Interrogation of the captured scientists, study of the seized documents and inspection of the laboratories took several days. But the two days during which Sam Goudsmit, Fred Wardenberg and Bob Furman worked on our priority interest were as important to our top leaders and to the British as any other phase of the war. It was our Strasbourg operation which disclosed that it was unlikely that the Nazi could unleash an atom bomb in the near future.

Thus Alsos exploded the Nazi super-weapon myth that had so alarmed Allied leaders. The fact that a German atom bomb was not an immediate threat was probably the most significant single piece of military intelligence developed throughout the war. Alone, that information was enough to fully justify Alsos. [...]

[p. 162, early December 1944:] But in Paris I learned there was to be no rest for any of us. It was my turn to be called back to Washington, Sam Goudsmit having already preceded me there. He had left without designating a replacement for himself. Fortunately, among the scientists who had joined us for the Strasbourg operation was Dr. Henry Reid, an able and pleasant engineer.

After a conference with Commodore Schade, I asked Reid to assume the duties of Deputy Scientific Chief. This proved a good move. Henry’s organizational and administrative skills were to be of great value to us during the winter of 1944–45 when the unit was rapidly expanding.

In Washington, the status of our scientists and their activities were the primary concern, formally and informally. While no one made any comments which could imply criticism, it was evident that some rumblings from the field might not have been complimentary.

Sam and I soon cleared the air. Even those previously hostile were mollified by our reports. [...]

[pp. 216–218:] In Hechingen, the entire Alsos scientific contingent was interrogating the German scientists and trying to locate significant lab reports and documents. [...]

Upon our return we learned that the secreted uranium of the Haigerloch pile, as well as the supply of heavy water, was buried near an old water-drive grist mill outside town. [...]

The 1269th provided trucks that hauled the uranium and heavy water, along with recovered graphite, to SHAEF Scientific Section for transhipment to the United States.

Thus ended Operation Big.

With the exception of Doctors Heisenberg, Gerlach and Diebner [who were found shortly later], Alsos had taken into custody every German scientist whose name appeared on the "wanted" list.

And the German atomic pile, with all related equipment and documents, were in American hands.

Upon receiving my report that "Alsos has hit the jackpot," General Harrison immediately sent a message to General Devers stating, "Boris Pash has hit the jackpot." [See p. 3323.]

[Pash confirmed that the scientific conclusions of Alsos were dominated by Goudsmit, that those conclusions were reached in Strasbourg in November 1944 (long before visiting most of the areas and scientists involved in the nuclear program), that Alsos was only interested in a few famous scientists on their short predetermined list, and that they were satisfied they were finished once they found the Haigerloch fission pile.

Pash also confirmed that Goudsmit had been suddenly relieved of duty in early December 1944 and sent back to the United States. Pash added that he himself had also been sent back to the United States, and that both he and Goudsmit had then had to answer criticisms of their performance in high-level meetings in Washington. Although Pash did not specify the criticisms, they must have been quite serious to warrant such actions in the middle of the war when Alsos personnel were urgently needed in Europe.]

Figure D.41: “For the Eyes Only of General Marshall and the Secretary of War from Eisenhower... have secured personnel, information and materiel exceeding their wildest expectations” [Pash 1969, frontispiece; also NARA RG 77, Entry UD-22A, Box 160, Folder APR 45–Dec. ’45].

***Manhattan District History*, Book I, Volume 14, Foreign Intelligence Supplement No. 1. Undated but apparently ∼1947.**
[**https://ia803409.us.archive.org/14/items/ManhattanDistrictHistory/**]

[Some original Alsos documents are reproduced near the end of this file, with varying degrees of legibility. Why are nearly all of the references in this file redacted, when nothing else seems to be?]

4-1. General.

[...] Lt. Col. Boris T. Pash and Dr. Samuel A. Goudsmit had respectively been appointed Mission Chief and Scientific Chief.

[...] Based on preliminary lists from the United States, much of the early definition of German intelligence targets was accomplished at the London headquarters with the assistance of British technical and intelligence personnel. Priorities were assigned to locations and personnel, and while later events proved some of the investigations to be unproductive, no important elements were missed as far as the interest in atomic energy was concerned. [...]

4-2. Paris Operations.

[...] Advance personnel of the ALSOS Mission entered Paris on August 1944, with leading elements of the Allied troops, and promptly secured initial targets. [...] Joliot [...] added very little to the knowledge already possessed by the Manhattan Project; however, the following items were clarified:

(1) The College de France (Joliot's laboratory) cyclotron had remained in service at that institution, although, at one time, the enemy had given some consideration to transporting it into Germany

(2) Schumann, Diebner, Bothe, Esau, Gentner, Bagge, and Maurer, all enemy personnel of interest to the Manhattan Project, had spent varying lengths of time during the war at the College de France laboratory, concerning themselves with the cyclotron operation. [...]

[...] ALSOS Mission reached Brussels, Belgium, on 5 September 1944. A Mr. Gaston André, in charge of uranium, at the main office of the Union Minière du Haut Katanga, was contacted. [...]

(1) Prior to the war a number of German firms had received uranium products from Belgium for normal peacetime application or retrade. The shipments had, in general, consisted of quantities of less than one ton per month of assorted refined materia.

(2) From June, 1940, until August, 1941, the Auer Gesellschaft, a well-known German chemical concern, which had not been a recipient prior to the war, suddenly became an outstanding consumer of uranium products. Auer received about 60 tons of refined material during that period. It was learned that a Dr. Ihwe was apparently in charge of purchases for the Auer company.

(3) The next large German shipment of interest was in November, 1941, and consisted of about nine tons of uranium products to [...] Degussa. [...]

(4) During June, 1942, unusually large amounts of uranium products were sent to "Roges, m.b.H". [...] Within this organization a Dr. Faust was in charge of uranium ores. The amounts of uranium products ordered by Roges consisted of about 115 tons of assorted refined and half refined materials. In addition they obtained 610 tons of crude material, 17 tons of ferro-uranium, and about 110 tons of impure products (rejects). Also, in January and May, 1943, respectively, 50 tons and 80 tons of refined products were delivered to them.

[...] During the preceding investigation at Brussels, a preliminary study of uranium stock, by the Union Minière du Haut Katanga, indicated that a quantity of material remained in Belgium. [...] The captured material, amounting to 68 tons, was placed under joint American and British control and removed from Belgium.

[...I]t was learned that nine carloads of uranium (approximate total net weight 72 tons) had been shipped, in advance of the German invasion, from Hoboken, Belgium to le Havre, France, in May, 1940. Reports indicated subsequent German seizure, at le Havre, of two of the nine carloads and the movement of the remainder to Bordeaux. [...] 30 tons of the reported material was found at the Poudrerie de Toulouse, in Toulouse. This material was secured and shipped from Marseilles to the United States. Investigation continued for the remaining 42 tons, but that particular search was not successful. [...]

4-3. Strasbourg Operation.

On 25 November 1944, advance military members of the ALSOS Mission joined the T-Force in Strasbourg.

[...] Concerning the interest of the Manhattan Project, four of the academic personal targets—Rudolf Fleischmann, Head of the Physics Department; Fritz Weygand, Head of the Chemistry Department; Hugo Neuert, Experimental Physicist; and Werner Maurer, Experimental Physicist, had such backgrounds and occupations as to warrant their separation from other internees and transfer, at a later date, to the United States. [...] Field interrogation of these individuals failed to confirm that any of them had engaged in direct research on a nuclear weapon, and their replies to repeated questioning actually provided little worth-while information. [...] In contrast to the meager information obtained from personal targets, the written matter located at Strasbourg served as a source of outstanding intelligence. [...] While the information was unclassified, through the mediums of notes of meetings, fragments of computations, protocols of experiments and vague hints in personal correspondence, a revealing picture of the German nuclear research program was presented.

[...] That evidence in a great measure modified the fear of enemy competition with the Manhattan Project, but it was still believed to be highly essential that those encouraging indications be confirmed beyond all possible doubt. [...] All of the foregoing information, after being subjected to an analysis by both the Manhattan District and the OSRD, resulted in a comprehensive report “TA Targets–German” [...] which served as a dependable guide for subsequent exploitation.

4-4. Heidelberg Operation.

[...] Professor Walther Bothe, Director, Physics Division of KWI for Medical Research, Heidelberg, was interrogated on 30 and 31 March [...]

(1) It was confirmed that Hahn had been evacuated to Tailfingen, and that Heisenberg and von Laue were at Hechingen.

(2) The installation, including the experimental uranium pile which was at Berlin-Gottow, had been removed to Haigerloch.

(3) A German shortage of heavy water was reported, and reference was made to the only production having been that in Norway.

(4) Professor Bothe listed the following as having worked on the nuclear physics phase of the uranium problem.

- (a) Himself, with three helpers
- (b) Heisenberg, with ten men
- (c) Döpel, in Leipzig, assisted by his wife only
- (d) Kirchner, in Garmisch, with possibly two men
- (e) Stetter, in Vienna, with four or five men

(5) Approval of Gerlach was required for physicists to secure means for scientific work, and if a “DE” (highest) priority was desired the additional approval of [Albert] Speer, Minister of War Production, had to be obtained.

(6) Bothe expressed his opinion that the separation of uranium isotopes by the thermal diffusion method was impossible. He indicated that the only work on isotope separation in Germany was being done by the centrifugal method under the direction of Harteck. Bothe was not aware of the location of this activity.

(7) Bothe believed that uranium hexafluoride was made by I.G. Farben, at Leverkusen.

(8) Bothe stated that no element higher than 93 was definitely known; however, he recognized that, as element 93 was a beta emitter, 94 must exist.

(9) Bothe repeatedly expressed his opinion that the uranium pile, as a source of energy, was decades from realization and that the use of uranium as an explosive was impracticable. He claimed not to know of any theoretical or experimental work being done in Germany on the military application of nuclear fission; but indicated that such work could be under way without his knowledge.

(10) After repeated questioning concerning the military value of the cyclotron, Bothe said it had been considered as a means of obtaining radioactive material for bombs.

(11) All secret documents in connection with his work were reported by Bothe to have been burned in accordance with government instructions.

[...] Dr. Wolfgang Gentner was interrogated on 1 April and, in general, confirmed the information given by Bothe. [...]

4-5. Frankfurt Operation.

On 31 March and 1 April, 1945, several of the Degussa plants were contacted and a number of the employees were interviewed. It was confirmed that Degussa had produced uranium metal under the name of “Spezialmetall”; however, personnel investigated professed indefinite knowledge concerning the use of the metal and the ultimate destinations to which it was shipped.

[...] Dr. Kohl, Works Manager, Degussa Plant No. 2, was interrogated on 3 April 1945, concerning the manufacture of “Spezialmetall”. According to him the material was required by the Reich’s Research Council (RFR) and all administrative matters were handled directly with RFR by Auer, in Oranienburg. Degussa acted as a sub-contractor for Auer and Kohl understood that deliveries of metal were made either to Auer or to the RFR, at Berlin-Dahlem. The use of the metal was secret, but Kohl believed it to be concerned with experiments in atomic physics. He stated that the material was manufactured, to a purity of 98 to 99 percent, from ammonium uranate which was converted to U_3O_8. The ammonium uranate was secured either from Joachimstahl or the Union Minière du Haut Katanga. Kohl referred to an early process where metallic uranium had been mixed with coal dust, with Tragacanth gum as a binding material, and pressed into blocks. The material was later delivered as powdered metallic uranium, production being between one and two tons. Kohl was emphatic that no deliveries of uranium were made to I. G. Farben Industrie. The Degussa plant, at Frankfurt, had been partially destroyed and parts of the equipment were reported to have initially been moved to a location in Mark Brandenburg, and later to the plant of the Chemische Fabrik Grünau at Berlin-Grünau. Approximately three tons of ammonium uranate were shipped with the equipment to Berlin-Grünau. It was reported that, prior to the war, about three tons per month of sodium uranate were used in the ceramic color business but that during the war such use had been prohibited.

[...] Dr. Baerwind, director of Degussa in charge of technical matters, was also interrogated at Frankfurt, on 3 April. Subject to the following comments Baerwind's statements in general confirmed those previously made by Kohl.

(1) While Baerwind was then a member of the Supervisory Board of Auer, nevertheless he was not familiar with the dealings between Auer and the nuclear scientists.

(2) Baerwind indicated his unfamiliarity with the technical details, and expressed his opinion that Kohl might also have been uninformed; however, he stated definitively that the uranium powder was not mixed with coal dust.

(3) Reference was made to Degussa production of from five to six tons per year of beryllium metal. Most of this material was reported to have been sent to Heraeus, for the manufacture of beryllium copper alloys, but a small amount had been sent to the RFR for experiments with radioactive materials.

(4) Baerwind believed that the "Spezialmetall", even under the secret handling, could have nothing to do with military weapons because the quantities involved were so small. He stated definitively that Degussa was the only manufacturer of uranium metal in Germany and that until 1944 the Frankfurt plant production constituted all of the Degussa production.

[...] In September, 1945, an account of the production of uranium metal by Degussa was obtained by the ALSOS Mission. This account was prepared by a Degussa employee (Völkel [...]) and presented production and shipping details as well as a description of the process employed. It revealed that the Frankfurt Plant No. 2 had handled about 12,8000 kg. of the material from 1940 to 1945. [...] The progress of the war had caused manufacture of uranium metal to be transferred from the Degussa, Frankfurt, plant to a factory at Berlin-Grünau. Production at Grünau started at the end of 1944. It was indicated that "Spezialmetall" had only been manufactured in quantities suitable for experimental purposes and that the purity of the product was not impressively high.

[...] The ALSOS Mission had learned that 11 tons of crude sodium uranate had been delivered to the Radium Chemie Companie, of Frankfurt, from Wirtschaftliche Forschungsgesellschaft, in July, 1943, and that information prompted a contact with the Frankfurt firm on 25 April, 1945. [...] Through questioning the Deputy Director of the firm it was learned that a stock of 11 tons of uranium products, ½ ton of Schmiedberg ore and a few drums of monazite sand were on hand. That material was confiscated. In addition to the material obtained, this operation proved to be of interest in providing evidence that the Joachimstahl mines were being worked and that the shortage of radium in Germany made it worth while to exploit the Schmiedeberg deposits. [...]

4-6. Stadtilm Operation.

[...] ALSOS team arrived at Stadtilm, Thuringen, on 12 April 1945, directly after fighting in the town had ceased. The laboratory and offices of Dr. Kurt Diebner were located in an old schoolhouse. It was found that the majority of the target personnel, together with their documents, materials and equipment, had been evacuated by the Gestapo, on 8 April, in order that they might carry on their work elsewhere. However, the following individuals, of interest to the ALSOS Mission, had been allowed to remain at Stadtilm: Hartwig, Physicist; Ebeling, Mechanic; Leimert, Librarian; Stuhlinger, Physicist; Pfetscher, Physicist; Berkei, Physicist; Ehlert, Office Manager; Seeger, Engineer; and Schutzmeister, Physicist.

[...] Gerlach was a frequent visitor at Stadtilm.

[...] The physics institute of the KWI and of the THS [Technische Hochschule] Berlin had been partially evacuated to Stadtilm about 6 months previously but, for some unknown reason, a number of the personnel had been extremely slow in the relocation.

[...] Documents, materials and equipment at Stadtilm consisted of: many files; 8 tons of uranium oxide; parts of a small low temperature pile; air liquefaction apparatus; heavy water equipment from Norway; counters; miscellaneous equipment; and an extensive physics laboratory.

For about four years [Dr. Berkei] had worked for the KWI for Physics, at Berlin-Dahlem and Berlin-Gottow, and later served as administrative assistant to Diebner. While, in his administrative capacity, he had not had the opportunity to learn of many of the technical details, nevertheless Berkei appeared to have a good overall picture of Diebner's work...

4-7. Göttingen Operation.

The subject of interest to the Manhattan Project was discussed with Professors Kopfermann and Houtermans, at Göttingen, on 17 April 1945. [...] Kopfermann and Houtermans had been only on the fringe of the German nuclear fission project and were unable to contribute additional intelligence of any particular consequence. [...]

4-8. Lindau Operation.

[...] Osenberg surrendered with some ceremony, making his personnel, files and the general establishment available for investigation. ALSOS scientific members began their examination of the Planning Board on the afternoon of 12 April, and continued with the interrogation of Osenberg, questioning of his personnel and study of his papers during the following three days. [...]

4-9. Celle Operation.

[...] Those Mission members entered Celle on 17 April and readily located the centrifuge laboratory. That laboratory was found to be under British guard. [...]

(1) The ultra-centrifuge experments, evacuated the preceding November from Hannover, were located within a spinning mill at Celle.

(2) The director of the activity, Harteck, was not present and was reported to be at Hamburg. Dr.

W. Groth was in charge of the Celle laboratory, together with Dr. Suhr and Dr. Faltings.

(3) The equipment consisted of a small-scale set-up. When working smoothly it was estimated to be capable of a production of 50 grams per day of enriched material. The enrichment was at best about 15 percent.

(4) The separation was done with gaseous UF_6. Groth discovered that it was possible to produce the gas directly from the oxide, without having to make metal first. This method had been patented by him, and the material was produced by I. G. Farben, at Leverkusen, in quantities of about 30 pounds per month.

(5) The oil used in the centrifuge contained powered sodium fluoride in suspension so as to saturate against the effect of UF_6.

(6) The centrifuge was manufactured by Anschütz Gesellschaft at Kiel.

(7) In general, the net result of the investigation was that it confirmed former investigations in revealing the nuclear energy effort in Germany to be on a relatively small scale.

4-10. Stassfurt Operation.

The ALSOS Mission investigation at Brussels, Belgium, in September 1944, revealed that certain quantities of Belgian uranium products had been removed to Germany. [...] Based upon that intelligence a considerable portion of the material was believed to have been delivered to a plant of the Wirtschaftliche Forschungsgesellschaft (WIFO), on the outskirts of Leopoldshall, near Stassfurt. That firm had been formed during the war as a storage agency for Roges. [...]

Removal of 260 truck loads of the material to the Hildesheim Air Strip was accomplished between 20 and 27 April. The material seized consisted of crude sodium uranate, refined products and ferro-uranium. The total weight was in the neighborhood of 1,000 metric tons. It was held at Hildesheim until 30 April, moved to Antwerp and then shipped to a location under Allied control.

4-11. Caterode and Nordhausen Operations.

Fragmentary information suggested material possibilities at Caterode and Nordhausen and these targets were visited with negative or minor results.

4-12. Haigerloch, Hechingen, Bisingen, and Tailfingen Operations.

Scientific members of the ALSOS Mission left Heidelberg on 23 April and proceeded to Haigerloch where it was found that the targets had been secured and placed under guard. Those members of the Mission then went directly to Hechingen.

At Hechingen, the branch of the KWI for Physics was located and secured. Important personnel apprehended consisted of von Weizsäcker, Wirtz, von Laue, Moliere, Hoecker, Hiby, Sauerwein, Gysae, Bagge, Korsching, Bopp, Fischer and Menzer. [...] The enemy personnel at first stated that all secret documents had been burned in accordance with a government order, but, later following the capture of a complete set of secret reports at Tailfingen, and after demands had been made, von Weizsäcker admitted that certain reports had been concealed in a cesspool. Those reports were recovered. Two new isotope separation experiments of interest were in progress at Hechingen—Bagge's velocity selector, and Korsching's diffusion apparatus. The facilities for both of these experiments were dismantled and evacuated.

[...] The experimental pile [at Haigerloch...] had been located in a cave. The pile did not contain metal or heavy water. It was photographed, dismantled and the cave laboratory destroyed by explosives. Approximately one and one-half tons of heavy water and one and one-half tons of uranium metal were subsequently found buried near Haigerloch. This material was evacuated to a more secure location.

On 24 April, Bisingen was taken and a research station (Forschungsstelle D) of the Kaiser-Wilhelm Gesellschaft was secured. Dällenbach, the Director, had gone to Switzerland in December 1944 but his assistant, Dr. Karl Weimer, was interrogated. Construction of a small experimental model of a 10,000,000 volt cyclotron had been started, and drawings, technical data and patent specifications were secured.

Tailfingen was captured on 24 April, and, with it, headquarters of the KWI Für Chemie. All members of Hahn's staff including Hahn, Mattauch, Strassmann, Erbacher, Klemm, Flammersfeld, Radoch, Seelmann-Eggebert, Waldmann, Wietig and others were located. The three groups of the KWI Für Chemie at Tailfingen were led respectively by Hahn, Mattauch and Erbacher.

Professor Hahn's group had been working on the separation, distribution and energy of the fission products of uranium. According to him the results of that work had all been published, even though it was originally treated as secret. [...] He stated that the development of an atomic bomb was not then possible, and had so been considered by the Germans since 1942. Hahn did, however, believe that the pile as a source of energy would be successfully developed in a few years. [...]

Dr. Erbacher assisted in an inspection of his laboratory where work was being done on the chemical separation of isotopes; on the protection of uranium from corrosion, and on the separation of an active element from its inactive isotopes. [...]

Dr. Mattauch's laboratory was then inspected. Work was being performed at that location on the mass-spectrographic method of fission-product (or isotope) analysis. One member of Mattauch's group had been working on a method of isotope separation by the electrolysis of a fused salt; however, such a method had not at that time proved feasible.

From the Manhattan Project viewpoint the above operations were the most important of the ALSOS Mission investigations of the German effort in nuclear development. Interrogation of the enemy scientists, study of the documents obtained and inspection of the experimental equipment added further confirmation to previous evidence and definitely revealed the extremely small-scale activity of the whole German uranium project. In view of the fact that this exploitation involved the main group of laboratories it could be appreciated that the German work was far behind that which had been accomplished in the United States. [...]

4-13. Urfeld and Munich Operations.

[...] The advance to Urfeld was resumed and on 3 May the ALSOS group was successful in contacting Heisenberg. Heisenberg was taken to Heidelberg on the next day.

The second ALSOS team had entered Munich on 1 May 1945, and located the residence of Gerlach. Gerlach was not at home, but was found at the Physics Laboratory of the University of Munich. [...] On 2 May, a portion of the ALSOS group went to Schongeising, located their target and evacuated Diebner, certain of his documents, and a quantity of uranium (previously evacuated by the Gestapo from the laboratory at Stadtilm), to Munich. On 3 May, Gerlach and Diebner together with the captured material were transferred to Heidelberg.

Heisenberg, Gerlach and Diebner were interrogated upon their arrival at Heidelberg. As was expected, the interrogations failed to produce any new positive information of interest to the Manhattan Project.

[...] Gerlach was merely in administrative charge of the nuclear physics project. He had a superficial knowledge of the status of the project but knew little of the technical details.

[...] Diebner was not cooperative and seemed to be rather antagonistic toward Heisenberg. Gerlach and Heisenberg were on very cordial terms with each other but appeared to consider Diebner an inferior scientist.

4-14. Hamburg Operation.

After the City of Hamburg had fallen into Allied hands, members of the ALSOS Mission went to that location, on 5 May 1945, to contact Professor P. Harteck.

[...] Harteck's statement was to the effect that after the initial research it was soon discovered that the development of a weapon was unlikely, if not entirely impossible. Emphasis was then placed on the production of energy from a uranium pile, but, in this connection also, he was of the opinion that there were numerous detailed questions which had to be solved before such a device could be successful.

[...] Harteck referred to a plan which had been considered to provide ultra-centrifuge machines, each of which was to produce above 180 kgs. of 1 percent enriched material per year. The centrifuges were planned to be located at Kandern, but the progress of the war prevented the work.

[...] Harteck had studied the production of heavy water and believed that his improved method would have made it possible to reach a production of almost 10 tons per year, at an appreciable reduction in the pre-war cost. It was stated that the Norsk-Hydro project was under the supervision of I. G. Farben.

4-15. Berlin Operation.

The Berlin location of the Kaiser-Wilhelm Institute for Physics was inspected on 30 July 1945. It was found that practically all of the laboratory equipment had been evacuated by the Russians. [...]

4-16. Vienna Operation.

Dr. C. P. Smyth and other members of the ALSOS Mission visited Vienna during the later part of August, 1945, and obtained information of the research carried out at the Physical Institute and the Radium Institute. Information of uranium materials taken by Russian investigators in May, 1945, as well as of the transportation to Moscow of Drs. Wombacker and Ortner, was obtained. Little additional useful intelligence of the German uranium projected resulted.

4-17. Overall Results and Termination of Western and Central European Investigations.

a. The rapid advance of the Allies in Germany caused difficulty in making thorough and deliberate investigations of many of the detailed items of enemy nuclear research. Nevertheless, all principal locations of that research activity were contacted, and, as of May, 1945, the ALSOS Mission had apprehended the following German scientific personnel of interest to the Manhattan Project:

- At Strasbourg.
  - Fleischmann
  - Weygand
  - Neuert
  - Maurer

- At Heidelberg.
  - Bothe
  - Kuhn
  - Gentner

- At Hechingen.
  - von Weizsäcker
  - Wirtz
  - von Laue
  - Moliere
  - Hoecker
  - Hiby
  - Sauerwein
  - Gysae
  - Bagge
  - Korsching
  - Bopp
  - Fischer
  - Menzer

- At Bisingen.
  - Weimer

- At Hamburg.
  - Harteck

- At Marburg.
  - Justi

- At Stadtilm.
  - Hartwig
  - Berkei

- At Göttengen.
  - Houtermans
  - Kofpermann

- At Lindau
  - Osenberg

- At Celle.
  - Groth

- At Tailfingen.
  - Hahn
  - Mattauch
  - Strassmann
  - Erbacher
  - Klemm
  - Flammersfeld
  - Radoch
  - Seelmann-Eggebert
  - Waldmann
  - Wietig

- At Urfeld.
  - Heisenberg

- At Munich
  - Gerlach

- At Schongeising
  - Diebner

Early in the German endeavor the uranium problem had been separately approached by a number of more or less competing groups. There was one group under Army Ordnance, another under the Kaiser-Wilhelm Institute for Physics, and still another under the Postal Department. A certain amount of bickering over the supply of material and a non-cooperative attitude in the exchange of information existed between those groups. The research efforts of the Postal Department amounted to little and did not continue for very long. [...] Many German scientists worked along their own lines and were not required to work at particular projects. Development of an atomic weapon was not believed to be possible.

As a consequence of the foregoing, atomic energy development in Germany did not pass beyond the laboratory stage; utilization for power production rather than for an explosive was the principal consideration; and, though German science was interested in this new field, other scientific objectives received greater official attention.

***The History of the CIC in the US Army* (30 Volumes). Volume VIII (*The CIC With Special Projects*). Part-III: *CIC With the ALSOS Mission*, pp. 116–130 [NARA RG 319, Entry UD-1080, Box 3]**

[This document generally gives the same information as the *Manhattan District History* previously quoted, but in much less detail. The few noteworthy exceptions are included below.]

[...] In December 1945 Lt Col George R. Eckman prepared a final report on the ALSOS Mission; it is from this document that the following history of CIC in the Mission has been extracted.[128]

128 "Final Report on the ALSOS Mission," prepared by Lt Col George R. Eckman, (Conf), is on file in the G2 Documents Lib, Pentagon, Wash DC.

[...] On 22 March, Colonel Pash led the ALSOS "spearhead" group into Ludwigshaven while the city was still being shelled by the enemy, who were holding their bridgehead on the west side of the Rhine to protect their retreat. The ALSOS party proceeded at once to the huge I. G. Farben Industries plant and secured guards for this important target from the armored unit driving through the city toward the Rhine. This major war plant was held by the ALSOS team and attached guards until the "T" Force moved in the next day.

[...] Other targets visited by members of the Northern Base during this closing period of the war in Europe included personnel and institutional objectives at Hamburg, Jena, Braunschweig, Clauthal, Halle, Erfurt, and Essen. In the early days of May, ALSOS investigators uncovered additional caches of uranium compounds and "heavy" water which had been hidden away by the Nazis in the Harz and the Bavarian Mountains.

[...] During the early planning stages of ALSOS in 1943 and early 1944, many potential Berlin targets had been evaluated and listed for ultimate examination. However, as ALSOS intelligence was collected in operations in the liberated countries and Western Germany, it became evident that Berlin would become an area of only secondary interest. Most high priority targets had already been discovered by the ALSOS teams.

As the Air Force continued to rain down high explosives on the city, many of the war research laboratories and bureaus of institutes and factories were evacuated or obliterated. Following the German surrender and the Soviet Occupation of Berlin, it was expected that what ALSOS targets remained had been thoroughly "worked over" by Russian intelligence agencies.

There were certain missing items, however, that ALSOS officials thought might be discovered among the rubble of Berlin, and Colonel Pash headed a party of 14 Mission members that entered Berlin on 28 July. Three weeks were spent in following investigative leads, including documents and personnel of the Kaiser Wilhelm Institute. The effort was well spent, for a number of additional facts were added to the ALSOS dossiers.

The Berlin Operation was the last major expedition of the Mission. Colonel Pash returned to Paris headquarters in the second week of August 1945.

[The Pentagon Library told me that they do not have a copy of Eckman's final report. Did the Pentagon Library actually lose the final report of one of their most famous missions? Can a copy of this report be located someplace?]

Leslie R. Groves. 1962. *Now It Can Be Told: The Story of the Manhattan Project.* New York: Harper.

[The three chapters on Alsos in Groves's book appear to be very closely based on the *Manhattan District History* quoted previously. The events, details, and wording of the sentences are all highly similar. The most noteworthy exceptions are included below.]

[pp. 196–197:] Thorium seemed out of the question, since it is mined chiefly in Brazil and India and, because of embargoes, Germany had been unable to import any since the war began, and had had only insignificant stocks on hand before the war. The basic fuel was thought to be uranium. Considering our own firsthand knowledge of the enormous industrial effort required to produce U-235, we were confident that we would have seen evidences of any such program had one existed. It seemed more likely that they would use plutonium. That they had enough to launch an atomic program seemed to be within the realm of possibility, for we knew there had been a large stockpile of refined uranium ore at Oolen, Belgium, a few miles outside Brussels, which originally had been the property of Union Minière.

The only other possible supply of uranium was the mines at Joachimsthal, Czechoslovakia, which was not a particularly significant source. Most of this ore was shipped to a uranium plant outside Berlin, the Auer-Gesellschaft. British Intelligence kept in touch with the activities of these mines, and in July, 1944, Calvert's group started periodic aerial surveillance over the entire mining area, studying the pictures in detail for new shafts and aboveground activity. Tailing piles from each mine were microscopically measured from one reconnaissance to the next. By knowing the general grade of the ore and measuring the piles, we could determine with some degree of accuracy the mine's daily production. There were no signs of extraordinary activity.

[pp. 230–231:] I have always considered Goudsmit's opinion much to the point: "On the whole, we gained the definite impression that German scientists did not support their country in the war effort. The principal thing was to obtain money from the government for their own researches, pretending that they might be of value to the war effort. One genuine selling point which they used extensively was that pure research in Germany in many fields was far behind the United States."

Although most of our objectives in Germany lay in the French zone of advance, one that was particularly important to us—the Auergesellschaft Works in Oranienburg, about fifteen miles north of Berlin—lay in what was to be the Russian zone. The information that Alsos had uncovered in Strasbourg had confirmed our earlier suspicions that the plant was engaged in the manufacture of thorium and uranium metals which were to be used in the production of atomic energy and hence probably for the manufacture of an atomic bomb. Since there was not even the remotest possibility that Alsos could seize the works I recommended to General Marshall that the plant be destroyed by air attack.

When he approved, I sent Major F. J. Smith, of my office, to explain the mission to General Carl Spaatz, who was then in command of our Strategic Air Forces in Europe. Spaatz co-operated wholeheartedly and, in the period of about thirty minutes during the afternoon of March 15, 612 Flying Fortresses of the Eighth Air Force dropped 1,507 tons of high explosives and 178 tons of incendiary bombs on the target. Poststrike analysis indicated that all parts of the plant that were aboveground had been completely destroyed.

[pp. 238–239:] [...O]n April 23, I handed the following memorandum to General Marshall:

> In 1940 the German Army in Belgium confiscated and removed to Germany about 1200 tons of uranium ore. So long as this material remained hidden under the control of the enemy, we could not be sure but that he might be preparing to use atomic weapons.
>
> Yesterday I was notified by cable that personnel in my office had located this material near Stassfurt, Germany, and that it was now being removed to a safe place outside of Germany where it would be under the complete control of American and British authorities.
>
> The capture of this material, which was the bulk of uranium supplies available in Europe, would seem to remove definitely any possibility of the Germans making any use of an atomic bomb in this war.

[pp. 245–246:] In the fall of 1944, Himmler's Security Service Organization apparently became interested in the atomic project and formed a War Research Pool, which remained under Göring to avoid duplication and useless work. Himmler's people did not seem to be entirely satisfied with progress under the National Research Council, however, and they subsequently proposed a plan to remove all obstacles to the project and obtain maximum results. Although this plan was sound, it came too late.

[p. 248:] After V-E Day, a number of searches for specific information and materials were conducted in various parts of Germany. Alsos sent groups to Berlin and Salzburg, but, by that time, I was no longer too much concerned with their work, beyond insuring that no information remained that might eventually fall into Russian hands. These operations only confirmed what we already knew and it was quite clear that there was nothing in Europe of further interest to us.

[In his book, Groves concealed most of his knowledge of and interactions with the German nuclear program.

For much more information on what really happened, see the files and sources in Section D.14.

As also shown in Section D.14, there are many further files that still remain classified even after all this time. People should advocate to have all files on this topic located, declassified, and released in archival collections around the world.]

D.1.2 Farm Hall Recordings

[Ten German nuclear scientists (Erich Bagge, Kurt Diebner, Walther Gerlach, Otto Hahn, Paul Harteck, Werner Heisenberg, Horst Korsching, Max von Laue, Carl Friedrich von Weizsäcker, and Karl Wirtz) rounded up by the Alsos Mission were kept under house arrest from July 1945 until January 1946 at Farm Hall in Great Britain, where their private conversations were recorded without their knowledge. The transcripts were not released to the public until 1992.]

Farm Hall transcripts [page numbers refer to Frank 1993; see also Bernstein 2001, Hoffmann 2023, and NARA RG 77, Entry UD-22A, Boxes 164–165.]

[Farm Hall Report 1, 6 July, soon after arrival, p. 33:]

DIEBNER: I wonder whether there are microphones installed here?

HEISENBERG: Microphones installed? (laughing) Oh no, they're not as cute as all that. I don't think they know the real Gestapo methods; they're a bit old fashioned in that respect.

[Farm Hall Report 2, 18 July, p. 46:]

WIRTZ: A man like GOUDSMIT doesn't really want to help us; he has lost his parents.

HARTECK: Of course GOUDSMIT can't forget that we [Germans] murdered his parents. That's true too and it doesn't make it easy for him.

DIEBNER: I would imagine that we will be given more freedom the moment the Russians say: "We agree, you will take over the scientists". They are negotiating with the Russians as to who shall be handed over to Russia and who shall not. Presumably that is being discussed in Berlin now.

[Farm Hall Report 2, 21 July, pp. 55–57:]

BAGGE: For the sake of the money, I should like to work on the Uranium-engine; on the other hand, I should like to work on cosmic rays. I feel like DIEBNER about this.

KORSCHING: Would you both like to construct a Uranium-engine?

DIEBNER: This is the chance to earn a living.

KORSCHING: Every layman can see that these ideas are exceedingly important. Hence there won't be any money in it. You only make money on ideas which have escaped the general public. If you invent something like artificial rubies for the watch making industry, you will make more money than with the Uranium-engine. Well, DIEBNER, we'll both go to the Argentine.

DIEBNER: I shall come with you. [...]

KORSCHING: Still, I should like to get to HECHINGEN once more to collect the rest of my things. After all I still have all my books there and the telescope—though mind you I have hidden it from the French. Of course I did not hand that over. I have got all my glass prisms, lenses, etc. I lifted a floorboard, hid the stuff and nailed the board down again. [...]

KORSCHING: [Talking to BAGGE...] (DIEBNER leaves the room) If you work together with HEISENBERG on a Uranium-engine, then you can write off your share. If you want to work on a Uranium-engine, then you would have to do it somewhere else. Of course it would be an idea to go to the Argentine with 2 people and say: “Here we are, we know how to do this and that; we have a good method for the separation of isotopes, we do not need to produce heavy water.” Somehow in this fashion we have to do it. It would not come to anything if you collaborated with HEISENBERG on a Uranium-engine. They did not even bring along the small fry to this place; that is how outsiders judge the work. They get there and read all the secret reports before they take the people away from there.

BAGGE: How long before did they have the secret reports?

KORSCHING: Two or three days before. The principal question which GOUDSMIT put to me, was “Is that your idea? Has that been published already is that anything new?”—that is all he wanted to know. And BOPP and FISCHER they just ignore one and say “Oh well, they just made some calculations for HEISENBERG.” Apart from that for instance, the ordering of apparatus from the firms and all the other various things which we have done, WIRTZ just told him (GOUDSMIT): “I have done that.” Do you think WIRTZ is going to be modest in front of Mr. GOUDSMIT? No [...] And that is how WIRTZ has excluded them. GOUDSMIT takes his word for it. BOPP was quite disgusted and astonished that suddenly he was dropped like that. And that is how it is all over the world. A scientist is asked “What have you thought out, where is your idea?” If you then make the strategic mistake of moving in the shadow of a man who is already world famous, then you are out of the limelight for the rest of your life and if you then raise your voice against that, then on top of it you will be called a trouble maker.

[Farm Hall Report 2, 30 July, p. 50:]

HAHN: I read an article in the Picture Post about the Uranium bomb; it said that the newspapers had mentioned that such a bomb was being made in Germany. Now you can understand that we are being “detained” because we are such men. They will not let us go until they are absolutely certain that no harm can be done or that we will not fall into Russian hands or anything like that. To my mind it is a mistake to do anything. [...]

[Farm Hall Report 3, 5 August, p. 68:]

DIEBNER: It doesn’t look as though BOTHE will join us.

BAGGE: I think GEHLEN (?) is behind it. It looks as though GEHLEN (?) had the decency to keep BOTHE informed of what was going on so that BOTHE could make his plans as far as these people are concerned and act accordingly. [...]

DIEBNER: In the end we really had no more radium. There was an awful row as someone wanted some. I fetched another 3 grammes at the last moment.

BAGGE: Didn't firms like BRAUNSCHWEIGISCHE CHEMIEFABRIK have any more?

DIEBNER: I don't know. They may have had 1 gramme; all the rest had been requisitioned by the State. I got mine from the HARZ, I sent a car specially for it.

BAGGE: That was the Reichsstelle for radium?

DIEBNER: Yes, the Reichsstelle for Chemistry had the radium—25 g (?).

BAGGE: It's a pity they didn't hide 10 grammes out of the 24 grammes.

DIEBNER: I wasn't there. If I had been there we wouldn't have handed it over. The cars drove up and it disappeared. A pity, I had made up my mind not to hand it over.

[Farm Hall Report 4, 6 August discussion after learning of Hiroshima, pp. 70–79:]

HAHN: They can only have done that if they have uranium isotope separation.

WIRTZ: They have it too.

HAHN: I remember SEGRE's, DUNNING's and my assistant GROSSE's work; they had separated a fraction of a milligramme before the war, in 1939.

LAUE: 235?

HAHN: Yes, 235.

HARTECK: That's not absolutely necessary. If they let a uranium engine run, they separate "93".

HAHN: For that they must have an engine which can make sufficient quantities of "93" to be weighed.

GERLACH: If they want to get that, they must use a whole ton. [...]

GERLACH: They have got "93" and have been separating it for two years, somehow stabilised it at low temperature and separated "93" continuously.

HAHN: But you need the engine for that.

DIEBNER: We always thought we would need two years for one bomb. [...]

HEISENBERG: I still don't believe a word about the bomb but I may be wrong. I consider it perfectly possible that they have about ten tons of enriched uranium, but not that they can have ten tons of pure U. 235.

HAHN: I thought that one needed only very little 235.

HEISENBERG: If they only enrich it slightly, they can build an engine which will go but with that they can't make an explosive which will—

HAHN: But if they have, let us say, 30 kilogrammes of pure 235, couldn't they make a bomb with it?

HEISENBERG: But it still wouldn't go off, as the mean free path is still too big.

HAHN: But tell me why you used to tell me that one needed 50 kilogrammes of 235 in order to do anything. Now you say one needs two tons.

HEISENBERG: I wouldn't like to commit myself for the moment, but it is certainly a fact that the mean free paths are pretty big. [...]

HARTECK: Do you want 4 or 5 centimetres,—then it would break up on the first or second collision.

HEISENBERG: But it needn't have the diameter of only 4 or 5 centimetres.

HAHN: I think it's absolutely impossible to produce one ton of uranium 235 by separating isotopes.

WEIZSACKER: What do you do with these centrifuges.

HARTECK: You can never get pure 235 with the centrifuge. But I don't believe that it can be done with the . . . centrifuge.

WIRTZ: No, certainly not.

HAHN: Yes, but they could do it too with the mass-spectrographs. EWALD has some patent.

DIEBNER: There is also a photo-chemical process. [...]

WIRTZ: I would bet that it is a separation by diffusion with recycling. [...]

HARTECK: They have managed it either with mass-spectrographs on a large scale or else they have been successful with a photo-chemical process.

WIRTZ: Well I would say photo-chemistry or diffusion. Ordinary diffusion. They irradiate it with a particular wave-length.—(all talking together).

HARTECK: Or using mass spectrographs in enormous quantities. It is perhaps possible for a mass-spectrograph to make one milligramme in one day—say of "235". They could make quite a cheap mass-spectrograph which, in very large quantities, might cost a hundred dollars. You could do it with a hundred thousand mass-spectrographs.

HEISENBERG: Yes, of course, if you do it like that; and they seem to have worked on that scale. 180,000 people were working on it.

HARTECK: Which is a hundred times more than we had.

BAGGE: GOUDSMIT led us up the garden path.

HEISENBERG: Yes, he did that very cleverly. [...]

KORSCHING: That shows at any rate that the Americans are capable of real cooperation on a tremendous scale. That would have been impossible in Germany. Each one said that the other was unimportant.

GERLACH: You really can't say that as far as the uranium group is concerned. You can't imagine any greater cooperation and trust than there was in that group. You can't say that any one of them said that the other was unimportant.

KORSCHING: Not officially of course.

GERLACH: (Shouting). Not unofficially either. Don't contradict me. There are far too many other people here who know. [...]

WEIZSACKER: How many people were working on the V 1 and V 2?

DIEBNER: Thousands worked on that. [...]

HARTECK: Considering the figures involved I think it must have been mass-spectrographs. If they had had some other good method they wouldn't have needed to spend so much. One wouldn't have needed so many men. [...]

HEISENBERG: I must say I think your theory is right and that it is spectrographs.

WIRTZ: I am prepared to bet that it isn't.

HEISENBERG: What would one want 60,000 men for?

KORSCHING: You try and vaporise one ton of uranium.

HARTECK: You only need ten men for that. I was amazed at what I saw at I.G.

HEISENBERG: It is possible that the war will be over tomorrow.

HARTECK: The following day we will go home.

KORSCHING: We will never go home again.

HARTECK: If we had worked on an even larger scale we would have been killed by the "Secret Service". Let's be glad that we are still alive. Let us celebrate this evening in that spirit.

DIEBNER: Professor GERLACH would be an Obergruppenführer and would be sitting in LUXEMBOURG as a war criminal. [...]

WEIZSACKER: If you had wanted to a make a bomb we would probably have concentrated more on the separation of isotopes and less on heavy water.

(HAHN leaves the room)

WEIZSACKER: If we had started this business soon enough we could have got somewhere. If they were able to complete it in the summer of 1945, we might have had the luck to complete it in the winter of 1944/45.

WIRTZ: The result would have been that we would have obliterated LONDON but would still not have conquered the world, and then they would have dropped them on us. [...]

HARTECK: The uranium content in the stone in the radium mines near GASTEIN was said to be so great that the question of price does not come into it.

BAGGE: There must be enormous quantities of uranium in UPPER SILESIA. Mining experts have told me that.

DIEBNER: Those are quite small quantities. [...]

HEISENBERG: About a year ago, I heard from SEGNER (?) from the Foreign Office that the Americans had threatened to drop a uranium bomb on Dresden if we didn't surrender soon. At that time I was asked whether I thought it possible, and, with complete conviction, I replied: "No."

WIRTZ: I think it characteristic that the Germans made the discovery and didn't use it, whereas the Americans have used it. I must say I didn't think the Americans would dare to use it.

Top Secret cable 70221 from U.S. Military Attaché London England to War Department. 25 January 1946 [NARA RG 77, Entry UD-22A, Box 160, Folder 205.2 Cables Incoming, Top Secret January 1946 thru December 1946]

SUBJECT: Future Disposition of the Guests.

TO: Colonel W. R. Shuler, Room 5004, New War Department Building, Washington, D. C.

-#7022 f. 25 Jan 46 R.

1. Repeating a cable dispatched to you this afternoon. A meeting was held at the War Cabinet Office yesterday afternoon on the future of the guests. Attending were:

Brigadier C.F.C. Spedding. In charge of guests in Germany.
Dr. Frazer. Scientific adviser to Spedding.
Mr. Rickett. Secretary to Sir John Anderson.
Michael Perrin.
Lt. Colonel E. P. Dean

2. The plan of the Control Commission as presented by Brigadier Spedding was as follows:

(a) Harteck will return to his old post at the University of Hamburg. This proposal was so logical that it evoked no discussion.

(b) Gerlach will proceed to the University of Bonn.

(c) Diebner, who was always more of an administrator than a scientist, will be detached from the others and probably be arrested as a professional Nazi.

(d) Hahn, Heisenberg, von Laue, von Weizsacker, Wirtz, Korsching, and Bagge will go to the University of Goettingen.

3. Goettingen is only ten miles from the Russian Zone. Originally this was considered too close and was ruled out as a place for the guests. Nevertheless, in the end the group referred to in paragraph 1 unanimously agreed in sending the men to Goettingen.

4. There already exists in that part of the University, which the guests will use, a barbed wire enclosed area or compound. This will be retained as a security measure - not so much to keep the guests inside as to keep others out. The guests will work and live within the compound. They will have free access to the outside. The existence of the compound does, however, make a forced departure by any one of them more difficult.

5. Gottingen has excellent laboratory facilities, the best of any university in the British Zone. There are adequate apartments or flats within the compound, thus enabling the guests to be rejoined by their families.

6. The British are endeavoring to build up Gottingen in all respects as the outstanding intellectual center in their Zone. Thus the guests will have more intellectual comradeship here than any other place.

7. All the men referred to in paragraph 1 agreed on the following. From a selfish U.S. and U.K. point of view, the best thing what could happen is for the guests to remain in Germany and resume their old work. Their knowledge of fission is about that of 1939. It would take them a couple of years by their own resources to catch up with what has transpired in the U.S. and U.K. The best guarantee which the U.S. and U.K. governments have that the guests will remain in Germany is, in the last analysis, the willingness of these men to remain in their homeland. Men of their background do not demand a great number of worldly goods. They must, however, have access to laboratory facilities and intellectual comradeship. With these conditions met, they will not be tempted by outside offers. The evidence is copious that German scientists tempted to go to Russia are only tempted because they have no laboratory facilities at home.

8. It is the conclusion of this office that the Gottingen proposal is the best of any realistic solution.

9. It is hoped that this letter, carried by Captain Sturges, will reach you before the British proposal is cabled to Washington.

For the Military Attache:

Edgar P. Dean.
EDGAR P. DEAN,
Lt. Colonel, AUS,
Assistant to the Military Attache.

NARA RG 77, Entry UD-22A, Box 160, Folder 205.3 Cables Outgoing, Secret and Under January 1946 thru December 1946

Figure D.43: W. R. Shuler to Office of Military Attaché London. 9 January 1946 [NARA RG 77, Entry UD-22A, Box 160, Folder 205.3 Cables Outgoing, Secret and Under January 1946 thru December 1946]. Even the officials responsible for imprisoning and secretly recording ten civilians for six months with no charges, no judicial process, and no International Red Cross visitation stated in writing that they were concerned the operation was illegal. That raises interesting questions, such as whether the modern families of those ten civilians might be entitled to financial and legal restitution from the U.K. and U.S. governments.

[The Farm Hall transcripts record the scientists' surprise at news of the 6 August 1945 Hiroshima bombing and do not reveal significant apparent knowledge of nuclear weapons design and development. Proponents of the conventional history use that evidence to argue that the German nuclear program never attempted or accomplished much. However, that argument assumes that all of the following three conditions are true:

1. It assumes that these ten scientists knew all of the details of the German nuclear program. Wartime German programs such as the nuclear work, chemical weapons development, and other advanced military programs were highly secretive and compartmentalized, such that each individual scientist knew only what they needed to know in order to do their job. Max von Laue does not appear to have even been involved in the wartime nuclear program, and some of the others may not have played major roles in it.

2. It assumes that the scientists were telling the truth and the whole truth in their recorded conversations. These scientists had just survived more than a decade in Germany where secret SS informers and hidden microphones were commonplace, so that they had had to be very careful with their words at all times in order to survive. Almost immediately after arriving at Farm Hall, Diebner openly speculated to the other scientists that there could be microphones there. Later, Hahn stated that the German scientists would only be released if the Allies were convinced that they were harmless. Still later, Harteck said they would be killed if the Allies thought they had done "larger scale" work. Diebner said they would be tried as war criminals if that were the case. The 25 January 1946 cable demonstrates that even at the end of the Farm Hall internment, Allied officials were still formally debating which if any of the German scientists to put on trial. In addition to the Germans' open acknowledgement of the possibility that microphones might be present, presumably they would have been very cognizant that their British hosts might overhear their conversations, or even that some of their own members (such as von Laue or others) might give the British information about the others' conversations. Thus it would be reasonable to assume that the scientists withheld a great deal of useful information from their conversations, or even gave false information to make themselves appear as naive as possible for any audience that might be listening.

3. It assumes that the published Farm Hall transcripts contain all relevant conversations. However, the transcripts give just a small faction of the conversations that would have occurred with ten scientists interacting among themselves and with their British hosts on a daily basis over a period of six months. The original tapes were reused for new recordings and consequently unavailable. Even the original German conversations are unavailable—all that survives in the written transcripts are English translations of those conversations. It is possible that the scientists found locations or methods for conversing that were not recorded. Finally, if a particular conversation had revealed an advanced German nuclear program, would that conversation have been released with the other transcripts (which were all classified until 1992), or might it have been handled differently and remain classified to this day?

For comparison, imagine that after World War II, ten scientists from the United States (a few who had held significant positions in the Manhattan Project but most who had not) were captured by Soviet forces and held for six months in a house in Moscow that they knew was bugged. Imagine that those captured scientists deeply feared that if they said the wrong thing, they could be forced to work in the Soviet Union for the rest of their lives, be imprisoned for the rest of their lives, or be executed as war criminals. No credible scholars would expect the resulting transcripts to be a complete and accurate account of all people, places, and work that had been involved in the entire

Manhattan Project. Likewise no credible scholars should expect the Farm Hall transcripts to be a complete and accurate account of all people, places, and work that had been involved in the entire German nuclear program.

Hahn complained that during that war, Heisenberg used to say "that one needed 50 kilogrammes of 235 in order to do anything" (which is a very good value for the required mass of U-235 without implosive compression; the U.S. Little Boy bomb used 64 kg of 80% U-235), but that in Allied custody Heisenberg had changed to saying he thought it was two tons. This seems to be a good example of the German scientists making their Allied interrogators believe that the wartime work was much less advanced than it actually was.

The conventional historical view is that roughly 100 or fewer people worked on the German nuclear program. Harteck seemed to indicate that he knew of approximately 1800 people working on the program, and there may have been many others of whom he was not aware.

The scientists remarked that Samuel Goudsmit was very prejudiced because his parents had been killed in the Holocaust. They were surprised that Goudsmit simply asked each scientist what work he had done and just "takes his word for it."

Harteck said that one ton of uranium could be vaporized for enrichment by as few as ten men, saying that he was "amazed at what [he] saw at I.G." Farben. What did he see? Which I.G. Farben facility was that? Did I.G. Farben have a large-scale uranium enrichment program, or technologies that could have been readily adapted to large-scale enrichment? Note that as soon as Harteck brought up this mysterious large-scale activity at I.G. Farben, the other scientists immediately changed the subject.

For more information on the development in the German-speaking world of a "photochemical process" for isotope separation that requires irradiation "with a particular wavelength," see p. 3664.]

D.1.3 Postwar Public Statements by a Few German Nuclear Scientists

[In their public interviews and writings in the years after the war, German scientists professed a lack of desire, plans, materials and/or political support to produce nuclear weapons for the Third Reich [Cassidy 1992; Heisenberg 1953, 1971; Irving 1967; Powers 1993; NYT 1948-12-28 p. 10].

However, only a small number of nuclear scientists went on the public record. It is not clear how much of what they said was factual history versus personal spin meant to avoid postwar criticism; the answer may vary for different scientists in question. Certainly it would have been in their best personal interests to downplay their support for weapons-related work as much as possible.

Based on these postwar statements, as well as the Alsos and Farm Hall reports, history books for the last 75+ years have primarily focused on Werner Heisenberg's KWI research group without sufficiently considering other groups, and have concluded that Germany never even made a serious attempt to build an atomic bomb, let alone made significant progress toward one. The greatest difference among these books is where they fall on a spectrum ranging from viewing the German scientists' motives and competence more favorably [e.g., Irving 1967; Powers 1993], in relatively neutral terms [e.g., Walker 1989, 1995, 2020, 2024a, 2024b], or less favorably [e.g., Goudsmit 1947; Rose 1998].]

Werner Heisenberg. 1971. *Physics and Beyond: Encounters and Conversations*. New York: Harper & Row. pp. 182–183.

In the autumn of 1941, when we thought we had a fairly clear picture of the technical possibilities, we asked the German Embassy in Copenhagen to arrange a public lecture for me there. I think I arrived in Denmark in October 1941, and when I visited Niels in his home in Carlsberg, I did not broach the dangerous subject until we took our evening walk. Since I had reason to think that Niels was being watched by German agents, I spoke with the utmost circumspection. I hinted that it was now possible in principle to build atom bombs, but that a tremendous technological effort was needed, and that physicists ought perhaps to ask themselves whether they should work in this field at all. Unfortunately, as soon as I mentioned the mere possibility of making atom bombs, Niels became so horrified that he failed to take in the most important part of my report, namely, that an enormous technical effort was needed. Now this, to me, was so important precisely because it gave physicists the possibility of deciding whether or not the construction of atom bombs should be attempted. They could either advise their governments that atom bombs would come too late for use in the present war, and that work on them therefore detracted from the war effort, or else contend that, with the utmost exertions, it might just be possible to bring them into the conflict. Both views could be put forward with equal conviction, and, in fact, during the war it turned out that even in America, where conditions were incomparably more favorable for the attempt than in Germany, the atom bomb was not made ready before V-E Day.

Niels, as I have said, was so horrified by the very possibility of producing atomic weapons that he did not follow the rest of my remarks. Perhaps he was also too filled with justifiable bitterness at the brutal occupation of his country by German troops to entertain any hopes of international understanding among physicists. I found it most painful to see how complete was the isolation to which our policy had brought us Germans, and to realize how war can cut into even the most long-standing friendships, at least for a time.

Despite this failure of my mission to Copenhagen, the German "uranium club" was in a relatively simple situation. The government decided (in June 1942) that work on the reactor project must be continued, but only on a modest scale. No orders were given to build atom bombs, and none of us had cause to call for a different decision. As a result, our work helped to pave the way for a peaceful atomic technology in the postwar period, and as such it was to bear useful fruits, despite and after all the destruction.

[Heisenberg's postwar claims that Germany never attempted to develop nuclear weapons are disproven by:

- Niels Bohr's letter below.
- Heisenberg's 1942 presentation to German government and military officials informing them that a uranium-235 or plutonium bomb with a fission pit about the size of a pineapple could destroy a large Allied city and could be built within two years if sufficient resources were allocated (pp. 3350– 3351).
- Photos from 1943 of Hitler with Heisenberg and other nuclear scientists who were working on a high-priority project for the war (pp. 3877–3879).
- The 15 September 1945 final report by the joint chairs of CIOS, U.S. General Thomas Jeffries Betts, Deputy G-2 of SHAEF, and U.K. Ministry of Supply chief advisor and F.R.S. Professor Reginald Patrick Linstead: "Authorities stated that KWI had repeatedly assured Hitler that an atomic explosive would be available for use within a comparatively short time" (p. 5030).
- Hundreds of other documents quoted or cited throughout the rest of this appendix.]

Unsent draft letter from Niels Bohr to Werner Heisenberg, undated (circa 1958). [Document 1 at: https://www.nbarchive.dk/collections/bohr-heisenberg/documents/ See also other Bohr letters to the same effect at that website.]

[...] Personally, I remember every word of our conversations, which took place on a background of extreme sorrow and tension for us here in Denmark. In particular, it made a strong impression both on Margrethe and me, and on everyone at the Institute that the two of you spoke to, that you and Weizsäcker expressed your definite conviction that Germany would win and that it was therefore quite foolish for us to maintain the hope of a different outcome of the war and to be reticent as regards all German offers of cooperation. I also remember quite clearly our conversation in my room at the Institute, where in vague terms you spoke in a manner that could only give me the firm impression that, under your leadership, everything was being done in Germany to develop atomic weapons and that you said that there was no need to talk about details since you were completely familiar with them and had spent the past two years working more or less exclusively on such preparations. I listened to this without speaking since [a] great matter for mankind was at issue in which, despite our personal friendship, we had to be regarded as representatives of two sides engaged in mortal combat. That my silence and gravity, as you write in the letter, could be taken as an expression of shock at your reports that it was possible to make an atomic bomb is a quite peculiar misunderstanding, which must be due to the great tension in your own mind. [...] If anything in my behaviour could be interpreted as shock, it did not derive from such reports but rather from the news, as I had to understand it, that Germany was participating vigorously in a race to be the first with atomic weapons.

Besides, at the time I knew nothing about how far one had already come in England and America, which I learned only the following year when I was able to go to England after being informed that the German occupation force in Denmark had made preparations for my arrest.

Document Section, Third Army, Freising, Bavaria. 1945 translation. Memo on a letter re Heisenberg from Himmler to the SS Dozentenführer in Leipzig (in the files at Freising). [NARA RG 77, Entry UD-22A, Box 167, Folder 32.12-2 GERMANY: Personnel (Jan 45–Dec 45)]

Memo on a letter re Heisenberg from Himmler to the SS Dozentenführer in Leipzig (in the files at Freising)

1. Himmler thanks and congratulates the Leipzig SD for the very thorough and accurate report on Heisenberg.

2. While it is evident that Heisenberg's attitude (I think he used the word "Anshauung") was not exactly in line with that prescribed by the party, I (Himmler) regard him as essentially decent (anständig), and want the SS and SD organizations in Leipzig and the University informed of that fact.

3. In view of his comparative youth and influence and ability to attract future scientists (Nachwuchs), we cannot permit ourselves to remove or to kill him. (können wir uns es nicht erlauben diesen Mann beiseite zu setzen oder zu töten.)

4. It would be highly desirable to get Heisenberg to write a scientific article for one of the publications of the SS. Dr. Wüst is probably the best person to approach him on this subject.

5. It is hoped that Heisenberg can ultimately be brought to work with us, possibly within the framework on the Ahnenerbe.

[See document photo on p. 3349.

This document does not indicate the date of the Himmler letter it is translating, but that was probably July 1938; see for example Powers 1993, pp. 41–43.]

The Himmler letter being translated was probably from July 1938.

So gross wie eine Ananas... *Der Spiegel* 4 June 1967, pp. 80–93.

Noch während der Vorbereitungen, am 4. Juni 1942, wurde Heisenberg zur entscheidenden Geheimsitzung des deutschen Atom-Gremiums nach Berlin berufen: Die Mitglieder der “Uran-Gemeinschaft” sollten dem neuen Reichsminister für Bewaffnung und Munition, Albert Speer, Bericht erstatten und mit ihm die Zukunft der deutschen Uranforschung erörtern.

Zwei Monate zuvor hatte Göring Order gegeben, daß alle Programme, die nur für die Nachkriegszeit Bedeutung hätten, zu unterlassen seien. Allein Albert Speer konnte entscheiden, ob irgendein Unternehmen von dieser Bestimmung ausgenommen wurde.

Sie trafen sich im Helmholtz-Hörsaal des Harnack-Hauses in Dahlem:

> Auf der einen Seite die Forscher Hahn und Heisenberg, Diebner, Harteck und Wirtz sowie der Präsident der Kaiser-Wilhelm-Gesellschaft, Dr. Albert Vögler.

> Auf der anderen Seite Rüstungsminister Speer, sein technischer Berater Karl-Otto Saur, VW-Konstrukteur Ferdinand Porsche sowie die Militärs Leeb, Fromm, Milch und Witzell.

Man muß sich vergegenwärtigen, daß während der vorangegangenen Wochen die schweren Flächenangriffe der Royal Air Force auf deutsche Städte begonnen hatten. Lübeck und Rostock lagen bereits in Trümmern, Köln war in der Nacht zum 31. Mai von mehr als tausend britischen Bombern heimgesucht worden—und der Generalinspekteur und Generalzeugmeister der Luftwaffe, Generalfeldmarschall Erhard Milch, war begierig auf Vergeltung.

So kam Heisenberg sogleich auf die militärischen Anwendungsmöglichkeiten der Kernspaltung zu sprechen—auf Uran 235 und auf Plutonium.

While preparations were still underway, on 4 June 1942 Heisenberg was summoned to Berlin for the crucial secret meeting of the German atomic body: The members of the “uranium club” were to report to the new Reich Minister of Armaments and Munitions, Albert Speer, and discuss with him the future of German uranium research.

Two months earlier, Goering had given orders that all programs that were only relevant to the postwar period were to be omitted. Albert Speer alone could decide whether any enterprise was exempt from this provision.

They met in the Helmholtz lecture hall of the Harnack House in Dahlem:

> On one side the researchers Hahn and Heisenberg, Diebner, Harteck and Wirtz, and the president of the Kaiser Wilhelm Society, Dr. Albert Vögler.

> On the other side, armaments minister Speer, his technical advisor Karl-Otto Saur, VW designer Ferdinand Porsche, and the military officers Leeb, Fromm, Milch and Witzell.

It must be remembered that during the preceding weeks, the Royal Air Force’s heavy area raids on German cities had begun. Lübeck and Rostock were already in ruins, Cologne had been hit by more than a thousand British bombers on the night of May 31—and the Inspector General and Generalzeugmeister of the Luftwaffe, Field Marshal Erhard Milch, was eager for retaliation.

So Heisenberg immediately turned to the military applications of nuclear fission—to uranium-235 and to plutonium.

Als er sein Referat beendet hatte, ergab sich ein knapper Dialog, der allen Anwesenden lebhaft in Erinnerung geblieben ist.

Milch erkundigte sich nach der Größe einer Bombe, deren Wirkung genügen würde, eine große Stadt zu zerstören.

Heisenberg: “Etwa so groß wie eine Ananas.” Er bezog sich auf die Explosivladung und demonstrierte ihren Umfang mit den Händen.

Als er der Unruhe unter den anwesenden Militärs gewahr wurde, dämpfte er ihren Enthusiasmus: Eine solche Waffe lasse sich nicht innerhalb weniger Monate produzieren; und sollten die Amerikaner auch bald einen Uranmeiler und in frühestens zwei Jahren eine Uranbombe haben—in Deutschland sei ihre Herstellung unter den gegebenen Umständen eine wirtschaftliche Unmöglichkeit.

“Ich war sehr glücklich”, so gestand Heisenberg sechs Jahre später in einem Brief, “daß uns jede Entscheidung abgenommen war: Die damals ausgegebenen Führerbefehle verhinderten jeden großen Einsatz für Atombomben.”

Hingegen betonte Heisenberg immer wieder, ein Reaktor sei von größter Bedeutung, sowohl für aktuelle militärische als auch für zivile Zwecke nach dem Kriege.

Die Partie, die eine Entscheidung hatte bringen sollen, endete pari: Das Vorhaben wurde weder eingestellt noch besonders unterstützt.

Speer genehmigte den Bau eines Bunkers, der—auf dem Gelände des Kaiser-Wilhelm-Instituts für Physik—den ersten großen deutschen Uranreaktor aufnehmen sollte.

When he had finished his paper, a brief dialogue ensued that has been vividly remembered by all present.

Milch inquired about the size of a bomb whose effect would be enough to destroy a large city.

Heisenberg: “About the size of a pineapple.” He referred to the [fissile] explosive charge and demonstrated its size with his hands.

When he became aware of the agitation among the military officers present, he dampened their enthusiasm: Such a weapon could not be produced within a few months. The Americans might also soon have a uranium pile, and in two years at the earliest a uranium bomb. In Germany producing it was an economic impossibility under the given circumstances.

“I was very happy,” Heisenberg confessed in a letter six years later, “that every decision had been taken from us: the Führer orders issued at that time prevented any great effort for atomic bombs.”

By contrast, Heisenberg repeatedly stressed that a reactor was of paramount importance, both for current military and postwar civilian purposes.

The match that should have brought a decision ended at par: the project was neither stopped nor particularly supported.

Speer approved the construction of a bunker that would house—on the site of the Kaiser Wilhelm Institute of Physics—the first large German uranium reactor.

[There are several other accounts of the “pineapple” story; see for example the sources in Powers 1993, pp. 515–516.]

MEMORANDUM: Re The Future of German Science.

TO : Major Fisher.

Additional contacts with many German scientists in the Göttingen and Heidelberg areas, and conversations with scientists in Holland, Belgium and France have amended the rather favorable impressions left by the first contacts with German scientists.

A. Comments and Experiences.

1. There are a few international scientific undertakings in which the Germans had a major share. Some of these are nearly completed and the scientific material is now in Germany. Examples are quoted in Appendix I. These undertakings should be completed, preferably by the men who have done the earlier work. The examples quoted are in the nature of large "routine projects" rather than research projects and their completion will be important to Allied scientists. The latter are at present in no position to take over these routine projects.

2. Several German scientists have used the war to enrich their institutions at the cost of their colleagues in occupied lands. Examples are quoted in Appendix II.

3. The attitude of German scientists toward world problems may be illustrated by the views of Heisenberg, who is perhaps the most prominent among German scientists. In a visit to Holland during the winter of 1943-44, he said to Prof. Casimir of Eindhoven: "History legitimates Germany to rule Europe (and later the world)." Heisenberg knew about the German concentration camps and the looting of other countries by Germany, yet he wanted Germany to rule. He explained his position this way: "Only a nation which rules ruthlessly can maintain itself. Democracy cannot develop sufficient energy to rule Europe. There are, therefore, only two possibilities: Germany and Russia." "Und dann wäre vielleicht ein Europa unter Deutscher Führung das kleinere Übel."

4. Most German scientists and engineers appear devoid of moral responsibility for the consequences of their work. They work hard on their projects, but appear little concerned about the use to which their results are put. In fact, they seem disappointed now that the Allies don't permit them to make V-1, V-2, etc., for our offensive in the Pacific. This lack of social responsibility makes an advanced German science particularly dangerous. The most extreme demonstrations are found in the concentration camps where fingers were grafted through the palms of the hands, hands on breasts, legs together, etc. Such operations were done by surgeons, not "brutes".

In connection with this same attitude, the remarkable lack of feeling of moral guilt should be recorded which is found everywhere among German scientific circles.

5. At present there is among German scientists the tendency to discount the Allied reports on the German concentration camps as exaggerated. They say: "In the first war you told that we were eating Belgian babies." Some of the more ethical among them appear less perturbed about the wrongs done in the concentration camps as the bad name these concentration camps have given Germany. Such a bad name hurts the cause of Germany.

6. The Germans are very good at whining. They have already deceived many of us by arousing undeserved sympathy. In some cases they are already playing the Allies against each other to obtain special favors of one.

Some of us are inclined to prefer Germans individually to French, Belgians, and Dutch, and are apt to be lenient toward Germans for that reason. Such comparisons usually overlook the incalculable harm, mental and physical, done by the Nazis to these small nations and also that many of their best men are dead.

B. Conclusions.

This war has shown the importance of "new weapons", as radar for warning and fire control, proximity fuzes, V-weapons, jet propulsion, etc. None of these weapons could have been developed without expensive applied research. Such research should be made impossible in Germany by allowing only small budgets for research purposes. University education should be designed to create better citizens, not specialized robots. Only after Germans have become responsible world citizens can they be permitted to resume autonomy in research.

Germany has many hundreds of leaders in fields of war research. The most prominent ones and most dangerous to our security should probably be moved to Allied territory in a sort of German enclave for

- 2 -

~~SECRET~~

at least 5 to 10 years. They could do research work of interest to the Allies under decent living conditions for them and their families. This would liquidate the most important part of German "Scientific General Staff." The alternative would be to let such powerful men go to countries where they would be welcomed but potentially dangerous to us.

APPENDIX I. Astronomy has for nearly a century been organized on an international basis, principally because its large programs require the collaboration of many scientists and institutions.

There are two international organizations in Astronomy:

1) The International Astronomical Union, created by the Research Council of the League of Nations in 1919.

2) The Astronomische Gesellschaft, founded by the Germans around 1860.

The first organization (I.A.U.) is indispensable to astronomical research and embraces nearly all astronomers and astronomical research projects of the world. The A.G. has always been dominated by Germans who had always at least half the votes. Shortly before the war the A.G. ousted its Secretary, Prof. Prager, of Berlin-Babelsberg, because he was a Jew. This fact alone condemns the A.G. as a camouflaged German organization. In fact, the astronomers of the occupied western democracies refused to participate in its meetings during the war.

The A.G. has carried out under its auspices three projects that are valuable:

a. The repetition of the A.G. star catalogue. The work was done at the Rechen Institut, Berlin and the Observatories of Hamburg-Bergedorf and Bonn.

b. The yearly issuance of a catalogue and ephemeris of variable stars.

c. The yearly issuance of a catalogue and ephemeris of minor planets.

Project a has been nearly completed. No Allied scientist or group of scientists would be willing to undertake the finishing of this enormous project. It is recommended that it be finished under Allied protection by the German scientists involved, under the supervision of Prof. A. Koppf, Director of the Rechen Institut, Berlin-Dahlem.

Project b could be taken over by the original editor of this catalogue, Prof. R. Prager, who has been at Harvard Observatory for about 6 years now, having been exiled from, and deprived of his files in, Germany.

Project c could be taken over by Prof. D. Brouwer, Director of Yale Observatory, New Haven, Connecticut, USA, who would be well equipped and is presumably willing to take over this responsibility.

The actual transfer of the files of b and c should be supervised by an astronomer acquainted with the subject.

"Heisenberg... said to Prof. Casimir of Eindhoven: 'History legitimates Germany to rule Europe (and later the world)... Only a nation which rules ruthlessly can maintain itself.'"

Albert Speer. 1970. *Inside the Third Reich.* New York: Macmillan. Chapter 16.

I met regularly for lunch with General Friedrich Fromm in a *chambre séparée* at Horcher's Restaurant. In the course of one of these meetings, at the end of April 1942, he remarked that our only chance of winning the war lay in developing a weapon with totally new effects. He said he had contacts with a group of scientists who were on the track of a weapon which could annihilate whole cities, perhaps throw the island of England out of the fight. Fromm proposed that we pay a joint visit to these men. It seemed to him important, he said, at least to have spoken with them.

Dr. Albert Vögler, head of the largest German steel company and president of the Kaiser Wilhelm Gesellschaft, also called my attention at this time to the neglected field of nuclear research. He complained of the inadequate support fundamental research was receiving from the Ministry of Education and Science, which naturally did not have much influence during wartime. On May 6, 1942, I discussed this situation with Hitler and proposed that Goering be placed at the head of the Reich Research Council—thus emphasizing its importance.[23] A month later, on June 9, 1942, Goering was appointed to this post.

Around the same time the three military representatives of armaments production, Milch, Fromm, and Witzell, met with me at Harnack House, the Berlin center of the Kaiser Wilhelm Gesellschaft, to be briefed on the subject of German atomic research. Along with scientists whose names I no longer recall, the subsequent Nobel Prize winners Otto Hahn and Werner Heisenberg were present. After a few demonstration lectures on the matter as a whole, Heisenberg reported on "Atom-smashing and the development of the uranium machine [sic] and the cyclotron."[24] Heisenberg had bitter words to say about the Ministry of Education's neglect of nuclear research, about the lack of funds and materials, and the drafting of scientific men into the services. Excerpts from American technical journals suggested that plenty of technical and financial resources were available there for nuclear research. This meant that America probably had a head start in the matter, whereas Germany had been in the forefront of these studies only a few years ago. In view of the revolutionary possibilities of nuclear fission, dominance in this field was fraught with enormous consequences.

After the lecture I asked Heisenberg how nuclear physics could be applied to the manufacture of atom bombs. His answer was by no means encouraging. He declared, to be sure, that the scientific solution had already been found and that theoretically nothing stood in the way of building such a bomb. But the technical prerequisites for production would take years to develop, two years at the earliest, even provided that the program was given maximum support. Difficulties were compounded, Heisenberg explained, by the fact that Europe possessed only one cyclotron, and that of minimal capacity. Moreover, it was located in Paris and because of the need for secrecy could not be used to full advantage. I proposed that with the powers at my disposal as Minister of Armaments we build cyclotrons as large as or larger than those in the United States. But Heisenberg said that because we lacked experience we would have to begin by building only a relatively small type.

Nevertheless, General Fromm offered to release several hundred scientific assistants from the services, while I urged the scientists to inform me of the measures, the sums of money, and the materials they would need to further nuclear research. A few weeks later they presented their request: an appropriation of several hundred thousand marks and some small amounts of steel, nickel, and other priority metals. In addition, they asked for the building of a bunker, the erection of several barracks, and the pledge that their experiments would be given highest priority. Plans for building the first German cyclotron had already been approved. Rather put out by these modest requests in a matter of such crucial importance, I suggested that they take one or two million marks and correspondingly larger quantities of materials. But apparently more could not be utilized for the present,[25] and in any case I had been given the impression that the atom bomb could no longer have any bearing on the course of the war.

I was familiar with Hitler's tendency to push fantastic projects by making senseless demands, so that on June 23, 1942, I reported to him only very briefly on the nuclear-fission conference and what we had decided to do.[26] Hitler received more detailed and more glowing reports from his photographer, Heinrich Hoffmann, who was friendly with Post Office Minister Ohnesorge. Goebbels, too, may have told him something about it. Ohnesorge was interested in nuclear research and was supporting—like the SS—an independent research apparatus under the direction of Manfred von Ardenne, a young physicist. It is significant that Hitler did not choose the direct route of obtaining information on this matter from responsible people but depended instead on unreliable and incompetent informants to give him a Sunday-supplement account. Here again was proof of his love for amateurishness and his lack of understanding of fundamental scientific research.

Hitler had sometimes spoken to me about the possibility of an atom bomb, but the idea quite obviously strained his intellectual capacity. He was also unable to grasp the revolutionary nature of nuclear physics. In the twenty-two hundred recorded points of my conferences with Hitler, nuclear fission comes up only once, and then is mentioned with extreme brevity. Hitler did sometimes comment on its prospects, but what I told him of my conference with the physicists confirmed his view that there was not much profit in the matter. Actually, Professor Heisenberg had not given any final answer to my question whether a successful nuclear fission could be kept under control with absolute certainty or might continue as a chain reaction. Hitler was plainly not delighted with the possibility that the earth under his rule might be transformed into a glowing star. Occasionally, however, he joked that the scientists in their unworldly urge to lay bare all the secrets under heaven might someday set the globe on fire. But undoubtedly a good deal of time would pass before that came about, Hitler said; he would certainly not live to see it.

I am sure that Hitler would not have hesitated for a moment to employ atom bombs against England. I remember his reaction to the final scene of a newsreel on the bombing of Warsaw in the autumn of 1939. We were sitting with him and Goebbels in his Berlin salon watching the film. Clouds of smoke darkened the sky; dive bombers tilted and hurtled toward their goal; we could watch the flight of the released bombs, the pull-out of the planes and the cloud from the explosions expanding gigantically. The effect was enhanced by running the film in slow motion. Hitler was fascinated. The film ended with a montage showing a plane diving toward the outlines of the British Isles. A burst of flame followed, and the island flew into the air in tatters. Hitler's enthusiasm was unbounded. "That is what will happen to them!" he cried out, carried away. "That is how we will annihilate them!"

On the suggestion of the nuclear physicists we scuttled the project to develop an atom bomb by the autumn of 1942, after I had again queried them about deadlines and been told that we could not count on anything for three or four years. The war would certainly have been decided long before then. Instead I authorized the development of an energy-producing uranium motor for propelling machinery. The navy was interested in that for its submarines.

In the course of a visit to the Krupp Works I asked to be shown parts of our first cyclotron and asked the technician in charge whether we could not go on and build a considerably larger apparatus. But he confirmed what Professor Heisenberg had previously said: We lacked the technical experience. At Heidelberg in the summer of 1944, I was shown our first cyclotron splitting an atomic nucleus. To my questions, Professor Walther Bothe explained that this cyclotron would be useful for medical and biological research. I had to rest content with that.

In the summer of 1943, wolframite imports from Portugal were cut off, which created a critical situation for the production of solid-core ammunition. I thereupon ordered the use of uranium cores for this type of ammunition.[27] My release of our uranium stocks of about twelve hundred metric tons showed that we no longer had any thought of producing atom bombs.

Perhaps it would have proved possible to have the atom bomb ready for employment in 1945. But it would have meant mobilizing all our technical and financial resources to that end, as well as our scientific talent. It would have meant giving up all other projects, such as the development of the rocket weapons. From this point of view, too, Peenemünde was not only our biggest but our most misguided project.*

Our failure to pursue the possibilities of atomic warfare can be partly traced to ideological reasons. Hitler had great respect for Philipp Lenard, the physicist who had received the Nobel Prize in 1920 and was one of the few early adherents of Nazism among the ranks of the scientists. Lenard had instilled the idea in Hitler that the Jews were exerting a seditious influence in their concern with nuclear physics and the relativity theory.**

To his table companions Hitler occasionally referred to nuclear physics as "Jewish physics"—citing Lenard as his authority for this. This view was taken up by Rosenberg. It thus becomes clearer why the Minister of Education was not inclined to support nuclear research.

But even if Hitler had not had this prejudice against nuclear research and even if the state of our fundamental research in June 1942 could have freed several billion instead of several million marks for the production of atom bombs, it would have been impossible—given the strain on our economic resources—to have provided the materials, priorities, and technical workers corresponding to such an investment. For it was not only superior productive capacity that allowed the United States to undertake this gigantic project. The increasing air raids had long since created an armaments emergency in Germany which ruled out any such ambitious enterprise. At best, with extreme concentration of all our resources, we could have had a German atom bomb by 1947, but certainly we could not beat the Americans, whose bomb was ready by August 1945.

23. *Office Journal*, May 6, 1942.

24. *Office Journal*, 1942: "On June 4 the Minister flew back to Berlin. . . . That evening there was a lecture in Harnack House on atom-smashing and the development of the uranium machine [sic] and the cyclotron."

25. As late as December 19, 1944, I wrote to Professor Gerlach, who had been placed in charge of the uranium project: "You can always count on me to help you overcome any obstacles that may interfere with your work. Despite the very heavy drain on the labor force by the armaments industry, the relatively small [!] needs of your project can still be met."

26. *Führerprotokoll*, June 23, 1942, Point 15, states only: "Reported briefly to the Fuehrer on the conference on splitting the atom and on the backing we have given the project."

27. *Office Journal*, August 31, 1942, and March 1944. In 1940 twelve hundred metric tons of uranium ore had been seized in Belgium. Mining of domestic ore in Joachimstal was not pushed with any real urgency.

$*$ From 1937 to 1940 the army spent five hundred and fifty million marks on the development of a large rocket. But success was out of the question, for Hitler's principle of scattering responsibility meant that even scientific research teams were divided and often at odds with one another. According to the *Office Journal*, August 17, 1944, not only the three branches of the armed forces but also other organizations, the SS, the postal system, and such, had separate research facilities. In the United States, on the other hand, all the atomic physicists—to take an example—were in one organization.

$**$ According to L. W. Helwig, *Persönlichkeiten der Gegenwart* (1940), Lenard inveighed against "relativity theories produced by alien minds." In his four-volume work, *Die Deutsche Physik* (1935), Helwig considered physics "cleansed of the outgrowths which the by now well-known findings of race research have shown to be the exclusive products of the Jewish mind and which the German *Volk* must shun as racially incompatible with itself."

[In the above passage, Albert Speer made numerous claims about the German nuclear program that have been uncritically accepted and repeated by many historians, journalists, and members of the public in the decades since then. There is clear evidence that Speer's claims were false, and even that he knew they were false. For example:

Speer falsely claimed:	**In fact:**
"Dr. Albert Vögler... called my attention at this time to the neglected field of nuclear research... On May 6, 1942, I discussed this situation with Hitler and proposed that Goering be placed at the head of the Reich Research Council—thus emphasizing its importance."	Far from being neglected, German nuclear weapons research had been going strong since the late 1930s (e.g., pp. 3362–4389). Speer's claim that the nuclear program did not begin until 1942 also contradicts his own claim that the program *ended* in 1942 (see below).
Any German nuclear work, or any information on nuclear work, other than that by Heisenberg was "unreliable," "incompetent," and characterized by "amateurishness."	After the war, Heisenberg remained in (West) Germany and did not do any significant nuclear work, but many hundreds of what Speer called "unreliable," "incompetent," and "amateurish" former German nuclear scientists helped the Soviet Union, France, United Kingdom, United States, and other countries design and build nuclear weapons (Sections 8.7, 8.9, and D.14, plus pp. 2061–2074, 4268–4269).
"[T]he possibility of an atom bomb... quite obviously strained [Hitler's] intellectual capacity. He was also unable to grasp the revolutionary nature of nuclear physics."	Quotes from many independent sources and even photographs prove that Hitler was very supportive of nuclear weapons development and had high hopes for its applications in the war (e.g., pp. 3877–3879, 4575–4576, 4591, 4594, 4634, 4635–4639, 4640–4664, 4667, 4670). There are also many other sources demonstrating strong support and expectations for the nuclear program from the German government (e.g., Section D.13).
"Our failure to pursue the possibilities of atomic warfare can be partly traced to ideological reasons... Hitler occasionally referred to nuclear physics as 'Jewish physics'... Hitler... had this prejudice against nuclear research."	
"Hitler would not have hesitated for a moment to employ atom bombs against England" if he had possessed them; thus the fact that he did not supposedly proves Germany did not have any atom bombs.	Allied leaders publicly and repeatedly threatened to use their own weapons of mass destruction (mustard, phosgene, anthrax, etc.) against Germany if Germany used any form of weapons of mass destruction, which effectively deterred the use of German nuclear weapons through the end of the war in Europe (e.g., pp. 2632–2651, 3786–3791, 4668–4670).
"We scuttled the project to develop an atom bomb by the autumn of 1942."	The German nuclear weapons program continued at full speed from 1942 to the end of the war (e.g., pp. 3998, 4390–5081). Speer's claim that the program ended in 1942 contradicts his own claim that it began in 1942 (see above).

Speer falsely claimed:	**In fact:**
“Instead I authorized the development of an energy-producing uranium motor for propelling machinery.”	Wartime programs to develop nuclear propulsion for submarines, aircraft, and rockets existed, but those programs were not directed by Speer (e.g., pp. 1474, 5757–5771).
“We lacked the technical experience. At Heidelberg in the summer of 1944, I was shown our first cyclotron splitting an atomic nucleus.”	Germany had been designing and building particle accelerators since the 1920s, and it built and used many accelerators throughout the war (Sections C.1, D.6; pp. 4504–4510).
“In the summer of 1943... I thereupon ordered the use of uranium cores for this type of [conventional] ammunition. My release of our uranium stocks of about twelve hundred metric tons showed that we no longer had any thought of producing atom bombs.”	Clearly Speer did not send the 1200 tons of uranium stocks off to be made into ammunition in the summer of 1943, since that 1200 tons of uranium was found in 1945 (e.g., p. 3457) and battlefields littered with German uranium bullets were not found.
“[I]t would have been impossible—given the strain on our economic resources—to have provided the materials, priorities, and technical workers corresponding to such an investment. For it was not only superior productive capacity that allowed the United States to undertake this gigantic project.” “[T]o have the atom bomb ready for employment... would have meant mobilizing all our technical and financial resources to that end, as well as our scientific talent. It would have meant giving up all other projects, such as the development of the rocket weapons.”	If much smaller and poorer nations have been able to successfully develop nuclear weapons, then the industrial power of almost all of Europe under German control certainly could have done so. Indeed, at sites all over Europe, Germany was mining and processing uranium (Sections D.3, D.4) and producing enormous quantities of other nuclear-related materials (Section D.7). Europe had sufficient population, industry, and resources to perform those plus all the other wartime tasks, just as the United States did (though German-controlled Europe could not outcompete the U.S. plus the British Empire plus the Soviet Union for sheer numbers).
“The increasing air raids had long since created an armaments emergency in Germany which ruled out any such ambitious enterprise.”	The German nuclear weapons program began long before Allied bombing (e.g., pp. 3364–3403). For protection against Allied bombing later in the war, German industries were divided among a large number of sites, many of which were underground and/or in the east, which allowed them to continue effectively (e.g., pp. 2075–2076). Likewise the German nuclear weapons program was divided among a large number of sites, many of which were underground and/or in the east (e.g., pp. 4400–4403).

Speer falsely claimed:	**In fact:**
"Mining of domestic [uranium] ore in Joachimstal was not pushed with any real urgency."	Based on postwar inspections, 1946 U.S. intelligence reports on the Joachimstal uranium mine stated: "The Germans put mining on a high priority and only mining was done throughout the 6 years occupation. The ore was delivered by special planes to Germany and Austria" (p. 3998). "The Germans continued operations in this mine to the very last moment" (p. 4981). Germany was also actively mining uranium at many other sites from Portugal to Bulgaria (Section D.3).
"Hitler's principle of scattering responsibility meant that even scientific research teams were divided and often at odds with one another. According to the Office Journal, August 17, 1944, not only the three branches of the armed forces but also other organizations, the SS, the postal system, and such, had separate research facilities. In the United States, on the other hand, all the atomic physicists—to take an example—were in one organization."	The different parts of the German nuclear weapons program were coordinated with each other at the highest levels by the SS (e.g., pp. 3378–3403, 4914–4961, 4998–4999). The compartmentalization of the program made it more resistant to Allied intelligence, sabotage, and bombing.
In different parts of this passage, Speer claimed that Germany could have created an atom bomb as early as 1945, no earlier than 1947, or not at all.	Speer was making so many false statements that he could not even keep them consistent from one page to the next. According to numerous other sources, Germany appears to have successfully created and tested atomic bombs by 1944 (Sections D.10 and D.11).

Although Speer was not in charge of the German nuclear weapons program, he was in sufficiently close communication with those who were to know that his above statements were false (e.g., pp. 3350, 4458, 4593, 4616–4617, 4640–4664, 4938, 5322, 5343).

Thus the evidence presented throughout Appendix D demonstrates that Speer made a whole series of false claims about the German nuclear program just within this short passage. In several cases, what Speer wrote in one paragraph completely contradicted what he had written in another paragraph in this book, or in his other writings (e.g., pp. 4593, 4931).

Beyond the German nuclear program, other researchers have already documented Albert Speer's dishonesty about all sorts of personal and historical events [see for example: Kitchen 2015; Van Der Vat 1997]. The history books of the world should not be founded upon the postwar claims of Speer, a clearly proven serial fabulist. Anything he said should be viewed with extreme skepticism and compared very closely with more trustworthy sources.]

Paul Lawrence Rose. 1998. *Heisenberg and the Nazi Atomic Bomb Project: A Study in German Culture*. Berkeley, California: University of California Press. pp. xvi–xvii.

Since the war an apologetic campaign has been mounted by Heisenberg and other German physicists and historians to demonstrate that he understood fully both the moral and scientific issues involved in this work as chief physicist for the Nazi atomic bomb project from 1939 to 1945. [...] If we are to understand Heisenberg as he really was, we must enter into the German frame of mind, or mentality, or mind-set and sensibility, that had evolved out of the German culture of the nineteenth and twentieth centuries, strange though that mentality appears now to non-Germans, and even to those Germans who have been shaped by the changed and Westernized German culture that has been developing since 1945.

I cannot say that my British background has made me entirely sympathetic to German culture. Although I would be the first to admit its outstanding achievements in science, music, and intellectual life in general, its insistent abstraction as well as the more sinister traditions that accompanied it induce in me a certain skepticism and even aversion. As the American liberal philosopher John Dewey once observed, even Kant's categorical imperative has a whiff of the Prussian drill sergeant about it; the grand moral principle depended, despite its apparent universal reasonableness, on an all too German demand for conforming obedience. Some readers may be put off by what seems, following this spirit of distrust of Kant, the *Tendenz* of the present book, its lack of sympathy with German culture, and its seeming moral and scientific denigration of a great physicist who found himself born into an evil time. [...] The only real test of the historical truth of the present reconstruction is whether it makes better sense of the central problem of the Heisenberg affair and conforms more exactly to the facts as far as we may know them about Heisenberg, the German atomic bomb project, and German culture and society before, during, and after the Third Reich than do other versions. [...]

In this book I have tried to penetrate into how Germans think—or rather, perhaps, used to think—and to show how radically different are German and what I have termed "Western" mentalities and sensibilities. My regret is that in order to expose the nature and fallacies of much of this German thinking and feeling, I have, I fear, often been forced to be tediously analytical. This is not, in consequence, a graceful book, I am sorry to confess, but perhaps Heisenberg and his company have benefited too long from grace of various sorts.

[Such statements from the "expert historians" of this field should spur modern scholars to set aside this conventional historical narrative and make a *de novo*, detailed, and fully independent evaluation of the wartime German nuclear program. The rest of this appendix attempts to do just that, and also to offer leads for future scholars who would like to investigate this subject in further detail.]

D.2 Fundamental Scientific Knowledge and Program Planning

[Beginning in 1939, scientists such as Kurt Diebner (German, 1905–1964), Siegfried Flügge (German, 1912–1997), Paul Harteck (Austrian, 1902–1985), Fritz Houtermans (German, 1903–1966), Josef Schintlmeister (Austrian, 1908–1971), Georg Stetter (Austrian, 1895–1988), and Carl Friedrich von Weizsäcker (German, 1912–2007) gave detailed descriptions of how fission fuel could be used to create either reactors or bombs. They received support from the German government in 1939 and began ambitious programs to create fission reactors and bombs. During 1939–1942, the programs were coordinated by the German army. During 1942–1945, the programs were coordinated by the SS.

For early scientific knowledge regarding the breeding of fission fuel, see Section D.5.1.

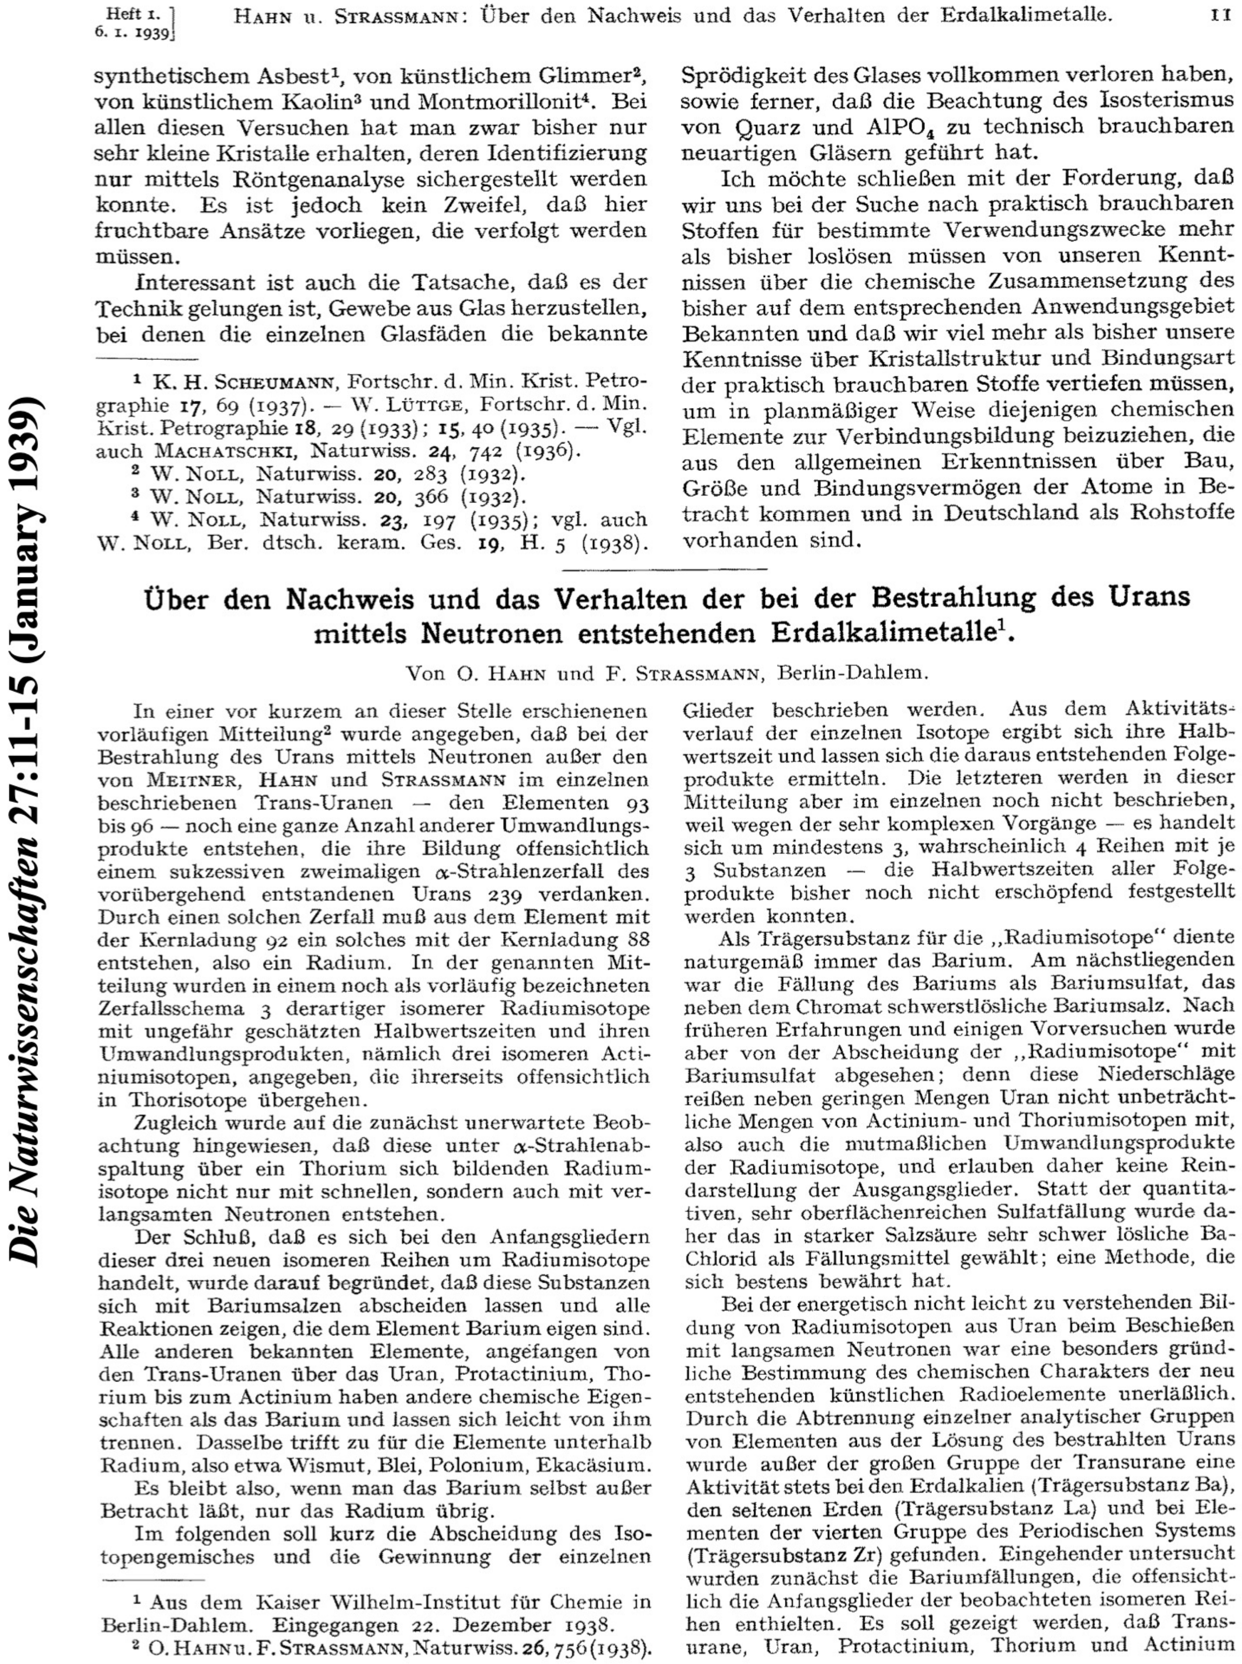
For an organization chart and some key personnel from the programs, see pp. 1568, 1611–1629.]

Otto Hahn and Fritz Strassmann. January 1939. Über den Nachweis und das Verhalten der bei der Bestrahlung des Urans mittels Neutronen entstehenden Erdalkalimetalle. [About the Detection and Behavior of the Alkaline Earth Metals Formed During the Irradiation of Uranium with Neutrons.] ***Die Naturwissenschaften*** **27:11–15.**

[...] Bei der energetisch nicht leicht zu verstehenden Bildung von Radiumisotopen aus Uran beim Beschießen mit langsamen Neutronen war eine besonders gründliche Bestimmung des chemischen Charakters der neu entstehenden künstlichen Radioelemente unerläßlich. Durch die Abtrennung einzelner analytischer Gruppen von Elementen aus der Lösung des bestrahlten Urans wurde außer der großen Gruppe der Transurane eine Aktivität stets bei den Erdalkalien (Trägersubstanz Ba), den seltenen Erden (Trägersubstanz La) und bei Elementen der vierten Gruppe des Periodischen Systems (Trägersubstanz Zr) gefunden. Eingehender untersucht wurden zunächst die Bariumfällungen, die offensichtlich die Anfangsglieder der beobachteten isomeren Reihen enthielten. Es soll gezeigt werden, daß Transurane, Uran, Protactinium, Thorium und Actinium sich stets leicht und vollständig von der mit Barium ausfallenden Aktivität trennen lassen. [...]

[...] Since it is not easy to understand from energy considerations how radium isotopes can be produced when uranium is bombarded with slow neutrons, a very careful determination of the chemical properties of the new artificially made radioelements was necessary. Various analytic groups of elements were separated from a solution containing the irradiated uranium. Besides the large group of transuranic elements, some radioactivity was always found in the alkaline-earth group (barium carrier), the rare-earth group (lanthanum carrier), and also with elements in group IV of the periodic table (zirconium carrier). The barium precipitate was the first to be investigated more thoroughly, since it apparently contains the parent isotopes of the observed isomeric series. The goal was to show that the transuranic elements, and also uranium, protactinium, thorium, and actinium could always be separated easily and completely from the activity which precipitates with barium. [...]

[At the Kaiser Wilhelm Institute for Chemistry in Berlin-Dahlem, Hahn and Strassmann discovered neutron-induced fission of uranium into lighter elements in 1938, and published their results in January 1939.]



Die Naturwissenschaften **27:11-15 (January 1939)**

synthetischem Asbest[1], von künstlichem Glimmer[2], von künstlichem Kaolin[3] und Montmorillonit[4]. Bei allen diesen Versuchen hat man zwar bisher nur sehr kleine Kristalle erhalten, deren Identifizierung nur mittels Röntgenanalyse sichergestellt werden konnte. Es ist jedoch kein Zweifel, daß hier fruchtbare Ansätze vorliegen, die verfolgt werden müssen.

Interessant ist auch die Tatsache, daß es der Technik gelungen ist, Gewebe aus Glas herzustellen, bei denen die einzelnen Glasfäden die bekannte Sprödigkeit des Glases vollkommen verloren haben, sowie ferner, daß die Beachtung des Isosterismus von Quarz und $AlPO_4$ zu technisch brauchbaren neuartigen Gläsern geführt hat.

Ich möchte schließen mit der Forderung, daß wir uns bei der Suche nach praktisch brauchbaren Stoffen für bestimmte Verwendungszwecke mehr als bisher loslösen müssen von unseren Kenntnissen über die chemische Zusammensetzung des bisher auf dem entsprechenden Anwendungsgebiet Bekannten und daß wir viel mehr als bisher unsere Kenntnisse über Kristallstruktur und Bindungsart der praktisch brauchbaren Stoffe vertiefen müssen, um in planmäßiger Weise diejenigen chemischen Elemente zur Verbindungsbildung beizuziehen, die aus den allgemeinen Erkenntnissen über Bau, Größe und Bindungsvermögen der Atome in Betracht kommen und in Deutschland als Rohstoffe vorhanden sind.

Über den Nachweis und das Verhalten der bei der Bestrahlung des Urans mittels Neutronen entstehenden Erdalkalimetalle[1].

Von O. HAHN und F. STRASSMANN, Berlin-Dahlem.

In einer vor kurzem an dieser Stelle erschienenen vorläufigen Mitteilung[2] wurde angegeben, daß bei der Bestrahlung des Urans mittels Neutronen außer den von MEITNER, HAHN und STRASSMANN im einzelnen beschriebenen Trans-Uranen — den Elementen 93 bis 96 — noch eine ganze Anzahl anderer Umwandlungsprodukte entstehen, die ihre Bildung offensichtlich einem sukzessiven zweimaligen α-Strahlenzerfall des vorübergehend entstandenen Urans 239 verdanken. Durch einen solchen Zerfall muß aus dem Element mit der Kernladung 92 ein solches mit der Kernladung 88 entstehen, also ein Radium. In der genannten Mitteilung wurden in einem noch als vorläufig bezeichneten Zerfallsschema 3 derartiger isomerer Radiumisotope mit ungefähr geschätzten Halbwertszeiten und ihren Umwandlungsprodukten, nämlich drei isomeren Actiniumisotopen, angegeben, die ihrerseits offensichtlich in Thorisotope übergehen.

Zugleich wurde auf die zunächst unerwartete Beobachtung hingewiesen, daß diese unter α-Strahlenabspaltung über ein Thorium sich bildenden Radiumisotope nicht nur mit schnellen, sondern auch mit verlangsamten Neutronen entstehen.

Der Schluß, daß es sich bei den Anfangsgliedern dieser drei neuen isomeren Reihen um Radiumisotope handelt, wurde darauf begründet, daß diese Substanzen sich mit Bariumsalzen abscheiden lassen und alle Reaktionen zeigen, die dem Element Barium eigen sind. Alle anderen bekannten Elemente, angefangen von den Trans-Uranen über das Uran, Protactinium, Thorium bis zum Actinium haben andere chemische Eigenschaften als das Barium und lassen sich leicht von ihm trennen. Dasselbe trifft zu für die Elemente unterhalb Radium, also etwa Wismut, Blei, Polonium, Ekacäsium.

Es bleibt also, wenn man das Barium selbst außer Betracht läßt, nur das Radium übrig.

Im folgenden soll kurz die Abscheidung des Isotopengemisches und die Gewinnung der einzelnen Glieder beschrieben werden. Aus dem Aktivitätsverlauf der einzelnen Isotope ergibt sich ihre Halbwertszeit und lassen sich die daraus entstehenden Folgeprodukte ermitteln. Die letzteren werden in dieser Mitteilung aber im einzelnen noch nicht beschrieben, weil wegen der sehr komplexen Vorgänge — es handelt sich um mindestens 3, wahrscheinlich 4 Reihen mit je 3 Substanzen — die Halbwertszeiten aller Folgeprodukte bisher noch nicht erschöpfend festgestellt werden konnten.

Als Trägersubstanz für die „Radiumisotope" diente naturgemäß immer das Barium. Am nächstliegenden war die Fällung des Bariums als Bariumsulfat, das neben dem Chromat schwerstlösliche Bariumsalz. Nach früheren Erfahrungen und einigen Vorversuchen wurde aber von der Abscheidung der „Radiumisotope" mit Bariumsulfat abgesehen; denn diese Niederschläge reißen neben geringen Mengen Uran nicht unbeträchtliche Mengen von Actinium- und Thoriumisotopen mit, also auch die mutmaßlichen Umwandlungsprodukte der Radiumisotope, und erlauben daher keine Reindarstellung der Ausgangsglieder. Statt der quantitativen, sehr oberflächenreichen Sulfatfällung wurde daher das in starker Salzsäure sehr schwer lösliche Ba-Chlorid als Fällungsmittel gewählt; eine Methode, die sich bestens bewährt hat.

Bei der energetisch nicht leicht zu verstehenden Bildung von Radiumisotopen aus Uran beim Beschießen mit langsamen Neutronen war eine besonders gründliche Bestimmung des chemischen Charakters der neu entstehenden künstlichen Radioelemente unerläßlich. Durch die Abtrennung einzelner analytischer Gruppen von Elementen aus der Lösung des bestrahlten Urans wurde außer der großen Gruppe der Transurane eine Aktivität stets bei den Erdalkalien (Trägersubstanz Ba), den seltenen Erden (Trägersubstanz La) und bei Elementen der vierten Gruppe des Periodischen Systems (Trägersubstanz Zr) gefunden. Eingehender untersucht wurden zunächst die Bariumfällungen, die offensichtlich die Anfangsglieder der beobachteten isomeren Reihen enthielten. Es soll gezeigt werden, daß Transurane, Uran, Protactinium, Thorium und Actinium

TO: Major R. R. Furman

FROM: Dr. S. A. Goudsmit

1. The Harteck file of correspondence with the RFR contains one very interesting document at the end. It is a proposal which was sent by Harteck and Groth to the War Ministry on 24 April 1939. In this letter, they write roughly:

> "We take the liberty of calling to your attention the newest developments in nuclear physics which, in our opinion, will perhaps make it possible to produce an explosive which is many orders of magnitude more effective than the present one."

2. They then give a short popular account of the discovery of Hahn and the work of Joliot and mention that, in America and in England, great emphasis is placed on research in nuclear physics, whereas the same subject has been neglected in Germany.

3. They finish the letter with the following paragraph:

> "It is obvious that, if the possibility of energy production outlined above can be realized, which certainly is within the realm of possibilities, that country which first makes use of it has an unsurpassable advantage over the others."

Siegfried Flügge. Kann der Energieinhalt der Atomkerne technisch nutzbar gemacht werden? [Can the Energy Content of Atomic Nuclei Be Made Technically Usable?] *Die Naturwissenschaften* 27:23/24:402–410. 9 June 1939. [For consistency, all numbers on this page use U.S. decimal points in place of German commas.]

[...] Als Beispiel betrachten wir zunächst die Verhältnisse an reinem Uranmetall. Für schnelle Neutronen besteht kein merkbarer Einfangquerschnitt; wir haben außer $\sigma_{Sp} = 0.1 \cdot 10^{-24}$ cm^2 nur noch Streuprozesse mit rund $6 \cdot 10^{-24}$ cm^2. Metallisches Uran (Dichte 18.6) enthält rund $2.2 \cdot 10^{22}$ Atome je Kubikzentimeter; es wird dann bei einer Neutronengeschwindigkeit von $2 \cdot 10^9$ cm/sec, entsprechend einer mittleren Energie der frei gesetzten Neutronen von 2 MeV:

[...] As an example, we consider the relations for pure uranium metal. For fast neutrons there is no significant capture cross-section; we have outside of [the fission cross section] $\sigma_{Sp} = 0.1 \cdot 10^{-24}$ cm^2 only scattering processes with around $6 \cdot 10^{-24}$ cm^2. Metallic uranium (density 18.6) contains around $2.2 \cdot 10^{22}$ atoms per cubic centimeter; there will be then, at a neutron velocity of $2 \cdot 10^9$ cm/sec, corresponding to a mean energy of released neutrons of 2 MeV [ν is the number of neutrons released per fission]:

$$\frac{1}{n}\frac{dn}{dt} = 0.44\,(\nu - 1) \cdot 10^7 \quad \mathrm{sec}^{-1} .$$

Die Integration dieser Differentialgleichung ergibt

The integration of this differential equation yields

$$n(t) = n_0\, e^{0.44(\nu-1)\cdot 10^7 t} .$$

Läßt man die Reaktionskette mit $n_0 = 1$ Neutron zur Zeit $t = 0$ anlaufen und nimmt man den wahrscheinlichsten Wert $\nu = 2$, so findet man, da je Spaltung $3 \cdot 10^{-12}$ mkg frei werden, folgende Energiebeträge: Nach 10^{-7} sec: $4.7 \cdot 10^{-12}$ mkg, nach 10^{-6} sec: $2.4 \cdot 10^{-11}$ mkg, nach 10^{-5} sec: $3 \cdot 10^{+7}$ mkg und nach 10^{-4} sec: $3 \cdot 10^{+78}$ mkg. Die letzte Zahl hat natürlich keinen Sinn mehr; sie bedeutet nur, daß in weniger als 10^{-4} sec das gesamte Uran umgesetzt wird. Die Energiebefreiung geschieht also in einer so kurzen Zeit, daß wir es mit einer außerordentlich heftigen Explosion zu tun haben. [...]

If the reaction chain is started with $n_0 = 1$ neutron at time $t = 0$ and if the most probable value is $\nu = 2$, then one finds, if each fission releases $3 \cdot 10^{-12}$ mkg [9.8 Joules per meter-kilogram], the following energy amounts: After 10^{-7} sec: $4.7 \cdot 10^{-12}$ mkg, after 10^{-6} sec: $2.4 \cdot 10^{-11}$ mkg, after 10^{-5} sec: $3 \cdot 10^{+7}$ mkg and after 10^{-4} sec: $3 \cdot 10^{+78}$ mkg. The last number naturally has no more meaning; it only means that in less than 10^{-4} sec, the entire uranium is converted. The energy release happens in such a short time that we are dealing with an extraordinarily violent explosion. [...]

[Siegfried Flügge (German, 1912–1997) was a nuclear physicist at the Kaiser Wilhelm Institute for Chemistry. In this article, he explicitly showed the feasibility of using pure uranium fuel and fast neutrons to create an explosive chain reaction, estimating both the time scale and energy release for the explosion. Elsewhere in the article, he explicitly proposed water-moderated fission power reactors using thermal neutrons, derived and used the neutron diffusion and kinetics equations that are still taught in modern nuclear engineering textbooks, and correctly stated that cadmium could be used as a neutron absorber to maintain control of the neutron-induced fission reactions. A popularized version of this *Naturwissenschaften* article was published: Siegfried Flügge. Die Ausnutzung der Atomenergie. Vom Laboratoriumsversuch zur Uranmaschine—Forschungsergebnisse in Dahlem. *Deutsche Allgemeine Zeitung* No. 387, Supplement. 15 August 1939. [English translation in Hentschel and Hentschel 1996, pp. 197–206]. Flügge subsequently moved to the Reichspost, where he apparently played a key role in the wartime German nuclear program (pp. 3608, 4996).]

Kann der Energieinhalt der Atomkerne technisch nutzbar gemacht werden?

Von S. FLÜGGE, Berlin-Dahlem*.

UNCLASSIFIED

Zu Beginn dieses Jahres entdeckten HAHN und STRASSMANN[1], daß beim Beschießen von Uran mit schnellen oder langsamen Neutronen Barium, Lanthan und andere Elemente mittleren Atomgewichts entstehen. Die Entdeckung wurde sofort von zahlreichen Forschern in vielen Ländern aufgegriffen, und eine intensive Arbeit auf diesem Gebiet hat den Sachverhalt weitgehend geklärt und in mehr als 50 Veröffentlichungen schon zahlreiches quantitatives Material ergeben.

Im folgenden soll nur über ein Teilgebiet des ganzen, durch die HAHN-STRASSMANNsche Entdeckung angeschnittenen Fragenkomplexes berichtet werden. Gleich nachdem die Entdeckung der Zerspaltung von Urankernen sichergestellt war, wurde im HAHNschen Institut und wohl auch anderwärts die Frage aufgeworfen, ob bei einem so gewaltsamen Eingriff nicht auch einige Neutronen aus dem zerbrechenden Kern „abgedampft" oder „abgesplittert" werden könnten? Die Frage wurde auch alsbald in Angriff genommen, da sie zu einer sehr interessanten Konsequenz führte: Wenn jedes Neutron, das eine Aufspaltung hervorruft, im Gefolge der Aufspaltung 2 oder 3 Neutronen frei macht, so muß es möglich sein, daß diese Neutronen ihrerseits wiederum neue Aufspaltungen anderer Urankerne herbeiführen und auf diese Weise ihre Zahl noch weiter vergrößert wird, so daß eine Kettenreaktion ohne Ende schließlich zu einer Umsetzung des ganzen in dem bestrahlten Präparat vorhandenen Urans führen kann.

Man konnte dazu sofort einige Überlegungen anstellen, noch ehe man Einzelheiten kannte: Die Hauptfrage ist natürlich, ob und wie viele Neutronen je Spaltungsprozeß in Freiheit gesetzt werden. Dann kommt alles auf das weitere Schicksal dieser Neutronen an. Sie werden elastische Stöße ausführen können, die im wesentlichen nur ihre Richtung ändern; sie können unelastisch gestreut werden, so daß sie außer der Richtungsänderung auch noch eine beträchtliche Energieeinbuße erleiden; sie können eingefangen werden in der bekannten Reaktion

$$ {}^{238}_{92}\mathrm{U} + {}^{1}_{0}n \longrightarrow {}^{239}_{92}\mathrm{U}^{*} \xrightarrow[23\,\mathrm{m}]{\beta} {}^{239}_{93}\mathrm{Eka\text{-}Re}; \qquad (1) $$

sie können endlich noch Einfangungen oder Umwandlungen an anderen Substanzen erleiden, die außer dem Uran anwesend sind, sofern man nicht reines Uranmetall bestrahlt, also z. B. am Sauerstoff von U_3O_8. Es wird darauf ankommen, ob all diese Reaktionen, welche nur Neutronen wegfangen ohne neue zu erzeugen, einen so großen Gesamtwirkungsquerschnitt haben, daß die beim Spaltungsprozeß erreichte Neutronenproduktion dadurch kompensiert wird oder nicht. Um zu erkennen, ob eine Kettenreaktion ablaufen kann, müssen wir also über eine genaue Kenntnis aller konkurrierenden Wirkungsquerschnitte verfügen.

Endlich spielt noch eine dritte Frage eine große Rolle: die räumliche Ausdehnung der bestrahlten Substanzmenge. Die erzeugten Neutronen werden, ehe sie wieder einen Kern aufspalten, einen Weg von der Größenordnung einiger Zentimeter in der Substanz zurücklegen. Läuft also die Reaktionskette an einer Stelle der Substanz an, so breitet sie sich mit zunehmender Neutronenzahl über ein immer größeres Gebiet aus. Nun haben die Neutronen bei jedem elastischen Stoß die gleiche Chance zurückgeworfen zu werden, wie weiter nach außen zu laufen. Daher wird die Konzentration der freigesetzten Neutronen auch an der Ausgangsstelle der Reaktionskette zeitlich rasch ansteigen, sofern das benutzte Substanzvolumen so groß ist, daß der größte Teil der Neutronen oft zurückgeworfen wird, ohne die Oberfläche zu erreichen, durch die er die Substanz endgültig verlassen würde. Mit anderen Worten: Der Durchmesser einer bestrahlten Kugel aus uranhaltiger Substanz muß groß sein gegen die freie Weglänge, wird also einige Meter betragen müssen.

Ehe wir zur Diskussion der bisher angeschnittenen Einzelfragen übergehen, soll noch ein Wort gesagt werden über die Größenordnung der freiwerdenden Energie. Man kann sie leicht ungefähr abschätzen[2], ja sogar ziemlich genau angeben, daß jeder Spaltungsprozeß eine Energie von 180 MeV in Freiheit setzt[3]. Das läßt sich aus der Differenz der Massendefekte des Urankerns und der entstehenden Spaltungsprodukte herleiten[3]; die Zahl ist einigermaßen auch durch direkte Messung der kinetischen Energie der beiden entstehenden mittelschweren Kerne experimentell sichergestellt. Daß sich hierbei statt der erwarteten 180 MeV nur rund 160 MeV ergaben[4], kann schon als Hinweis darauf dienen, daß der Rest der Energie entweder noch in abgespaltene Neutronen gesteckt oder in Form von γ-Quanten abgestrahlt wird.

Der so erhaltene Energiebetrag ist sehr beträchtlich. Da die vorstehenden Überlegungen zeigen, daß es durchaus nicht ausgeschlossen ist, durch eine geeignete Versuchsanordnung eine Reaktionskette hervorzurufen, bei der das ganze Uran eines großen Blocks verbraucht wird, ist es zweckmäßig, sich einmal auszurechnen, wie groß z. B. die Energiemenge ist, die freigesezt wird, wenn in 1 m^3 U_3O_8 alles vorhandene Uran restlos umgewandelt wird. 1 m^3 aufgeschüttetes U_3O_8-Pulver wiegt 4,2 t und enthält $3 \cdot 10^{27}$ Moleküle, also $9 \cdot 10^{27}$ Uranatome. Da je Atom etwa 180 MeV, d. h. rund $3 \cdot 10^{-4}$ erg oder $3 \cdot 10^{-12}$ mkg frei werden, wird insgesamt ein Energiebetrag von $27 \cdot 10^{15}$ mkg frei gesetzt, d. h. 1 m^3 U_3O_8 genügt zur Aufbringung der Energie, welche nötig ist, um 1 km^3 Wasser (Gewicht 10^{12} kg) 27 km hoch-

zuheben! Da diese Energie, wie wir noch sehen werden, ohne besondere Vorsichtsmaßregeln in einem Zeitraum von weniger als $^1/_{100}$ sec in Freiheit gesetzt wird, ist die entscheidende Frage für die technische Anwendbarkeit des Reaktionsmechanismus, ob es gelingt, eine hinreichende Verzögerung herbeizuführen, die es ermöglicht, die Geschwindigkeit des Ablaufs nach Belieben zu steuern und herabzudrücken. Da auch zu diesem Punkte heute schon Angaben gemacht werden können, liegt hier wohl zum ersten Male ein Fall vor, bei dem die technische Nutzbarmachung der ungeheuren, in den Atomkernen gebundenen Energiebeträge auch zu technischen Zwecken in greifbare Nähe gerückt ist.

1. Die entstehenden Neutronen. Der Nachweis, daß bei der Uranspaltung Neutronen frei werden, wurde mit voller Sicherheit zuerst von Dodé, v. Halban, Joliot und Kowarski[5] geführt. Eine Neutronenquelle, in der die γ-Strahlen eines Radiumpräparats auf Be einwirken und welche Neutronen von nur einigen 100 keV Energie liefert, wurde umgeben mit einer Schicht von Uranylnitrat $(UO_2)(NO_3)_2 \cdot 6\,H_2O$ in einer Dicke von 10 g/cm². Die ganze Anordnung befand sich im Innern eines großen Gefäßes, daß mit 8 l Schwefelkohlenstoff gefüllt war, in dem 200 mg Phosphor gelöst sind. Nach einer Bestrahlungsdauer von 6 Tagen wurde der Phosphor durch Abdestillieren von dem Schwefelkohlenstoff getrennt und gefunden, daß er eine Aktivität von 35 Teilchen je Minute zeigte. Ein Blindversuch ohne Uran ergab dagegen nur 5 Teilchen je Minute nach achttägiger Bestrahlung. Die Ursache der Aktivität muß in der Reaktion $^{32}_{16}S\,(n,p)\,^{32}_{15}P^*$ gesucht werden; diese Reaktion geht aber erst bei Neutronenenergien von mehr als 900 keV überhaupt vor sich, und so schnelle Neutronen liefert die benutzte Quelle gar nicht. Sie müssen also sekundär im Uran erzeugt worden sein.

Joliot und seine Mitarbeiter sowie Fermi und seine Mitarbeiter haben versucht, quantitativ sichere Angaben über die Zahl der Neutronen zu machen, die frei werden. Die von ihnen benutzte Methode ist die folgende: Befindet sich eine Neutronenquelle im Innern eines großen Wassertanks, so werden die Neutronen durch Zusammenstöße mit den Protonen des Wassers, an die sie je Stoß im Mittel etwa die Hälfte ihrer Energie abgeben, abgebremst bis zu so kleinen Geschwindigkeiten, wie sie dem thermischen Gleichgewicht mit der Substanz entsprechen. Man spricht dann von thermischen Neutronen und erhält bei Messungen mit einem geeigneten Indikator, ziemlich unabhängig von der Art der benutzten Neutronenquelle, eine bestimmte stationäre Dichteverteilung dieser thermischen Neutronen in dem Wassertank, die sich als Gleichgewicht zwischen Diffusion, Absorption durch Einfang an Protonen und Nachlieferung durch die Quelle einstellt und die rechnerisch durch die Lösung dieses etwas komplizierteren Diffusionsproblems erfaßt werden kann[6].

Löst man nun in dem Wasser ein Uransalz, so werden durch Spaltungsprozesse an allen Stellen des Tanks offenbar zusätzlich Neutronen erzeugt, die eine Veränderung der Dichteverteilung hervorrufen. Insbesondere wird der Abfall der Dichte bei großen Abständen von der Quelle etwas langsamer erfolgen, da man der Hauptverteilungskurve mit dem Zentrum am Ort der Neutronenquelle beliebig viele andere überlagern muß mit dem Zentrum an allen anderen Stellen des Wassertanks. Aus dem Vergleich der beiden Verteilungskurven muß es im Prinzip möglich sein, sowohl die Zahl als die Energie der zusätzlichen Neutronen abzuschätzen; die Zahl muß einfach gleich sein dem Unterschiede in den Gesamtzahlen, die man durch Integration der beobachteten Dichte mit und ohne Uransalz über den ganzen Wassertank erhält; der Abfall nach außen wird um so langsamer erfolgen, je höher die Energie der im Uran ausgelösten zusätzlichen Neutronen ist.

Die Abschätzung der Energie auf diesem Wege ist nun praktisch leider so gut wie unmöglich, da infolge der sehr rasch erfolgenden Abbremsung aller entstehenden Neutronen auf thermische Geschwindigkeiten die allein meßbare Dichteverteilung sehr unempfindlich gegen Änderungen in der Energie der entstehenden Teilchen ist. Daher rührt ja auch ihre ziemlich weitgehende Unabhängigkeit von der Art der benutzten Quelle.

Mehr kann man schon über die Zahl der freiwerdenden Neutronen aussagen. Die erste Abschätzung von Joliot und seinen Mitarbeitern[7] ergab einen mittleren Wert von 3,5 Neutronen je Spaltungsprozeß; die angegebene Fehlergrenze von $\pm$ 0,7 scheint aber doch etwas zu eng. Eine zweite Abschätzung unternahmen Fermi und seine Mitarbeiter[8] nach einer ganz ähnlichen Methode, die sich nur dadurch von der Joliotschen unterschied, daß das Uran nicht im Wasser gelöst, sondern in einer Schicht um die Quelle herumgelegt wurde. Sie geben einen Wert von rund 2 Neutronen je Spaltungsprozeß an, der wohl etwas sicherer ist. Abschätzungen von Szilard und Zinn sowie von v. Droste und Reddemann[9] haben diese Größenordnung bestätigt durch unmittelbare Zählung der Helium-Rückstoßkerne, die die Neutronen in einer heliumgefüllten Ionisationskammer auslösen, aber bisher noch nicht gestattet, die Zahl genauer festzulegen. Nimmt man alle diese Erfahrungen zusammen, so darf man als wahrscheinlichsten Wert zur Zeit wohl etwa 2 Neutronen je Spaltungsprozeß ansehen.

Von Hafstad[10] und seinen Mitarbeitern ist behauptet worden, daß auch nach Aufhören der Bestrahlung noch Neutronen aus der Substanz austreten mit einer Halbwertszeit von rund 12 sec, deren Energie durch Rückstoßprotonen in der Nebelkammer zu etwa einer halben MeV bestimmt wurde. Dies Ergebnis konnte bisher von anderen Forschern noch nicht bestätigt werden. Während Hafstad und Mitarbeiter abschätzen, daß rund die Hälfte aller Spaltungsprozesse solche Neutronen erzeugt, gelangten Szilard und Zinn, denen es nicht gelang, die „Nachwirkungsneutronen" überhaupt nachzuweisen, zu der Überzeugung, daß deren Zahl sicher klein ist gegen die der sofort freigemachten Neutronen.

Über die Energie der letzteren liegen Messungen von v. Droste und Reddemann vor, die zeigen, daß mit Sicherheit noch schnellere Neutronen als solche von 2,5 MeV dabei entstehen.

2. Die Wirkungsquerschnitte am Uran. Die Prozesse, die im Uran stattfinden, sind die folgenden:

a) Der Einfangprozeß: Eine Einfangung des Neutrons nach der Reaktionsgleichung (1) kann nachgewiesen werden durch chemische Trennung des Urans von den anderen entstehenden Reaktionsprodukten und Nachweis eines β-Strahlers von 23 min Halbwertszeit, eben des $^{239}_{92}U^*$. Der Prozeß ist ein normaler Einfang, wie er an unzähligen anderen Elementen auch nachgewiesen und untersucht worden ist, mit allen typischen Eigenschaften einer derartigen Kernreaktion: Er wird mit einem meßbaren Wirkungsquerschnitt (WQ.) nur von langsamen Neutronen hervorgerufen, nämlich solchen, deren Energie entweder in eine Resonanzbande bei einigen eV oder in den thermischen Bereich fällt, der sich um eine mittlere Energie $\frac{\pi}{4}kT = 0{,}026$ eV bei Zimmertemperatur gruppiert.

Die Abhängigkeit des WQ von der Energie E oder Geschwindigkeit v der benutzten Neutronen kann, wie bei allen solchen Prozessen, durch die Formel von Breit und Wigner beschrieben werden:

$$\sigma_{\text{Einf}} = \sqrt{\frac{E_r}{E}}\,\sigma_r\,\frac{\left(\frac{\Gamma}{2}\right)^2}{(E-E_r)^2+\left(\frac{\Gamma}{2}\right)^2}; \qquad (2)$$

vorausgesetzt ist dabei lediglich, daß nur ein einziges Resonanzniveau merklich zum Einfang beiträgt, daß also alle weiteren Niveaus in einem Energiebereich liegen, in dem die Neutronenanzahl schon sehr gering ist. Dabei gilt im großen ganzen, daß die Anzahl der Neutronen mit wachsender Energie rasch abnimmt; auf das Intervall dv bei der Geschwindigkeit v entfällt nur ein Bruchteil, der dv/v^3 proportional ist.

Die Konstanten in Gl. (2) haben folgende einfache Bedeutung: E_r ist diejenige Energie, bei der das Resonanzmaximum liegt; der Wert von σ_{Einf} für diese Energie ist σ_r; die Halbwertsbreite der Resonanzlinie ist Γ.

Die Lage der Linie, also E_r, kann man bestimmen, indem man einmal die Absorption thermischer Neutronen der mittleren Energie $E_{\text{th}} = \frac{\pi}{4}kT$, und einmal diejenigen der Resonanzneutronen von Uran in Borschichten mißt. Da der Absorptionsquerschnitt für Neutronen in Bor proportional $1/\sqrt{E}$ ist, verhalten sich die gemessenen Absorptionskoeffizienten wie

$$(\mu_{\text{th}}/\mu_{\text{U}})_{\text{Bor}} = \sqrt{E_r/E_{\text{th}}}\,.$$

Die Messung von μ_{th} geschieht, indem man zwischen Neutronenquelle und Absorber einmal ein einige Millimeter dickes Cd-Blech schaltet und einmal nicht. Da das Cd nur thermische Neutronen absorbiert, und diese quantitativ, gibt die Differenz beider Messungen unmittelbar die Zahl der thermischen Neutronen an. Zur Messung von μ_{U} schaltet man außerdem noch Uranfilter vor, die außer im thermischen Bereich — den man durch Kombinationen mit und ohne Cd wieder abtrennen kann — nur noch in der nächsten Umgebung der Resonanzenergie E_r merklich absorbieren.

Messungen dieser Art sind von Meitner, Hahn und Strassmann durchgeführt[11] und ergaben $E_r = 25$ eVolt.

Zur Bestimmung von σ_r mißt man nach Wegfilterung aller thermischen Neutronen durch Cd die Absorption langsamer Neutronen in Uranschichten unter Benutzung ebenfalls einer Uranschicht als Nachweissubstanz für die Neutronen, die den Uranabsorber durchsetzt haben (Selbstabsorption). Ein solcher Detektor zeigt dann offenbar nur solche Neutronen an, deren Energie in die Resonanzlinie fällt; ihre Absorbierbarkeit wird aber im wesentlichen durch σ_r allein bestimmt. In der Arbeit von Meitner, Hahn und Strassmann wird als mittlerer Absorptionskoeffizient innerhalb der Resonanzlinie rund 3 cm²/g angegeben; für die Mitte der Linie muß man danach etwa das Doppelte dieses Wertes erwarten. Eine genauere Ausführung der Integration über die Resonanzlinie bei Zugrundelegung von Gl. (2) und den experimentellen Zahlen der genannten Arbeit ergibt einen Wert von 7 cm²/g in der Linienmitte in guter Übereinstimmung mit dieser Schätzung. Daraus folgt dann $\sigma_r = 2800 \cdot 10^{-24}$ cm².

Die dritte Größe, die Linienbreite, ist bisher nicht direkt gemessen worden. Da solche Messungen auch nicht ganz leicht sind, ist es zweckmäßig, statt ihrer als dritte Größe den WQ für thermische Neutronen zu messen. Diese Bestimmung wurde von v. Halban und Mitarbeitern[12] jetzt auch ausgeführt. Sie verglichen die Aktivität des aus Uran erhaltenen 23 min-Körper mit derjenigen einer bestrahlten Goldfolie mit und ohne vorgeschaltetes Cd-Filter. Dabei befand sich zwischen Neutronenquelle und Versuchsanordnung stets noch ein Uranfilter und ein Goldfilter, die dafür sorgten, daß die benutzten Neutronen arm waren an denjenigen Energien, die mit einer der beiden Resonanzstellen nahe übereinstimmten, d. h. also, daß sie von vornherein im wesentlichen nur aus thermischen Neutronen bestanden. Da der Einfangquerschnitt von Gold für thermische Neutronen schon früher von Amaldi und Fermi bestimmt wurde, gestattet dieser Vergleich die Eichung auch für den Uranprozeß. Auf diesem Wege ergab sich ein Querschnitt von $(1{,}3 \pm 0{,}5) \cdot 10^{-24}$ cm². Berechnet man hieraus rückwärts die Linienbreite, so findet man $\Gamma = 0{,}2$ eV, einen Wert, der durchaus dem entspricht, was man von den Einfangprozessen an anderen Elementen gewöhnt ist.

b) Der Spaltungsprozeß: Für den Spaltungsprozeß wurden WQ-Messungen von Dunning, Fermi und Mitarbeitern[13] durchgeführt. Zunächst wurde in einer Ionisationskammer, die mit einer so dünnen Schicht von Uranoxyd ausgelegt war, daß alle Trümmer in die Kammer gelangen und gezählt werden konnten, die Anzahl der von einer Standard-Neutronenquelle hervorgerufenen Spaltungsprozesse bestimmt. Durch Abdecken der Neutronenquelle mit Cd konnte der Teilquerschnitt der thermischen Neutronen zu $2 \cdot 10^{-24}$ cm² bestimmt werden. Für die schnellen Neutronen einer Rn + Be-Quelle ergab sich der viel kleinere Querschnitt von $0{,}1 \cdot 10^{-24}$ cm².

Auch über die Abhängigkeit des Wirkungsquerschnitts von der Neutronenenergie wurde bei langsamen Neutronen ein Versuch angestellt. Deckt man nämlich die Neutronenquelle mit immer dickeren Absorptionsfolien aus Bor ab, so werden, da die Absorption der Neutronen in Bor proportional $1/v$ ist, zunächst die langsamsten Neutronen, dann bei dickeren Schichten in zunehmendem Maße auch die schnelleren absorbiert. Es tritt also eine Härtung der Strahlung ein. Exponiert man nun einmal eine Borschicht und das andere Mal eine Uranschicht mit den auf diese Weise gewonnenen verschieden harten Neutronen so bekommt man genau den gleichen Verlauf der Ausbeute mit der Dicke des vorgeschalteten Borfilters. Es muß also, da der WQ im Bor proportional $1/v$ ist, auch der Prozeß für die Spaltungsprozesse in Uran proportional $1/v$ sein. Wir können daher die Formel anschreiben:

$$\sigma_{\text{Spalt}} = 2\sqrt{E_{\text{th}}/E} \cdot 10^{-24}\ \text{cm}^2. \qquad (3)$$

In der gleichzeitigen Gültigkeit der Gleichungen (2) und (3) liegt übrigens eine erhebliche theoretische Schwierigkeit. Eine Formel vom Typus (3) sollte man nämlich nur dann erwarten, wenn die Lebensdauer des beim Einfang entstehenden Zwischenkerns sehr kurz ist, d. h. bei einer sehr starken Verbreiterung der Resonanzlinien. Andererseits haben wir aber vorhin gesehen, daß ein scharfes Resonanzniveau des Urankerns bei 25 eV existiert. Bohr[14] hat darauf hingewiesen, daß dieser Widerspruch vielleicht so zu verstehen ist, daß die Spaltungsprozesse, die von langsamen Neutronen hervorgerufen werden, das Isotop $^{235}_{92}U$ zum Ausgangskern haben, während am $^{238}_{92}U$ nur der Einfangprozeß stattfindet. Die umgekehrte Zuordnung zu den beiden Isotopen ist nicht möglich infolge der großen Seltenheit von ^{235}U, das nur zu $^1/_{139}$ im natürlichen Uran enthalten ist. Die Theorie von Breit und Wigner fordert nämlich, daß der Einfangquerschnitt für keine Energie den Wert λ^2/π übersteigt, wenn λ die De Broglie-Wellenlänge der Neutronen ist. An der Resonanzstelle ist nun $\lambda^2/\pi = 1{,}0 \cdot 10^{-19}$ cm², der Einfangquerschnitt aber wäre, wenn ^{235}U das Ausgangsisotop ist, $139 \cdot \sigma_r = 3{,}9 \cdot 10^{-19}$ cm², also rund 4 mal so groß wie der größte überhaupt theoretisch zulässige Wert.

c) Der Streuprozeß. Der Streuquerschnitt schneller Neutronen an Uran ist bisher zwar nicht direkt gemessen worden, kann aber zu rund $6 \cdot 10^{-24}$ cm² angenommen werden. Zunächst weiß man nämlich allgemein, daß bei schnellen Neutronen der Streuquerschnitt den Einfangquerschnitt bei weitem übertrifft; zweitens weiß man aus den Messungen des Gesamtquerschnitts durch Dunning und seine Mitarbeiter[15] an zahlreichen Elementen, daß der Querschnitt als Funktion des Atomgewichts von $1{,}6 \cdot 10^{-24}$ cm² bei Wasserstoff bis zu $5{,}8 \cdot 10^{-24}$ cm² bei Blei ohne Unregelmäßigkeiten ansteigt. Der angegebene Wert kann demnach als ziemlich sicher angesehen werden, wenn auch natürlich eine experimentelle Kontrolle erwünscht wäre.

Völlig unbekannt ist gegenwärtig, ob die Streuung nur elastisch erfolgt, oder ob bei einem erheblichen Bruchteil der Streuvorgänge das Neutron den Kern anregt unter Zurücklassung eines wesentlichen Teiles seiner Energie. Der Nachweis solcher unelastischer Streuvorgänge ist nicht einfach und mit Sicherheit bisher nur in dem einen Falle des $^{115}_{49}In$ gelungen[16], wo der entstehende angeregte Kern metastabil ist und mit einer charakteristischen Halbwertszeit von 4,1 Stunden durch β-Zerfall in $^{115}_{50}Sn$ übergeht. Eine genaue Messung des Anregungsquerschnitts ist auch in diesem Falle leider bisher nicht durchgeführt; die Angaben über „starke Aktivität" lassen aber darauf schließen, daß der Querschnitt die Größenordnung von 10^{-24} cm² wohl erreicht.

Über den Streuquerschnitt langsamer Neutronen an Uran gibt es zwar direkte Messungen, doch scheinen sie unverträglich mit anderen Ergebnissen. Vor kurzem wurden an verschiedenen Stellen genaue Messungen des Gesamtquerschnitts von Uran gegenüber thermischen Neutronen angestellt[17]. Dabei ergab sich an metallischem Uran ein Gesamtquerschnitt von $(23{,}2 \pm 0{,}5) \cdot 10^{-24}$ cm², bei Uranoxyd äußert sich der geringe Einfluß der chemischen Bindung in einer Herabsetzung des Querschnitts auf $(20 \pm 2) \cdot 10^{-24}$ cm². Es wurde nun auch der Versuch gemacht, diese Zahl in einen Streu- und einen Absorptionsanteil zu zerlegen, indem der Detektor (ein Silberblech) einmal weit entfernt von der den Neutronenstrahl schwächenden Uranschicht aufgestellt wurde, wo er von den seitwärts herausgestreuten Neutronen nicht erreicht wurde und das andere Mal dicht hinter die Schicht gesetzt wurde, wo ein erheblicher Teil der gestreuten Neutronen noch darauf traf. Der Versuch führte zu einer Zusammensetzung des angegebenen Gesamtquerschnitts ungefähr zu gleichen Teilen aus Streuung und Absorption. Zur Absorption muß man dabei wohl außer dem Einfangprozeß auch die Spaltung rechnen, da die dabei frei werdenden schnellen Neutronen von dem benutzten Detektor nicht mitgezählt werden.

Dies Ergebnis ist nun sehr merkwürdig, wenn man bedenkt, daß die französischen Forscher für thermische Neutronen einen Einfangquerschnitt von nur $1{,}3 \cdot 10^{-24}$ cm² fanden. Zählt man hierzu die von Fermi angegebenen $2 \cdot 10^{-24}$ cm² für die Spaltung, so erhält man für die gesamte Absorption erst etwa $^1/_7$ des angegebenen Gesamtquerschnitts und nicht die Hälfte. Es ist daher nicht unmöglich, daß bei der Messung noch Resonanzneutronen mitgewirkt haben, durch die das Resultat beträchtlich verfälscht wird. Immerhin können wir aus dem Versuch wohl entnehmen, daß Streuquerschnitt und Einfangquerschnitt bei langsamen Neutronen vergleichbar sind.

3. Das Auftreten von Reaktionsketten. Wir wollen die Frage, ob eine Reaktionskette zustandekommen kann, zunächst ganz ohne Berücksichtigung des Diffusionsproblems angreifen. Es sei n die Anzahl der Neutronen, die in einer Substanz von großem Volumen insgesamt enthalten ist. Wir nehmen zunächst an, diese Neutronen seien gleichmäßig dicht über die ganze Substanz verteilt. Ferner sollen verschiedene Arten von Atomen, unterschieden durch den Index i, anwesend sein, an denen Reaktionen stattfinden können, unterschieden durch den Index k, die jeweils ein Neutron zum Verschwinden bringen, also Einfang oder Umwandlung. Bezeichnen wir die Anzahl von Atomen der Art i im Kubikzentimeter mit ϱ_i, die Wirkungsquerschnitte mit σ_{ik}, und ist v die mittlere Geschwindigkeit der Neutronen, so nimmt die Gesamtneutronenzahl in der Zeiteinheit ab um

$$\frac{dn}{dt} = -n\,v \sum_{ik} \varrho_i\,\sigma_{ik}\,.$$

Eine Ausnahme von dieser Regel machen allein die Spaltungsprozesse am Uran, solange wir Thorium ausschließen, das noch nicht so gut untersucht ist, und Neutronenenergien unterhalb 8 MeV fordern, so daß noch keine $(n, 2n)$-Prozesse auftreten können. Ist der Spaltungsquerschnitt σ_{Sp} und die Zahl der bei jeder Spaltung abgedampften Neutronen ν, so haben wir unsere Gleichung zu erweitern zu

$$\frac{1}{n}\,\frac{dn}{dt} = v\Big\{-\sum_{ik} \varrho_i\,\sigma_{ik} + \varrho_{\text{U}}\,\sigma_{\text{Sp}}\,(\nu - 1)\Big\}. \qquad (4a)$$

Die Neutronenzahl nimmt also so lange zu, wie in der Klammer ein positiver Ausdruck steht. Streuprozesse sind nicht mitzuzählen, weil sie die Zahl der Neutronen nicht verändern.

Als Beispiel betrachten wir zunächst die Verhältnisse an reinem Uranmetall. Für schnelle Neutronen besteht kein merkbarer Einfangquerschnitt; wir haben außer $\sigma_{\text{Sp}} = 0{,}1 \cdot 10^{-24}$ cm² nur noch Streuprozesse mit rund $6 \cdot 10^{-24}$ cm². Metallisches Uran (Dichte 8,6) enthält rund $2{,}2 \cdot 10^{22}$ Atome je Kubikzentimeter; es wird dann bei einer Neutronengeschwindigkeit von $2 \cdot 10^9$ cm/sec, entsprechend einer mittleren Energie der frei gesetzten Neutronen von 2 MeV:

$$\frac{1}{n}\,\frac{dn}{dt} = 0{,}44\,(\nu - 1) \cdot 10^7\ \text{sec}^{-1}. \qquad (4b)$$

Die Integration dieser Differentialgleichung ergibt

$$n(t) = n_0\,e^{0{,}44(\nu-1)\cdot 10^7 t}.$$

Läßt man die Reaktionskette mit $n_0 = 1$ Neutron zur Zeit $t = 0$ anlaufen und nimmt man den wahrscheinlichsten Wert $\nu = 2$, so findet man, da je Spaltung $3 \cdot 10^{-12}$ mkg frei werden, folgende Energiebeträge: Nach 10^{-7} sec: $4{,}7 \cdot 10^{-12}$ mkg, nach 10^{-6} sec: $2{,}4 \cdot 10^{-11}$ mkg, nach 10^{-5} sec: $3 \cdot 10^{+7}$ mkg und nach 10^{-4} sec: $3 \cdot 10^{+78}$ mkg. Die letzte Zahl hat natürlich keinen Sinn mehr; sie bedeutet nur, daß in weniger als 10^{-4} sec das gesamte Uran umgesetzt wird. Die Energiebefreiung geschieht also in einer so kurzen Zeit, daß wir es mit einer außerordentlich heftigen Explosion zu tun haben[*].

Es ist gut möglich, daß diese Abschätzung noch in folgendem Sinne zu korrigieren ist: Der Streuquerschnitt für schnelle Neutronen ist rund 60 mal so groß wie der Spaltungsquerschnitt, d. h. ein Neutron wird 60 mal gestreut, ehe es ihm gelingt, einen Urankern zu spalten. Ist nun ein erheblicher Teil dieser Streuung unelastisch, was wir nicht wissen, so wird eine beträchtliche Verlangsamung eintreten. Obwohl bei jeder Spaltung schnelle Neutronen erzeugt werden, dürfen wir dann so rechnen, als ob wir es mit langsamen Neutronen zu tun hätten.

Fig. 1. Einfang- und Spaltungsquerschnitt von Uran für langsame Neutronen. Die Energie E ist in logarithmischer Skala gezeichnet.

Den Verlauf von Spaltungs- und Einfangquerschnitt für langsame Neutronen zeigt Fig. 1. Dann tritt an Stelle von Gl. (4), wenn wir wieder $\nu = 2$ setzen,

$$\frac{1}{n}\,\frac{dn}{dt} = v\,\varrho_{\text{U}}\,(\sigma_{\text{Sp}} - \sigma_{\text{Einf}})\,.$$

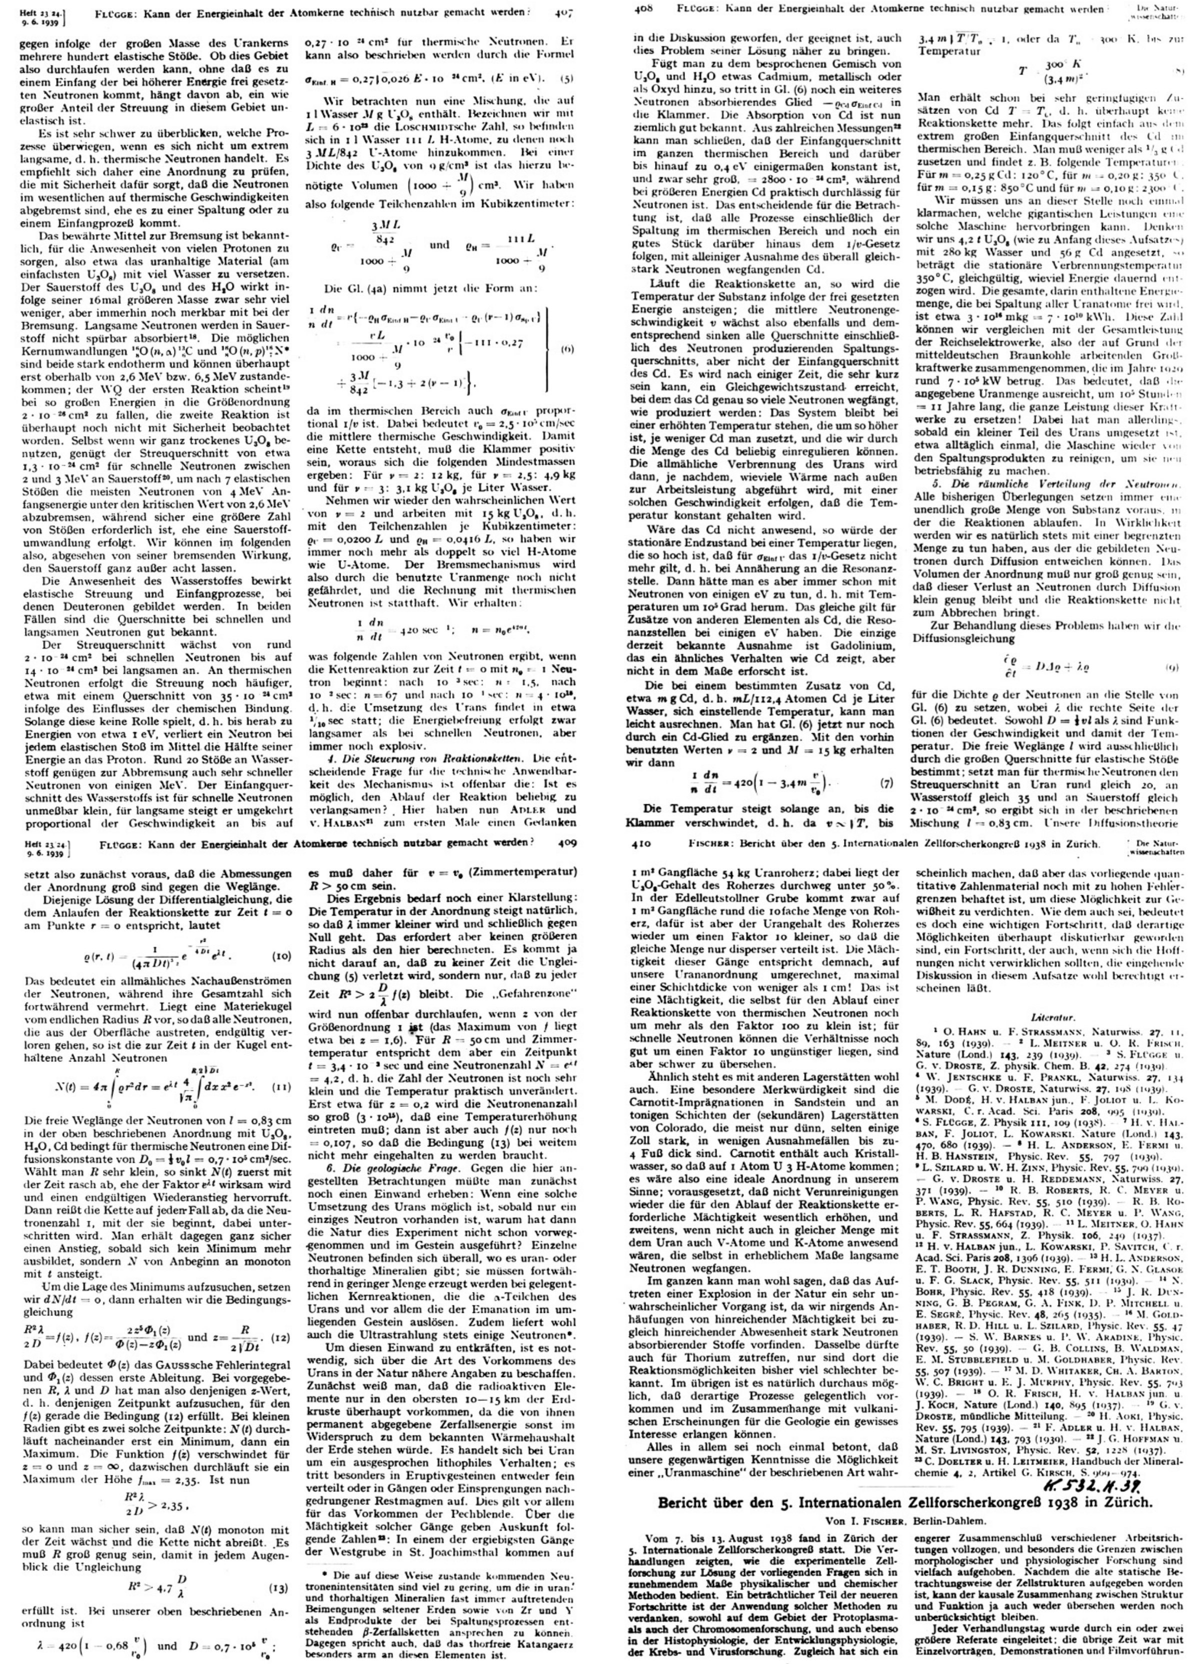
Die Neutronenproduktion wird also überall dort den Einfang überwiegen, wo der Spaltungsquerschnitt größer ist als der Einfangquerschnitt, d. h. überall außer in der Zone von etwa 5 eV bis 40 eV. Zur Durchlaufung dieser Zone sind vielleicht 4 oder 5 unelastische Streuungen notwendig, da-

---

[*] Infolge der Verarmung an Uran läuft die Reaktion allmählich langsamer. Auch dürfte sie nach Umsetzung eines kleinen, aber durchaus wägbaren Bruchteils abbrechen infolge konkurrierender Prozesse an den gebildeten Spaltungsprodukten.

Figure D.50: Siegfried Flügge. Kann der Energieinhalt der Atomkerne technisch nutzbar gemacht werden? *Die Naturwissenschaften* 27:402–410. 9 June 1939. [https://digital.deutsches-museum.de/item/FA-002-746]

Die Naturwissenschaften 27:402-410 (June 1939)



gegen infolge der großen Masse des Urankerns mehrere hundert elastische Stöße. Ob dies Gebiet also durchlaufen werden kann, ohne daß es zu einem Einfang der bei höherer Energie frei gesetzten Neutronen kommt, hängt davon ab, ein wie großer Anteil der Streuung in diesem Gebiet unelastisch ist.

Es ist sehr schwer zu überblicken, welche Prozesse überwiegen, wenn es sich nicht um extrem langsame, d. h. thermische Neutronen handelt. Es empfiehlt sich daher eine Anordnung zu prüfen, die mit Sicherheit dafür sorgt, daß die Neutronen im wesentlichen auf thermische Geschwindigkeiten abgebremst sind, ehe es zu einer Spaltung oder zu einem Einfangprozeß kommt.

Das bewährte Mittel zur Bremsung ist bekanntlich, für die Anwesenheit von vielen Protonen zu sorgen, also etwa das uranhaltige Material (am einfachsten U_3O_8) mit viel Wasser zu versetzen. Der Sauerstoff des U_3O_8 und des H_2O wirkt infolge seiner 16mal größeren Masse zwar sehr viel weniger, aber immerhin noch merkbar mit bei der Bremsung. Langsame Neutronen werden in Sauerstoff nicht spürbar absorbiert[18]. Die möglichen Kernumwandlungen ${}^{16}_{8}O(n,\alpha){}^{13}_{6}C$ und ${}^{16}_{8}O(n,p){}^{16}_{7}N^*$ sind beide stark endotherm und können überhaupt erst oberhalb von 2,6 MeV bzw. 6,5 MeV zustandekommen; der WQ der ersten Reaktion scheint[19] bei so großen Energien in die Größenordnung $2\cdot 10^{-26}\,\text{cm}^2$ zu fallen, die zweite Reaktion ist überhaupt noch nicht mit Sicherheit beobachtet worden. Selbst wenn wir ganz trockenes U_3O_8 benutzen, genügt der Streuquerschnitt von etwa $1{,}3\cdot 10^{-24}\,\text{cm}^2$ für schnelle Neutronen zwischen 2 und 3 MeV an Sauerstoff[20], um nach 7 elastischen Stößen die meisten Neutronen von 4 MeV Anfangsenergie unter den kritischen Wert von 2,6 MeV abzubremsen, während sicher eine größere Zahl von Stößen erforderlich ist, ehe eine Sauerstoffumwandlung erfolgt. Wir können im folgenden also, abgesehen von seiner bremsenden Wirkung, den Sauerstoff ganz außer acht lassen.

Die Anwesenheit des Wasserstoffes bewirkt elastische Streuung und Einfangprozesse, bei denen Deuteronen gebildet werden. In beiden Fällen sind die Querschnitte bei schnellen und langsamen Neutronen gut bekannt.

Der Streuquerschnitt wächst von rund $2\cdot 10^{-24}\,\text{cm}^2$ bei schnellen Neutronen bis auf $14\cdot 10^{-24}\,\text{cm}^2$ bei langsamen an. An thermischen Neutronen erfolgt die Streuung noch häufiger, etwa mit einem Querschnitt von $35\cdot 10^{-24}\,\text{cm}^2$ infolge des Einflusses der chemischen Bindung. Solange diese keine Rolle spielt, d. h. bis herab zu Energien von etwa 1 eV, verliert ein Neutron bei jedem elastischen Stoß im Mittel die Hälfte seiner Energie an das Proton. Rund 20 Stöße an Wasserstoff genügen zur Abbremsung auch sehr schneller Neutronen von einigen MeV. Der Einfangquerschnitt des Wasserstoffs ist für schnelle Neutronen unmeßbar klein, für langsame steigt er umgekehrt proportional der Geschwindigkeit an bis auf $0{,}27\cdot 10^{-24}\,\text{cm}^2$ für thermische Neutronen. Er kann also beschrieben werden durch die Formel

$$\sigma_{\text{Einf. H}} = 0{,}27\sqrt{0{,}026\,E}\cdot 10^{-24}\,\text{cm}^2, \quad (E \text{ in eV}). \qquad (5)$$

Wir betrachten nun eine Mischung, die auf 1 l Wasser M g U_3O_8 enthält. Bezeichnen wir mit $L = 6\cdot 10^{23}$ die LOSCHMIDTsche Zahl, so befinden sich in 1 l Wasser 111 L H-Atome, zu denen noch $3\,ML/842$ U-Atome hinzukommen. Bei einer Dichte des U_3O_8 von 9 g/cm³ ist das hierzu benötigte Volumen $\left(1000+\frac{M}{9}\right)$ cm³. Wir haben also folgende Teilchenzahlen im Kubikzentimeter:

$$\varrho_U = \frac{\frac{3\,ML}{842}}{1000+\frac{M}{9}} \quad \text{und} \quad \varrho_H = \frac{111\,L}{1000+\frac{M}{9}}.$$

Die Gl. (4a) nimmt jetzt die Form an:

$$\left.\begin{aligned}\frac{1}{n}\frac{dn}{dt} &= v\{-\varrho_H\sigma_{\text{Einf H}} - \varrho_U\sigma_{\text{Einf U}} + \varrho_U(\nu-1)\sigma_{\text{Sp U}}\}\\ &= \frac{vL}{1000+\frac{M}{9}}\cdot 10^{-24}\,\frac{v_0}{v}\Big\{-111\cdot 0{,}27\\ &\quad + \frac{3M}{842}[-1{,}3+2(\nu-1)]\Big\},\end{aligned}\right\} \qquad (6)$$

da im thermischen Bereich auch $\sigma_{\text{Einf U}}$ proportional $1/v$ ist. Dabei bedeutet $v_0 = 2{,}5\cdot 10^5$ cm/sec die mittlere thermische Geschwindigkeit. Damit eine Kette entsteht, muß die Klammer positiv sein, woraus sich die folgenden Mindestmassen ergeben: Für $\nu = 2$: 12 kg, für $\nu = 2{,}5$: 4,9 kg und für $\nu = 3$: 3,1 kg U_3O_8 je Liter Wasser.

Nehmen wir wieder den wahrscheinlichen Wert von $\nu = 2$ und arbeiten mit 15 kg U_3O_8, d. h. mit den Teilchenzahlen je Kubikzentimeter: $\varrho_U = 0{,}0200\,L$ und $\varrho_H = 0{,}0416\,L$, so haben wir immer noch mehr als doppelt so viel H-Atome wie U-Atome. Der Bremsmechanismus wird also durch die benutzte Uranmenge noch nicht gefährdet, und die Rechnung mit thermischen Neutronen ist statthaft. Wir erhalten:

$$\frac{1}{n}\frac{dn}{dt} = 420\,\text{sec}^{-1}; \quad n = n_0 e^{420t},$$

was folgende Zahlen von Neutronen ergibt, wenn die Kettenreaktion zur Zeit $t = 0$ mit $n_0 = 1$ Neutron beginnt: nach 10^{-3} sec: $n = 1{,}5$, nach 10^{-2} sec: $n = 67$ und nach 10^{-1} sec: $n = 4\cdot 10^{18}$, d. h. die Umsetzung des Urans findet in etwa $^1/_{10}$ sec statt; die Energiebefreiung erfolgt zwar langsamer als bei schnellen Neutronen, aber immer noch explosiv.

4. Die Steuerung von Reaktionsketten. Die entscheidende Frage für die technische Anwendbarkeit des Mechanismus ist offenbar die: Ist es möglich, den Ablauf der Reaktion beliebig zu verlangsamen? Hier haben nun ADLER und v. HALBAN[21] zum ersten Male einen Gedanken in die Diskussion geworfen, der geeignet ist, auch dies Problem seiner Lösung näher zu bringen.

Fügt man zu dem besprochenen Gemisch von U_3O_8 und H_2O etwas Cadmium, metallisch oder als Oxyd hinzu, so tritt in Gl. (6) noch ein weiteres Neutronen absorbierendes Glied $-\varrho_{\text{Cd}}\sigma_{\text{Einf Cd}}$ in die Klammer. Die Absorption von Cd ist nun ziemlich gut bekannt. Aus zahlreichen Messungen[22] kann man schließen, daß der Einfangquerschnitt im ganzen thermischen Bereich und darüber bis hinauf zu 0,4 eV einigermaßen konstant ist, und zwar sehr groß, $= 2800\cdot 10^{-24}\,\text{cm}^2$, während bei größeren Energien Cd praktisch durchlässig für Neutronen ist. Das entscheidende für die Betrachtung ist, daß alle Prozesse einschließlich der Spaltung im thermischen Bereich und noch ein gutes Stück darüber hinaus dem $1/v$-Gesetz folgen, mit alleiniger Ausnahme des überall gleichstark Neutronen wegfangenden Cd.

Läuft die Reaktionskette an, so wird die Temperatur der Substanz infolge der frei gesetzten Energie ansteigen; die mittlere Neutronengeschwindigkeit v wächst also ebenfalls und dementsprechend sinken alle Querschnitte einschließlich des Neutronen produzierenden Spaltungsquerschnitts, aber nicht der Einfangquerschnitt des Cd. Es wird nach einiger Zeit, die sehr kurz sein kann, ein Gleichgewichtszustand erreicht, bei dem das Cd genau so viele Neutronen wegfängt, wie produziert werden: Das System bleibt bei einer erhöhten Temperatur stehen, die um so höher ist, je weniger Cd man zusetzt, und die wir durch die Menge des Cd beliebig einregulieren können. Die allmähliche Verbrennung des Urans wird dann, je nachdem, wieviele Wärme nach außen zur Arbeitsleistung abgeführt wird, mit einer solchen Geschwindigkeit erfolgen, daß die Temperatur konstant gehalten wird.

Wäre das Cd nicht anwesend, so würde der stationäre Endzustand bei einer Temperatur liegen, die so hoch ist, daß für $\sigma_{\text{Einf U}}$ das $1/v$-Gesetz nicht mehr gilt, d. h. bei Annäherung an die Resonanzstelle. Dann hätte man es aber immer schon mit Neutronen von einigen eV zu tun, d. h. mit Temperaturen um 10^5 Grad herum. Das gleiche gilt für Zusätze von anderen Elementen als Cd, die Resonanzstellen bei einigen eV haben. Die einzige derzeit bekannte Ausnahme ist Gadolinium, das ein ähnliches Verhalten wie Cd zeigt, aber nicht in dem Maße erforscht ist.

Die bei einem bestimmten Zusatz von Cd, etwa m g Cd, d. h. $mL/112{,}4$ Atomen Cd je Liter Wasser, sich einstellende Temperatur, kann man leicht ausrechnen. Man hat Gl. (6) jetzt nur noch durch ein Cd-Glied zu ergänzen. Mit den vorhin benutzten Werten $\nu = 2$ und $M = 15$ kg erhalten wir dann

$$\frac{1}{n}\frac{dn}{dt} = 420\left(1 - 3{,}4\,m\,\frac{v}{v_0}\right). \qquad (7)$$

Die Temperatur steigt solange an, bis die Klammer verschwindet, d. h. da $v \sim \sqrt{T}$, bis $3{,}4\,m\sqrt{T/T_0} = 1$, oder da $T_0 = 300°$ K, bis zur Temperatur

$$T = \frac{300°\,K}{(3{,}4\,m)^2}. \qquad (8)$$

Man erhält schon bei sehr geringfügigen Zusätzen von Cd $T = T_0$, d. h. überhaupt keine Reaktionskette mehr. Das folgt einfach aus dem extrem großen Einfangquerschnitt des Cd im thermischen Bereich. Man muß weniger als $^1/_3$ g Cd zusetzen und findet z. B. folgende Temperaturen: Für $m = 0{,}25$ g Cd: 120° C, für $m = 0{,}20$ g: 350° C, für $m = 0{,}15$ g: 850° C und für $m = 0{,}10$ g: 2300° C.

Wir müssen uns an dieser Stelle noch einmal klarmachen, welche gigantischen Leistungen eine solche Maschine hervorbringen kann. Denken wir uns 4,2 t U_3O_8 (wie zu Anfang dieses Aufsatzes) mit 280 kg Wasser und 56 g Cd angesetzt, so beträgt die stationäre Verbrennungstemperatur 350° C, gleichgültig, wieviel Energie dauernd entzogen wird. Die gesamte, darin enthaltene Energiemenge, die bei Spaltung aller Uranatome frei wird, ist etwa $3\cdot 10^{16}$ mkg $= 7\cdot 10^{10}$ kWh. Diese Zahl können wir vergleichen mit der Gesamtleistung der Reichselektrowerke, also der auf Grund der mitteldeutschen Braunkohle arbeitenden Großkraftwerke zusammengenommen, die im Jahre 1020 rund $7\cdot 10^5$ kW betrug. Das bedeutet, daß die angegebene Uranmenge ausreicht, um 10^5 Stunden $= 11$ Jahre lang, die ganze Leistung dieser Kraftwerke zu ersetzen! Dabei hat man allerdings, sobald ein kleiner Teil des Urans umgesetzt ist, etwa alltäglich einmal, die Maschine wieder von den Spaltungsprodukten zu reinigen, um sie neu betriebsfähig zu machen.

5. Die räumliche Verteilung der Neutronen. Alle bisherigen Überlegungen setzen immer eine unendlich große Menge von Substanz voraus, in der die Reaktionen ablaufen. In Wirklichkeit werden wir es natürlich stets mit einer begrenzten Menge zu tun haben, aus der die gebildeten Neutronen durch Diffusion entweichen können. Das Volumen der Anordnung muß nur groß genug sein, daß dieser Verlust an Neutronen durch Diffusion klein genug bleibt und die Reaktionskette nicht zum Abbrechen bringt.

Zur Behandlung dieses Problems haben wir die Diffusionsgleichung

$$\frac{\partial\varrho}{\partial t} = D\Delta\varrho + \lambda\varrho \qquad (9)$$

für die Dichte ϱ der Neutronen an die Stelle von Gl. (6) zu setzen, wobei λ die rechte Seite der Gl. (6) bedeutet. Sowohl $D = \frac{1}{3}vl$ als λ sind Funktionen der Geschwindigkeit und damit der Temperatur. Die freie Weglänge l wird ausschließlich durch die großen Querschnitte für elastische Stöße bestimmt; setzt man für thermische Neutronen den Streuquerschnitt an Uran rund gleich 20, an Wasserstoff gleich 35 und an Sauerstoff gleich $2\cdot 10^{-24}\,\text{cm}^2$, so ergibt sich in der beschriebenen Mischung $l = 0{,}83$ cm. Unsere Diffusionstheorie setzt also zunächst voraus, daß die Abmessungen der Anordnung groß sind gegen die Weglänge.

Diejenige Lösung der Differentialgleichung, die dem Anlaufen der Reaktionskette zur Zeit $t = 0$ am Punkte $r = 0$ entspricht, lautet

$$\varrho(r,t) = \frac{1}{(4\pi Dt)^{3/2}}\,e^{-\frac{r^2}{4Dt}}\,e^{\lambda t}. \qquad (10)$$

Das bedeutet ein allmähliches Nachaußenströmen der Neutronen, während ihre Gesamtzahl sich fortwährend vermehrt. Liegt eine Materiekugel vom endlichen Radius R vor, so daß alle Neutronen, die aus der Oberfläche austreten, endgültig verloren gehen, so ist die zur Zeit t in der Kugel enthaltene Anzahl Neutronen

$$N(t) = 4\pi\int_0^R \varrho r^2\,dr = e^{\lambda t}\,\frac{4}{\sqrt{\pi}}\int_0^{R/2\sqrt{Dt}} dx\,x^2 e^{-x^2}. \qquad (11)$$

Die freie Weglänge der Neutronen von $l = 0{,}83$ cm in der oben beschriebenen Anordnung mit U_3O_8, H_2O, Cd bedingt für thermische Neutronen eine Diffusionskonstante von $D_0 = \frac{1}{3}v_0 l = 0{,}7\cdot 10^5\,\text{cm}^2/\text{sec}$. Wählt man R sehr klein, so sinkt $N(t)$ zuerst mit der Zeit rasch ab, ehe der Faktor $e^{\lambda t}$ wirksam wird und einen endgültigen Wiederanstieg hervorruft. Dann reißt die Kette auf jeden Fall ab, da die Neutronenzahl 1, mit der sie beginnt, dabei unterschritten wird. Man erhält dagegen ganz sicher einen Anstieg, sobald sich kein Minimum mehr ausbildet, sondern N von Anbeginn an monoton mit t ansteigt.

Um die Lage des Minimums aufzusuchen, setzen wir $dN/dt = 0$, dann erhalten wir die Bedingungsgleichung

$$\frac{R^2\lambda}{2D} = f(z), \quad f(z) = \frac{2z^5\Phi_1(z)}{\Phi(z) - z\Phi_1(z)} \quad \text{und} \quad z = \frac{R}{2\sqrt{Dt}}. \qquad (12)$$

Dabei bedeutet $\Phi(z)$ das GAUSSsche Fehlerintegral und $\Phi_1(z)$ dessen erste Ableitung. Bei vorgegebenen R, λ und D hat man also denjenigen z-Wert, d. h. denjenigen Zeitpunkt aufzusuchen, für den $f(z)$ gerade die Bedingung (12) erfüllt. Bei kleinen Radien gibt es zwei solche Zeitpunkte: $N(t)$ durchläuft nacheinander erst ein Minimum, dann ein Maximum. Die Funktion $f(z)$ verschwindet für $z = 0$ und $z = \infty$, dazwischen durchläuft sie ein Maximum der Höhe $f_{\max} = 2{,}35$. Ist nun

$$\frac{R^2\lambda}{2D} > 2{,}35,$$

so kann man sicher sein, daß $N(t)$ monoton mit der Zeit wächst und die Kette nicht abreißt. Es muß R groß genug sein, damit in jedem Augenblick die Ungleichung

$$R^2 > 4{,}7\,\frac{D}{\lambda} \qquad (13)$$

erfüllt ist. Bei unserer oben beschriebenen Anordnung ist

$$\lambda = 420\left(1 - 0{,}68\,\frac{v}{v_0}\right) \quad \text{und} \quad D = 0{,}7\cdot 10^5\,\frac{v}{v_0};$$

es muß daher für $v = v_0$ (Zimmertemperatur) $R > 50$ cm sein.

Dies Ergebnis bedarf noch einer Klarstellung: Die Temperatur in der Anordnung steigt natürlich, so daß λ immer kleiner wird und schließlich gegen Null geht. Das erfordert aber keinen größeren Radius als den hier berechneten. Es kommt ja nicht darauf an, daß zu keiner Zeit die Ungleichung (5) verletzt wird, sondern nur, daß zu jeder Zeit $R^2 > 2\,\frac{D}{\lambda}\,f(z)$ bleibt. Die „Gefahrenzone" wird nun offenbar durchlaufen, wenn z von der Größenordnung 1 ist (das Maximum von f liegt etwa bei $z = 1{,}6$). Für $R = 50$ cm und Zimmertemperatur entspricht dem aber ein Zeitpunkt $t = 3{,}4\cdot 10^{-3}$ sec und eine Neutronenzahl $N = e^{\lambda t} = 4{,}2$, d. h. die Zahl der Neutronen ist noch sehr klein und die Temperatur praktisch unverändert. Erst etwa für $z = 0{,}2$ wird die Neutronenanzahl so groß ($3\cdot 10^{15}$), daß eine Temperaturerhöhung eintreten muß; dann ist aber auch $f(z)$ nur noch $= 0{,}107$, so daß die Bedingung (13) bei weitem nicht mehr eingehalten zu werden braucht.

6. Die geologische Frage. Gegen die hier angestellten Betrachtungen müßte man zunächst noch einen Einwand erheben: Wenn eine solche Umsetzung des Urans möglich ist, sobald nur ein einziges Neutron vorhanden ist, warum hat dann die Natur dies Experiment nicht schon vorweggenommen und im Gestein ausgeführt? Einzelne Neutronen befinden sich überall, wo es uran- oder thorhaltige Mineralien gibt; sie müssen fortwährend in geringer Menge erzeugt werden bei gelegentlichen Kernreaktionen, die die α-Teilchen des Urans und vor allem die der Emanation im umliegenden Gestein auslösen. Zudem liefert wohl auch die Ultrastrahlung stets einige Neutronen*.

Um diesen Einwand zu entkräften, ist es notwendig, sich über die Art des Vorkommens des Urans in der Natur nähere Angaben zu beschaffen. Zunächst weiß man, daß die radioaktiven Elemente nur in den obersten 10—15 km der Erdkruste überhaupt vorkommen, da die von ihnen permanent abgegebene Zerfallsenergie sonst im Widerspruch zu dem bekannten Wärmehaushalt der Erde stehen würde. Es handelt sich bei Uran um ein ausgesprochen lithophiles Verhalten; es tritt besonders in Eruptivgesteinen entweder fein verteilt oder in Gängen oder Einsprengungen nachgedrungener Restmagmen auf. Dies gilt vor allem für das Vorkommen der Pechblende. Über die Mächtigkeit solcher Gänge geben Auskunft folgende Zahlen[23]: In einem der ergiebigsten Gänge der Westgrube in St. Joachimsthal kommen auf 1 m² Gangfläche 54 kg Uranroherz; dabei liegt der U_3O_8-Gehalt des Roherzes durchweg unter 50%. In der Edelleutstollner Grube kommt zwar auf 1 m² Gangfläche rund die 10fache Menge von Roherz, dafür ist aber der Urangehalt des Roherzes wieder um einen Faktor 10 kleiner, so daß die gleiche Menge nur disperser verteilt ist. Die Mächtigkeit dieser Gänge entspricht demnach, auf unsere Urananordnung umgerechnet, maximal einer Schichtdicke von weniger als 1 cm! Das ist eine Mächtigkeit, die selbst für den Ablauf einer Reaktionskette von thermischen Neutronen noch um mehr als den Faktor 100 zu klein ist; für schnelle Neutronen können die Verhältnisse noch gut um einen Faktor 10 ungünstiger liegen, sind aber schwer zu übersehen.

---

* Die auf diese Weise zustande kommenden Neutronenintensitäten sind viel zu gering, um die in uran- und thorhaltigen Mineralien fast immer auftretenden Beimengungen seltener Erden sowie von Zr und Y als Endprodukte der bei Spaltungsprozessen entstehenden β-Zerfallsketten ansprechen zu können. Dagegen spricht auch, daß das thorfreie Katangaerz besonders arm an diesen Elementen ist.

Ähnlich steht es mit anderen Lagerstätten wohl auch. Eine besondere Merkwürdigkeit sind die Carnotit-Imprägnationen in Sandstein und an tonigen Schichten der (sekundären) Lagerstätten von Colorado, die meist nur dünn, selten einige Zoll stark, in wenigen Ausnahmefällen bis zu 4 Fuß dick sind. Carnotit enthält auch Kristallwasser, so daß auf 1 Atom U 3 H-Atome kommen; es wäre also eine ideale Anordnung in unserem Sinne; vorausgesetzt, daß nicht Verunreinigungen wieder die für den Ablauf der Reaktionskette erforderliche Mächtigkeit wesentlich erhöhen, und zweitens, wenn nicht auch in gleicher Menge mit dem Uran auch V-Atome und K-Atome anwesend wären, die selbst in erheblichem Maße langsame Neutronen wegfangen.

Im ganzen kann man wohl sagen, daß das Auftreten einer Explosion in der Natur ein sehr unwahrscheinlicher Vorgang ist, da wir nirgends Anhäufungen von hinreichender Mächtigkeit bei zugleich hinreichender Abwesenheit stark Neutronen absorbierender Stoffe vorfinden. Dasselbe dürfte auch für Thorium zutreffen, nur sind dort die Reaktionsmöglichkeiten bisher viel schlechter bekannt. Im übrigen ist es natürlich durchaus möglich, daß derartige Prozesse gelegentlich vorkommen und im Zusammenhange mit vulkanischen Erscheinungen für die Geologie ein gewisses Interesse erlangen können.

Alles in allem sei noch einmal betont, daß unsere gegenwärtigen Kenntnisse die Möglichkeit einer „Uranmaschine" der beschriebenen Art wahrscheinlich machen, daß aber das vorliegende quantitative Zahlenmaterial noch mit zu hohen Fehlergrenzen behaftet ist, um diese Möglichkeit zur Gewißheit zu verdichten. Wie dem auch sei, bedeutet es doch eine wichtigen Fortschritt, daß derartige Möglichkeiten überhaupt diskutierbar geworden sind, ein Fortschritt, der auch, wenn sich die Hoffnungen nicht verwirklichen sollten, die eingehende Diskussion in diesem Aufsatze wohl berechtigt erscheinen läßt.

Bericht über den 5. Internationalen Zellforscherkongreß 1938 in Zürich.

Von I. FISCHER, Berlin-Dahlem.

Vom 7. bis 13. August 1938 fand in Zürich der 5. Internationale Zellforscherkongreß statt. Die Verhandlungen zeigten, wie die experimentelle Zellforschung zur Lösung der vorliegenden Fragen sich in zunehmendem Maße physikalischer und chemischer Methoden bedient. Ein beträchtlicher Teil der neueren Fortschritte ist der Anwendung solcher Methoden zu verdanken, sowohl auf dem Gebiet der Protoplasma- als auch der Chromosomenforschung, und auch ebenso in der Histophysiologie, der Entwicklungsphysiologie, der Krebs- und Virusforschung. Zugleich hat sich ein engerer Zusammenschluß verschiedener Arbeitsrichtungen vollzogen, und besonders die Grenzen zwischen morphologischer und physiologischer Forschung sind vielfach aufgehoben. Nachdem die alte statische Betrachtungsweise der Zellstrukturen aufgegeben worden ist, kann der kausale Zusammenhang zwischen Struktur und Funktion ja auch weder übersehen werden noch unberücksichtigt bleiben.

Jeder Verhandlungstag wurde durch ein oder zwei größere Referate eingeleitet; die übrige Zeit war mit Einzelvorträgen, Demonstrationen und Filmvorführun-

ÖSTERREICHISCHES PATENTAMT

Kl. 21 i$_{4}$, 4/10

PATENTSCHRIFT NR. 219170

Ausgegeben am 10. Jänner 1962

ALPENLÄNDISCHER ZENTRALVEREIN ZUR FÖRDERUNG SCHÖPFERISCHEN SCHAFFENS IN SALZBURG

Vorrichtung zur technischen Energiegewinnung mit Hilfe von Kernspaltungsreaktionen

Angemeldet am 30. Juni 1958 (A 4597/58); als Tag der Anmeldung gilt der
14. Juni 1939 (Tag der Hinterlegung beim Deutschen Reichspatentamt).
Beginn der Patentdauer: 15. Juni 1961.
Längste mögliche Dauer: 14. Juni 1971.
Als Erfinder wird genannt: Dr. Georg Stetter in Zell am See (Salzburg).

Die Erfindung bezieht sich auf eine Vorrichtung zur technischen Energiegewinnung mit Hilfe von Kernspaltungsreaktionen, wobei außer den eigentlichen Spaltsubstanzen (Brennstoff) neutronenstreuende Substanzen (Moderator) und gegebenenfalls neutronenabsorbierende Substanzen (Absorber) verwendet sind.

In derartigen Vorrichtungen (Spaltungsreaktoren) wird die Aufrechterhaltung der energieproduzierenden, mit Hilfe der bei der Kernspaltung entstehenden Spaltneutronen (Sekundärneutronen) als Kettenreaktion ablaufenden Kernspaltungen dadurch bewirkt, daß die schnellen Spaltneutronen in den neutronenstreuenden Substanzen (Moderator) auf langsame Geschwindigkeiten gebremst (moderiert) werden. Dieser Vorgang erhöht die Häufigkeit der Kernspaltungen und damit auch der Neutronenproduktion, da Kernspaltungen in überwiegendem Maße von langsamen Neutronen bewirkt werden. Die Neutronenbilanz wird gehoben, wodurch erhöhte Neutronenverluste, welche den Abbruch der Kettenreaktion zur Folge haben, kompensiert werden können.

Eine derartige Vorrichtung wurde von S. Flügge in der Zeitschrift Naturwissenschaften 27 [1939] im Heft 23/24 vom 9. 6. 1939, S. 402/410 beschrieben, wobei nach dem Vorschlag von S. Flügge die Spaltsubstanzen (Brennstoff) mit den neutronenstreuenden Substanzen (Moderator) homogen gemischt sind (homogener Spaltungsreaktor).

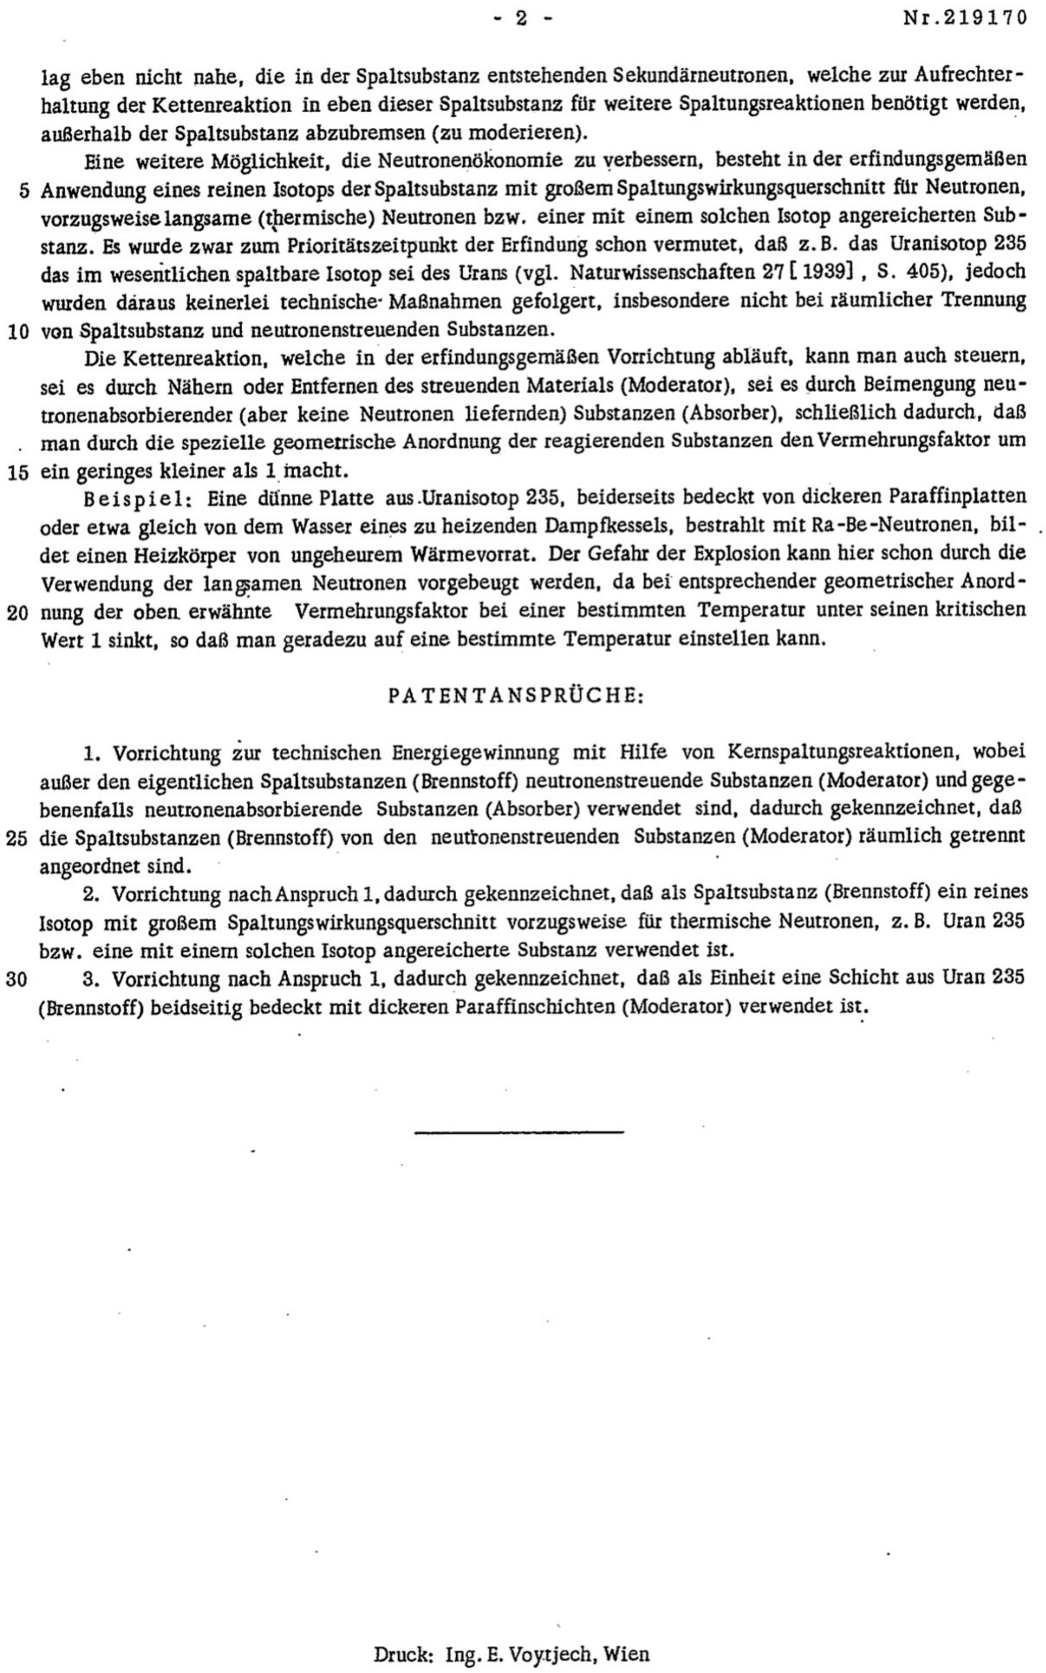
Die Neutronenökonomie ist jedoch infolge starken Neutroneneinfanges durch die Spaltsubstanzen bei einer homogenen Mischung von Spaltsubstanzen und neutronenstreuenden Substanzen nicht gut, so daß eine Kettenreaktion nur unter erschwerenden technischen Bedingungen in Gang gesetzt und aufrechterhalten werden kann.

Dieser Mangel wird durch die Erfindung dadurch behoben, daß die Spaltsubstanzen (Brennstoff) von den Neutronen streuenden Substanzen (Moderator) räumlich getrennt angeordnet sind (heterogener Spaltungsreaktor). Unter "räumlich getrennt" wird hier das Gegenteil einer homogenen Mischung verstanden, nämlich die "makroskopische" Eigenständlichkeit der Bereiche der Spaltsubstanzen (Brennstoffbereiche) und der Bereiche der neutronenstreuenden Substanzen (Moderatorbereiche).

Dadurch, daß auf diese Weise die Spaltneutronen in von der Spaltsubstanz hinreichend entfernten Bereichen auf thermische Geschwindigkeit abgebremst werden, entgehen sie leichter den Einfangprozessen, welche bei bestimmten mittleren Geschwindigkeiten (Resonanzbereichen) der Neutronen in besonderem Maße auftreten. Der Vermehrungsfaktor für die Spaltneutronen erreicht auf diese Weise - bedingt auch durch die geometrische Anordnung der Spaltsubstanzen und neutronenstreuenden Substanzen - den kritischen Wert 1 für stationären Reaktorbetrieb.

Vor dem Prioritätszeitpunkt der Erfindung hatte man lediglich in Experimentieranordnungen die von einem Ra-Be-Präparat ausgesandten Primärneutronen in räumlich von der Spaltsubstanz getrennt angeordneten neutronenstreuenden Substanzen gebremst (vgl. Comptes Rendus 208, [1939], S. 898/900). Es ist jedoch vor dem Prioritätszeitpunkt der Erfindung nicht bekanntgeworden, eine derartige Anordnung auch zur Bremsung von in der Spaltsubstanz entstehenden Sekundärneutronen (Spaltneutronen) vorzusehen. Es

Figure D.52: Georg Stetter. Austrian patent AT219170. Vorrichtung zur technischen Energiegewinnung mit Hilfe von Kernspaltungsreaktionen [Apparatus for Technical Energy Production by Means of Nuclear Fission Reactions]. Filed 14 June 1939.



lag eben nicht nahe, die in der Spaltsubstanz entstehenden Sekundärneutronen, welche zur Aufrechterhaltung der Kettenreaktion in eben dieser Spaltsubstanz für weitere Spaltungsreaktionen benötigt werden, außerhalb der Spaltsubstanz abzubremsen (zu moderieren).

Eine weitere Möglichkeit, die Neutronenökonomie zu verbessern, besteht in der erfindungsgemäßen Anwendung eines reinen Isotops der Spaltsubstanz mit großem Spaltungswirkungsquerschnitt für Neutronen, vorzugsweise langsame (thermische) Neutronen bzw. einer mit einem solchen Isotop angereicherten Substanz. Es wurde zwar zum Prioritätszeitpunkt der Erfindung schon vermutet, daß z.B. das Uranisotop 235 das im wesentlichen spaltbare Isotop sei des Urans (vgl. Naturwissenschaften 27 [1939], S. 405), jedoch wurden daraus keinerlei technische Maßnahmen gefolgert, insbesondere nicht bei räumlicher Trennung von Spaltsubstanz und neutronenstreuenden Substanzen.

Die Kettenreaktion, welche in der erfindungsgemäßen Vorrichtung abläuft, kann man auch steuern, sei es durch Nähern oder Entfernen des streuenden Materials (Moderator), sei es durch Beimengung neutronenabsorbierender (aber keine Neutronen liefernden) Substanzen (Absorber), schließlich dadurch, daß man durch die spezielle geometrische Anordnung der reagierenden Substanzen den Vermehrungsfaktor um ein geringes kleiner als 1 macht.

Beispiel: Eine dünne Platte aus Uranisotop 235, beiderseits bedeckt von dickeren Paraffinplatten oder etwa gleich von dem Wasser eines zu heizenden Dampfkessels, bestrahlt mit Ra-Be-Neutronen, bildet einen Heizkörper von ungeheurem Wärmevorrat. Der Gefahr der Explosion kann hier schon durch die Verwendung der langsamen Neutronen vorgebeugt werden, da bei entsprechender geometrischer Anordnung der oben erwähnte Vermehrungsfaktor bei einer bestimmten Temperatur unter seinen kritischen Wert 1 sinkt, so daß man geradezu auf eine bestimmte Temperatur einstellen kann.

PATENTANSPRÜCHE:

1. Vorrichtung zur technischen Energiegewinnung mit Hilfe von Kernspaltungsreaktionen, wobei außer den eigentlichen Spaltsubstanzen (Brennstoff) neutronenstreuende Substanzen (Moderator) und gegebenenfalls neutronenabsorbierende Substanzen (Absorber) verwendet sind, dadurch gekennzeichnet, daß die Spaltsubstanzen (Brennstoff) von den neutronenstreuenden Substanzen (Moderator) räumlich getrennt angeordnet sind.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß als Spaltsubstanz (Brennstoff) ein reines Isotop mit großem Spaltungswirkungsquerschnitt vorzugsweise für thermische Neutronen, z.B. Uran 235 bzw. eine mit einem solchen Isotop angereicherte Substanz verwendet ist.

3. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß als Einheit eine Schicht aus Uran 235 (Brennstoff) beidseitig bedeckt mit dickeren Paraffinschichten (Moderator) verwendet ist.

Figure D.53: Georg Stetter. Austrian patent AT219170. Vorrichtung zur technischen Energiegewinnung mit Hilfe von Kernspaltungsreaktionen [Apparatus for Technical Energy Production by Means of Nuclear Fission Reactions]. Filed 14 June 1939.

Georg Stetter. Austrian patent AT219170. Vorrichtung zur technischen Energiegewinnung mit Hilfe von Kernspaltungsreaktionen [Apparatus for Technical Energy Production by Means of Nuclear Fission Reactions]. Filed 14 June 1939.

Die Erfindung bezieht sich auf eine Vorrichtung zur technischen Energiegewinnung mit Hilfe von Kernspaltungsreaktionen, wobei ausser den eigentlichen Spaltsubstanzen (Brennstoff) neutronenstreuende Substanzen (Moderator) und gegebenenfalls neutronenabsorbierende Substanzen (Absorber) verwendet sind.

In derartigen Vorrichtungen (Spaltungsreaktoren) wird die Aufrechterhaltung der energieproduzierenden, mit Hilfe der bei der Kernspaltung entstehenden Spaltneutronen (Sekundärneutronen) als Kettenreaktion ablaufenden Kernspaltungen dadurch bewirkt, dass die schnellen Spaltneutronen in den neutronenstreuenden Substanzen (Moderator) auf langsame Geschwindigkeiten gebremst (moderiert) werden. Dieser Vorgang erhöht die Häufigkeit der Kernspaltungen und damit auch der Neutronenproduktion, da Kernspaltungen in überwiegendem Masse von langsamen Neutronen bewirkt werden. Die Neutronenbilanz wird gehoben, wodurch erhöhte Neutronenverluste, welche den Abbruch der Kettenreaktion zur Folge haben, kompensiert werden können.

Eine derartige Vorrichtung wurde von S. Flügge in der Zeitschrift *Naturwissenschaften* 27 [1939] im Heft 23/24 vom 9. 6. 1939, S. 402/410 beschrieben, wobei nach dem Vorschlag von S. Flügge die Spaltsubstanzen (Brennstoff) mit den neutronenstreuenden Substanzen (Moderator) homogen gemischt sind (homogener Spaltungsreaktor).

Die Neutronenökonomie ist jedoch infolge starken Neutroneneinfanges durch die Spaltsubstanzen bei einer homogenen Mischung von Spaltsubstanzen und neutronenstreuenden Substanzen nicht gut, so dass eine Kettenreaktion nur unter erschwerenden technischen Bedingungen in Gang gesetzt und aufrechterhalten werden kann.

The invention relates to a device for the production of technical energy by means of nuclear fission reactions. Apart from the actual fission substances (fuel), neutron scattering substances (moderator) and possibly neutron-absorbing substances (absorbers) are used.

In such devices (fission reactors), the maintenance of the energy-producing nuclear fissions occurring as a chain reaction during secondary fission (secondary fission) is effected by slowing (moderating) the fast fission neutrons in the neutron scattering substances (moderator) to slow speeds. This process increases the frequency of nuclear fission and thus also neutron production, since nuclear fission is predominantly caused by slow neutrons. The neutron balance is lifted, as a result of which increased neutron losses, which result in the termination of the chain reaction, can be compensated for.

Such a device has been described by S. Flügge in the journal *Naturwissenschaften* 27 [1939] in issue 23/24 of 9 June 1939, p. 402/410. According to the proposal by S. Flügge, the fission substances (fuel) are homogeneously mixed with the neutron scattering substances (moderator) (homogeneous fission reactor).

The neutron economy, however, is not good due to strong neutron capture by the fission substances in a homogeneous mixture of fission substances and neutron scattering substances so that a chain reaction can only be initiated and maintained under aggravating technical conditions.

Dieser Mangel wird durch die Erfindung dadurch behoben, dass die Spaltsubstanzen (Brennstoff) von den Neutronen streuenden Substanzen (Moderator) räumlich getrennt angeordnet sind (heterogener Spaltungsreaktor). Unter “räumlich getrennt” wird hier das Gegenteil einer homogenen Mischung verstanden, nämlich die “makroskopische” Eigenständlichkeit der Bereiche der Spaltsubstanzen (Brennstoffbereiche) und der Bereiche der neutronenstreuenden Substanzen (Moderatorbereiche).

Dadurch, dass auf diese Weise die Spaltneutronen in von der Spaltsubstanz hinrei-chend entfernten Bereichen auf thermische Geschwindigkeit abgebremst werden, entgehen sie leichter den Einfangprozessen, welche bei bestimmten mittleren Geschwindigkeiten (Resonanzbereichen) der Neutronen in besonderem Masse auftreten. Der Vermehrungsfaktor für die Spaltneutronen erreicht auf diese Weise—bedingt auch durch die geometrische Anordnung der Spaltsubstanzen und neutronenstreuenden Substanzen—den kritischen Wert 1 für stationären Reaktorbetrieb.

Vor dem Prioritätszeitpunkt der Erfindung hatte man lediglich in Experimentier-anordnungen die von einem Ra-Be-Präparat ausgesandten Primärneutronen in räumlich von der Spaltsubstanz getrennt angeordneten neutronenstreuenden Substanzen gebremst (vgl. *Comptes Rendus* 208, [1939] S. 898/900). Es ist jedoch vor dem Prioritätszeitpunkt der Erfindung nicht bekanntgeworden, eine derartige Anordnung auch zur Bremsung von in der Spaltsubstanz entstehenden Sekundärneutronen (Spaltneutronen) vorzusehen. Es lag eben nicht nahe, die in der Spaltsubstanz entstehenden Sekundärneutronen, welche zur Aufrechterhaltung der Kettenreaktion in eben dieser Spaltsubstanz für weitere Spaltungsreaktionen benötigt werden, ausserhalb der Spaltsubstanz abzubremsen (zu moderieren).

This deficiency is remedied by the invention in that the fissionable substances (fuel) from the neutron-scattering substances (moderator) are spatially separated (heterogeneous splitting reactor). The term “spatially separated” is understood here to mean the opposite of a homogeneous mixture, namely the “macroscopic” independence of the regions of the fissile substances (fuel regions) and the regions of the neutron scattering substances (moderator regions).

By slowing the fission neutrons to thermal speed in areas which are sufficiently remote from the fissile substance, they are more likely to escape the capture processes which occur particularly at certain mean velocities (resonance regions) of the neutrons. In this way, the multiplication factor for the fission neutrons achieves the critical value 1 for stationary reactor operation, which is also due to the geometric arrangement of the fissionable substances and neutron-scattering substances.

Before the priority date of the invention, the primary neutrons emitted from a Ra-Be preparation had been slowed only in experimental setups in neutron scattering substances spatially separated from the fissile substance (cf. *Comptes Rendus* 208, [1939] p. 898–900). However, before the priority date of the invention, it was not known to provide such an arrangement also for slowing secondary neutrons (fission neutrons) arising in the fissile substance. It was not obvious to moderate (moderate) the secondary neutrons formed in the fissionable substance, which are needed to maintain the chain reaction in the same fissionable substance for further fission reactions, outside the fissionable substance.

Eine weitere Möglichkeit, die Neutronenökonomie zu verbessern, besteht in der erfindungsgemässen Anwendung eines reinen Isotops der Spaltsubstanz mit grossem Spaltungswirkungsquerschnitt für Neutronen, vorzugsweise langsame (thermische) Neutronen bzw. einer mit einem solchen Isotop angereicherten Substanz. Es wurde zwar zum Prioritätszeitpunkt der Erfindung schon vermutet, dass z. B. das Uranisotop 235 das im wesentlichen spaltbare Isotop sei des Urans (vgl. *Naturwissenschaften* 27 [1939], S. 405), jedoch wurden daraus keinerlei technische Massnahmen gefolgert, insbesondere nicht bei räumlicher Trennung von Spaltsubstanz und neutronenstreuenden Substanzen.

Die Kettenreaktion, welche in der erfindungsgemässen Vorrichtung abläuft, kann man auch steuern, sei es durch Nähern oder Entfernen des streuenden Materials (Moderator), sei es durch Beimengung neutronenabsorbierender (aber keine Neutronen liefernden) Substanzen (Absorber), schliesslich dadurch, dass man durch die spezielle geometrische Anordnung der reagierenden Substanzen den Vermehrungsfaktor um ein Geringes kleiner als 1 macht.

Beispiel: Eine dünne Platte aus Uranisotop 235, beiderseits bedeckt von dickeren Paraffinplatten oder etwa gleich von dem Wasser eines zu heizenden Dampfkessels, bestrahlt mit Ra-Be-Neutronen, bildet einen Heizkörper von ungeheurem Wärmevorrat. Der Gefahr der Explosion kann hier schon durch die Verwendung der langsamen Neutronen vorgebeugt werden, da bei entsprechender geometrischer Anordnung der oben erwähnte Vermehrungsfaktor bei einer bestimmten Temperatur unter seinen kritischen Wert 1 sinkt, so dass man geradezu auf eine bestimmte Temperatur einstellen kann.

A further possibility of improving the neutron economy consists in the application according to the invention of a pure isotope of the fissionable substance with a large fission reaction cross-section for neutrons, preferably slow (thermal) neutrons or a substance enriched with such an isotope. Although it was already assumed at the priority date of the invention that the uranium isotope 235 is the essentially fissionable isotope of uranium (cf. *Naturwissenschaften* 27 [1939], p. 405), however, no technical measures were taken from this, especially in the case of spatial separation of fissile substances and neutron-scattering substances.

The chain reaction which proceeds in the apparatus according to the invention can also be controlled, whether by inserting or removing the scattering material (moderator), or by admixing neutron-absorbing (but not neutron-supplying) substances (absorbers), finally, the particular geometric arrangement of the reacting substances makes the multiplication factor a little less than 1.

Example: A thin plate of Uranisotope 235, on either side covered by thicker paraffin plates or already by the water of a boiler to be heated, irradiated with Ra-Be neutrons, forms a radiator of immense heat. The danger of the explosion can already be presented here by the use of the slow neutrons, since, given the corresponding geometrical arrangement, the multiplication factor mentioned above drops below its critical value 1 at a certain temperature, so that it is virtually possible to adjust to a certain temperature.

PATENTANSPRÜCHE:	PATENT CLAIMS:
1. Vorrichtung zur technischen Energiegewinnung mit Hilfe von Kernspaltungsreaktionen, wobei ausser den eigentlichen Spaltsubstanzen (Brennstoff) neutronenstreuende Substanzen (Moderator) und gegebenenfalls neutronenabsorbierende Substanzen (Absorber) verwendet sind, dadurch gekennzeichnet, dass die Spaltsubstanzen (Brennstoff) von den neutronenstreuenden Substanzen (Moderator) räumlich getrennt angeordnet sind.	1. Apparatus for technical energy production by means of nuclear fission reactions, wherein neutron-scattering substances (moderator) and optionally neutron-absorbing substances (absorber) are used in addition to the actual fission substances (fuel), characterized in that the fission substances (fuel) are arranged spatially separate from the neutron-scattering substances (moderator).
2. Vorrichtung nach Anspruch l, dadurch gekennzeichnet, dass als Spaltsubstanz (Brennstoff) ein reines Isotop mit grossem Spaltungswirkungsquerschnitt vorzugsweise für thermische Neutronen, z. B. Uran 235 bzw. eine mit einem solchen Isotop angereicherte Substanz verwendet ist.	2. A device according to claim 1, characterized in that a pure isotope with a large fission reaction cross section, preferably for thermal neutrons, e.g. uranium 235 or a substance enriched with such an isotope, is used as the fission substance (fuel).
3. Vorrichtung nach Anspruch l, dadurch gekennzeichnet, dass als Einheit eine Schicht aus Uran 235 (Brennstoff) beidseitig bedeckt mit dickeren Paraffinschichten (Moderator) verwendet ist.	3. Device according to claim 1, characterized in that a layer of uranium 235 (fuel) is coated as a unit on both sides with thicker paraffin layers (moderator).

[Georg Stetter (Austrian, 1895–1988) led a nuclear physics group at the University of Vienna. In this patent application, Stetter gave a remarkably detailed description of a fission reactor.

See document photos on pp. 3370–3371. For an early 1939 draft of this patent application that also includes fusion reactions, see German nuclear report G-378 (p. 4330).

Austria was part of Germany from 1938 until the end of the war. Stetter and his group apparently played important roles in the wartime German nuclear program (pp. 4330–4345, 4788–4800, 4992).]

Philip Morrison to Samuel K. Allison. 20 December 1943. Report on Enemy Physics Literature: Survey Report P. [NARA RG 77, Entry UD-22A, Box 170, Folder 32.60-1 GERMANY: Summary Reports (1944)]

Several high-voltage machines are in operation. Excluding apparatus below 1 Mev (which may be good neutron sources for many purposes) there are machines: [...]

2) At Berlin-Lichterfelde, in the private laboratory of the radio engineer, M. von Ardenne. At this laboratory some neutron work is being done, and at least one well-known neutron physicist (Houtermans) is employed.(20) It is interesting that an electronic research laboratory should extend into nuclear physics in war-time. Ardenne mentions that he was urged to do nuclear physics in 1939 by the Reichspostminister Ohnesorge. [...]

(Can the presence and scale of secret work of these laboratories be determined?) [...]

(20) Physik. Z., 44, 167 (1943)

David Irving. 1967. *The Virus House*. London: William Kimber.

[p. 33:] The conference took place in all secrecy on 29th April 1939 at the Ministry's [Reich Ministry of Education, in charge of universities] building at Unter den Linden in Berlin.[1] [...]

[1] Those at this first meeting were: Professor [Abraham] Esau (*chairman*); Professors [Georg] Joos, [Wilhelm] Hanle, [Hans] Geiger, [Josef] Mattauch, [Walther] Bothe and [Gerhard] Hoffmann; and the Ministry's representative, Doctor [Wilhelm] Dames.

Professor Esau recommended that they secure at once all available uranium stocks in Germany. [...]

A general ban was placed on the export of uranium compounds from Germany, and negotiations were opened with the Reich Ministry of Economics for the provision of radium from the recently captured mines at Joachimsthal (Jachymov) in Czechoslovakia. [...]

[pp. 38–43:] The letter [from Harteck and Groth on 24 April 1939] had been passed to General Becker's Army Ordnance Department, and thence to the research branch under Professor Erich Schumann. Schumann in turn forwarded it to Doctor Kurt Diebner, the Army's expert on nuclear physics and explosives, and another key figure in this history. [...]

Diebner was at the time 34 years old. He had read nuclear physics at the University of Halle under Professor Pose, and graduated with a thesis on the ionisation [by] alpha rays late in 1931. For a time he had worked at the Bureau of Standards laboratory on the construction of a new high-voltage particle accelerator for atomic transformations; but in 1934 the Army had appointed him to an Ordnance Department research branch where together with Doctor Friedrich Berkei he had investigated hollow-charge explosives—a development similar to one being undertaken by the air force's Professor Schardin at Berlin-Gatow. [...] Doctor Kurt Diebner had at this time a growing reputation in nuclear physics with some twenty publications to his name. [...]

During the summer [of 1939], with further encouragement from Flügge's articles, and in particular from a patent application by the Viennese Professor Stetter for a process for extracting atomic energy, they obtained the first Army funds to start research on uranium and a laboratory was erected at Gottow, a section of the Army's vast Kummersdorf rocket-projectiles and explosives research establishment outside Berlin. An independent nuclear research office was at last opened in the Army Ordnance Department, and Diebner was put in charge. [...]

The energetic steps taken by Esau seem to have stimulated the War Office team to intensify their own efforts. [...] Together with Professor Schumann, Diebner explained that [Erich] Bagge had been sent for to help the War Office arrange an immediate secret conference to decide on the feasibility of a uranium project. Between them, Diebner and Bagge drew up a short list of the physicists and chemists most clearly concerned, including Professor Walther Bothe, Professor Geiger, Professor Stetter, Professor Hoffmann, Professor Mattauch, and Doctors Bagge, Diebner and Flügge. Otto Hahn was also summoned to attend. [...]

The 'important matter' was now a State secret. From this stage on, all reference to the possibilities of uranium reactors and atomic bombs was suppressed. [...I]n general nothing else appeared in print in Germany until 1942 when the impatient nuclear scientists were given permission to publish some of their lesser research papers, provided that no mention of their context was made.

[pp. 70–71:] Early in 1940, Baron Manfred von Ardenne, an outstanding technician in his particular field, tried to persuade Otto Hahn's instrumentation and equipment specialist, Professor Philipp, to apply for a subsidy from General Göring for the construction of large 'atom-smashing' installations. [...]

Von Ardenne cast around for a source of large-scale funds, and learned that the Post Office had a large and rich research department. He called personally on the Minister of Posts, Ohnesorge, and in general terms explained how Hahn's discovery made uranium bombs now possible; he called particular attention to hints about 'powering ships with uranium reactors' dropped in a commentary to the US naval construction programme. In personal exchanges between the Dahlem laboratories and his own laboratory in Lichterfelde, von Ardenne had asked both Hahn and Heisenberg outright how much pure uranium-235 was necessary for an atomic explosion. He was told it would be only a few kilograms. 'During these discussions,' von Ardenne describes, 'I expressed an opinion that it was technically quite feasible, by means of high-yield electromagnetic mass-separators (which we already had on our drawing boards) to make quantities of a few kilograms of uranium-235 available, if only the Reich government would resolve to direct the talents of the big electrical combines to that end.'

Minister Ohnesorge was so impressed by von Ardenne's argument, that he secured an audience with Adolf Hitler soon after, and informed him of the uranium bomb. [...]

Von Ardenne saw Ohnesorge return angry and disappointed, but not defeated: he resolved to support von Ardenne's project within the framework of German Post Office research. There were thus now three factions in the nuclear research effort: the scientists allied to Doctor Diebner—including Berkei, Czulius, Herrmann, Hartwig and Kamin—at the Army Ordnance Department's Gottow laboratory; the scientists attracted to von Ardenne's laboratory; and the institutes of physics of the Kaiser-Wilhelm Foundation.

[Although David Irving was neither a trained historian nor a scientist (and ultimately went off the deep end), his book contains a great deal of useful information since he personally interviewed many of the German nuclear scientists within two decades after the end of the war.

Wilhelm Ohnesorge studied physics at the university before becoming head of the Reichspost. He had a large amount of research funding at his disposal, since his organization collected payments for all letters, packages, and telegrams sent throughout the Third Reich. He used that funding to support very advanced research programs in electronics, and he could have easily used it to support the early years of a nuclear weapons program as well. As reported by Irving, Ohnesorge sought larger amounts of nuclear funding from Hitler and was rejected, at least initially. Yet as also described by Irving, Ohnesorge did not give up easily.

Beginning no later than June 1942, Ohnesorge began a research collaboration with Heinrich Himmler and the SS, which could supply large amounts of funding, personnel, facilities, and other resources (see pp. 3378–3387 for a few surviving documents). In September 1942, Ohnesorge again lobbied Hitler for political and financial support, revealing his knowledge of the U.S. Manhattan Project in the process (p. 3379): "According to his [Ohnesorge's] observations, at the moment America is gathering all the professors of physics and chemistry to produce special achievements. He would like to give a short lecture about this to the Führer." However the further discussions with Hitler turned out, the collaboration between the Reichspost and the SS appears to have continued until the end of the war, with large investments of resources in the program.

Kurt Diebner's research group also appears to have become aligned with the SS as the war progressed.]

Reichsführer !

Über das Reichspostministerium wird mir mitgeteilt, dass in enger Zusammenarbeit der Herren der Versuchsabteilung mit SS-Oberführer Knapp, Kommandoamt der Waffen-SS, in der Hackeburg die ersten Ergebnisse vorhanden sind. Ein in einem Panzer oder Personenwagen einzubauendes fertiges Gerät ist hier in Berlin, könnte also dem Reichsführer-SS und vielleicht auch dem Führer vorgeführt werden.

Die Ergebnisse sind so, dass auf 350 m ein Mann erkannt und beschossen werden kann und dass man ohne Licht mit 80 km Stundengeschwindigkeit auf der Landstrasse fahren kann. Der Reichspostminister wäre sehr dankbar, wenn es ermöglicht werden könnte, dass bei der Vorführung beim Führer auch er eingeladen würde.

Reichsführer !

Reichspostminister Dr. Ohnesorge ist sehr aktiv und sehr beweglich aus seinem Urlaub zurückgekehrt. Drängt gewaltig, zum Führer zu kommen aus folgenden Gründen:

a) Nach seinen Beobachtungen fasst im Augenblick Amerika die gesamten Professoren der Physik und der Chemie zusammen, um besondere Leistungen hervorzubringen. Er möchte hierüber kurz dem Führer Vortrag halten.

b) Dr. Ohnesorge möchte sein nun ausprobiertes Gerät, aufgebaut auf einem Panzerjäger, dem Führer vorführen, um überhaupt die Möglichkeit zu erhalten, es für die Waffen-ᛋᛋ in genügender Menge herstellen lassen zu können. Die Konstrukteure würden selbst in das Führerhauptquartier fahren, das Gerät an einem vorhandenen Fahrzeug, bezw. Geschütz aufbauen, sodass es kurz dem Führer gezeigt werden könnte.

c) Dr. Ohnesorge möchte dem Reichsführer-ᛋᛋ für seinen Kulturfonds einen Scheck über 5 Mill. Mark persönlich übergeben.

Ich wäre in besonderem Masse dankbar, wenn der Besuch von Dr. Ohnesorge im Führerhauptquartier bald ermöglicht werden könnte, jedenfalls vor dem Mitte September beginnenden Europäischen Kongress.

H. Himmler
Berlin SW 11
Prinz Albrechtstr. 8
(über ᛋᛋ-Gruppenführer Berger)

Lieber Parteigenosse Himmler!

Im Juni v.J. führte ich Ihnen in der Forschungsanstalt der Deutschen Reichspost (RPF) Betrachtungsgeräte für unsichtbares Licht (Infrarot) vor. Sie zeigten für diese Entwicklung großes Interesse und schlugen erstmalig vor, diese Geräte bei Panzern für Nachtangriffe und zur Abwehr von nächtlichen Panzerangriffen einzusetzen. Gruppenführer Jüttner beauftragte darauf Oberführer Knapp, Inspekteur der Kraftfahr- und Kraftfahrkampftruppen, mit dem Einsatz der RPF-Geräte. Deshalb fuhr Oberführer Knapp mit dem wissenschaftlichen Mitarbeiter Dr. Fenner im Juli 1942 nach Frankreich, um bei der LSSAH die RPF-Geräte der Truppe vorzuführen, Einbaufragen zu klären und die von der Truppe aus zu stellenden Anforderungen festzulegen. In der darauffolgenden Zeit hat Oberführer Knapp sich sehr energisch bemüht, die Lieferung der notwendigen Zusatz- und Einbauteile zu beschleunigen, auch durch häufige persönliche Besuche bei den betref-

fenden

fenden Stellen, und für die Fertigung der Geräte eine höhere Dringlichkeitsstufe zu erlangen. Bei der Vorführung dieser Geräte durch mich beim Führer am 4.10.42 war Oberführer Knapp als Vertreter der Waffen-ϟϟzugegen.

Weiter hat Oberführer Knapp die RPF-Geräte verschiedenen Stellen der Waffen-ϟϟ, die ebenfalls dieselben verwenden können, vorgeführt, z.B. Gruppenführer Krüger, Brigadeführer Hansen, Oberführer Dr.Schwab, ϟϟ- Waffenamt und Vertretern der ϟϟ -Flakinspektion. Zur planmäßigen Vorbereitung für den Einsatz der Geräte sind auf Veranlasssung von Oberführer Knapp mehrere Gruppen von Männern der KEA Lichterfelde bei der RPF ausgebildet worden, die später bei der Truppe die Geräte betreuen sollen, ferner Spezialfahrzeuge (Maultier) beantragt und besonders ausgestattet worden. Durch seine persönliche Initiative sind besonders Visiere, Zusatzgeräte für Maschinenpistole, Panzerbüchse, leichtes MG und Geräte zum Einbau in Kübelwagen entwickelt worden.

Da sich Oberführer Knapp dieser Aufgaben mit großer Energie und Tatkraft gewidmet hat, ist eine sehr enge Zusammenarbeit zwischen der RPF, Gruppe FE und dem ϟϟ-Kommandoamt entstanden. Durch die Ungültigkeitserklärung der Metallscheine im August ist die Lieferung von Objektiven, Lupen und Einbauteilen um einige Monate hinausgeschoben worden. Diese Schwierigkeiten sind jetzt behoben, so daß in Kürze der Einsatz der Geräte erfolgen kann. Ich würde es daher sehr begrüßen, wenn Oberführer Knapp im Interesse einer engen Zusammenarbeit mit der RPF und der beschleunigten Lieferung der Geräte weiter die Durchführung des Einsatzes der RPF-Geräte bei der Waffen-ϟϟ von Berlin aus leitet.

Mit herzlichen Grüßen
Heil Hitler!
Ihr
Ohnesorge

Lieber Parteigenosse Ohnesorge !

Ich komme erst heute dazu, Ihren Brief vom 11.1.1943 zu beantworten.

Leider kann ich Ihnen Ihren Wunsch nicht erfüllen, da ich ᛋᛋ-Oberführer Knapp inzwischen anderweitig einsetzen mußte.

Über die gute Zusammenarbeit, die ᛋᛋ-Oberführer Knapp mit den Herren Ihrer Dienststelle hatte, freue ich mich besonders. Ich bin überzeugt, daß auch unter dem Nachfolger des ᛋᛋ-Oberführers Knapp die Zusammenarbeit gleich gut ist.

Herzliche Grüße und

Heil Hitler !

Ihr

Abschrift

Der Reichspostminister

Berlin W 66, den 10.2.1944
Leipziger Str. 15

An
den Reichsführer-ᛋᛋ
Herrn Reichsminister des Innern
Heinrich Himmler
Feld-Kommandostelle

Lieber Parteigenosse Himmler!

Nach Ihrem Besuch bei der Forschungsanstalt der Deutschen Reichspost wurde der ᛋᛋ-Oberführer Knapp im September 1942 beauftragt, in gemeinsamer Entwicklungsarbeit mit der Forschungsanstalt der Deutschen Reichspost ein Panzerzielgerät zu schaffen. Die Arbeiten gingen auch im Verlauf einiger Monate soweit vorwärts, daß eine Serie von 12 Versuchgsgeräten zur Erprobung vorlag. Eine größere Serie von 500 Geräten wurde seitens der ᛋᛋ in Auftrag gegeben. Solange noch der ᛋᛋ-Oberführer Knapp als Leiter der Inspektion 6 des ᛋᛋ-Führungshauptamtes sich um die Erprobung der Versuchsgeräte, Beschaffung von Material usw. kümmern konnte, kam das Infrarot-Gerät vorwärts, und es bestand die Aussicht, daß im Winter 1943/44 ein Einsatz der Geräte erfolgen konnte.

Nach dem Weggang des ᛋᛋ-Oberführers Kanpp und Zusammenlegung der Interessen des ᛋᛋ-Waffenamtes mit denen des Heereswaffenamtes trat eine ungeheure Verlangsamung in Weiterentwicklung und Herstellung der Geräte für den Fronteinsatz ein. Um dem Gerät zu einem baldigen Einsatz zu verhelfen, erscheint es dringend notwendig, daß sich ein Offizier mit großem technischen Verständnis und äußerstem persö lichen Einsatz, wie es Her Kanpp bisher gezeigt hat, ganz und gar dieser Sache widmen kann.

Ich bitte Sie daher zu prüfem, ob der ᛋᛋ-Oberführer Knapp nicht baldigst wieder die Betreuung der Infrarotgeräte innerhalb der ᛋᛋ übernehmen kann.

Heil Hitler!
Ihr ergebener
gez. Ohnesorge.

Figure D.64: Hans Kammler. 16 April 1945 telegram [NARA RG 242, Records of the Reich Leader of the Schutzstaffel (SS) and Chief of the German Police, Microfilm 183, NAID 273992206 (https://catalog.archives.gov/id/273992206)]. Note that Werner Grothmann is first on the list.

[NARA RG 238, Microfilm M1270, Interrogation Records Prepared for War Crimes Proceedings at Nuernberg, Roll 24]

[In postwar interrogations, one of Himmler's adjutants stated that Himmler had a panel of top science advisors. Of the eleven advisors named in the document, six were nuclear experts and the other five had expertise that could have been very useful for a nuclear weapons program:

- Erich Schumann (German, 1898–1985) appears first in this list, suggesting that he may have been one of Himmler's most important or most frequent scientific advisors. He ran the nuclear program of the Heereswaffenamt (Army Ordnance Office), was directly involved in designing and testing spherical implosion bombs (pp. 4187–4255), and was closely tied to other programs to develop biological weapons, rockets, etc. [Nagel 2012a].
- Christian Gerthsen (German, 1894–1956) was a top-ranked nuclear physicist (p. 4780) whose wartime activities have never been publicly described.
- Hans Geiger (German, 1882–1945) was one of Germany's earliest nuclear physicists (having invented the Geiger counter in 1908, p. 1518) and had been involved in the wartime German nuclear program at the highest levels since early 1939 (p. 3376).
- Walther Gerlach (German, 1889–1979) was the head scientific administrator of the German nuclear weapons program as well as some other advanced technology programs.
- Rudolf Tomaschek (German, 1895–1966) played an important but currently mysterious role in the wartime German H-bomb development program (p. 4334).
- Fritz Kirchner (German, 1896–1967) was a nuclear physicist who worked with the Heereswaffenamt (Army Ordnance Office) during the war. While the full extent of his wartime activities is unclear from currently available documents, he is known to have worked on particle accelerators, fission reactions, and fusion reactions [G-47, G-101, G-270, G-271, and pp. 3608, 4316, 4521, 3326, 4781].
- Leo von zur Mühlen (German, 1888–1953) was an expert on mining resources in central and eastern Europe, which would have been extremely useful for nuclear and other programs.
- August Schmauß (German, 1877–1954) was an expert on meteorology, which would have been important for planning battles in general, and attacks with weapons of mass destruction in particular.
- Heinrich von Ficker (German/Austrian, 1881–1957) was another authority on meteorology.
- Paul Guthnick (German, 1879–1947) was a noted astronomer; his input might have been useful for planning suborbital ballistic trajectories, teaching intercontinental pilots how to navigate to their targets by the stars, or developing other methods of reaching strategic objectives.
- Otto Heckmann (German, 1901–1983) was another astronomy expert.

SEVENTH ARMY INTERROGATION CENTER
APO 758

NOTES ON HIMMLER AND HIS STAFF
BY WILHELM FUEHRER, ADJ TO HIMMLER
Final Interrogation Report

SOURCE

FUEHRER, Wilhelm, Dr, SS-HPTSTUF (Capt) of ALLGEMEINE-SS and O/LT (1st Lt) of WAFFEN-SS; one of HIMMLER's adjutants.

Source is an intellectual idealist who had great faith in Nazi principles and teachings. The new political system became a form of religion for him; he could see only good in it and was blind to any wrong that the Party or its members committed. In spite of his close connection with HIMMLER and the SS, he claims to have no knowledge of any crimes committed by this man or his followers. He states that it would be difficult for him to forget or give up his beliefs of the past.

Rating: C-3   **Date of Information**: See Text   **Interrogator**: F.T.M.

PERSONAL HISTORY

1904	Born in RUESTRINGEN, Oldenburg.
25-30	Studied astronomy, physics, physical education.
30	Joined NSDAP, KIEL.
30-33	Staff of ASTRONOMISCHE NACHRICHTEN (Astronomical News); worked at KIEL observatory.
31-32	BLOCKWALTER (Local Party administrator), ORTSGRUPPE MITTE (Party District Center), KIEL.
33	Joined SS.
33-36	Assistant at Observatory, MUNICH.
34-39	Superintendant of secondary schools, MUNICH, with membership in National Socialist Teacher's and Professor's organization.
35	With 19 Inf Regt, FREISING, for tng.
36-39	REGIERUNGSRAT (Govt counsellor) and REGIERUNGSRAT 1.Kl., Bavarian Ministry of Education and Culture.
36	USTUF (2nd Lt), ALLGEMEINE-SS, SS Hq, MUNICH.
39	With DAS AHNENERBE (instruction and research society), a part of REICHSFUEHRUNG SS (SS High Command). REGIERUNGSRAT (Govt Counsellor), and then OBERREGIERUNGSRAT (Senior Govt Counsellor), REICHS Ministry for Science and Culture.
Jan 42	Promoted to OSTUF (1st Lt), ALLGEMEINE-SS.
Aug 42	STURMMANN (Pvt), WAFFEN-SS; attached as USTUF-FACH (specialist) to field branch of REICHSFUEHRUNG-SS, where he instructed HIMMLER in astronomy.

Jan 44	Promoted to HPTSTUF (Capt), ALLGEMEINE-SS.
May-Jul 44	OSCHAF(S/Sgt)of WAFFEN-SS, 1 SS AA Bn, Central Russia.
22 Apr- 4 May 45	At SALZBURG-AIGEN SS Hq, having left HIMMLER's CP at WUSTRAU, near BERLIN.
15 May 45	Arrested by CIC at wife's apartment, REITGUTWEG 10, SALZBURG-AIGEN.

1. ACTIVITY AS HIMMLER'S ADJUTANT

Source's duties as adj to HIMMLER consisted almost entirely of providing personal services - quarters, entertainment, transportation, etc - for HIMMLER's guests. His execution of these duties was so pleasing to HIMMLER and his guests that source retained the position throughout the war years, except for brief periods of military training.

PW mentioned the following persons as frequent guests of HIMMLER: FUNK, SPEER, NAUMANN, DOENITZ, JODL, WARLIMONT, PUTTKAMMER,BAUMBACH, GUDERIAN, ZEITZLER, and the Gauleiters KOCH, FOSTER, HANKE and GREISER. In his last CP, at ZIETHEN Castle, WUSTRAU (NW of BERLIN), HIMMLER received the following guests:

BODIN	Manufacturer of the PANZERFAUST
POHL, SS-OGRUF (Lt Gen)	Chief of WIRTSCHAFTS- UND VERWALTUNGS-AMT(Economic and Administration Office)
HILDENBRAND, SS-OGRUF (Lt Gen)	SS and Police Chief of Silesia

2. HIMMLER'S DOCUMENTS AND VALUABLES

a. Locations

CP, SALZBURG) CP, WUSTRAU)	All documents at these CP's were burned, source claims.
Alternate CP, FRANKENHAUSEN, Thuringia	Taken by American forces early in Apr. Most important files were here.
WEWELSBURG Castle, near PADERBORN, Westphalia	Many valuables were stored here.
Old salt mines, HALLEIN (S of SALZBURG)	Personal property belonging to HIMMLER was stored here.
HIMMLER's house, LINDENFYCHT,GMUND/TEGERNSEE	BAUMERT (See below) told source no property had been removed from here.

b. Source believes that SS-OGRUF (Lt Gen) WOLF, SS and Police Chief, Italy, has information concerning HIMMLER's documents and property. WOLF was in BOZEN 4 May 45. Source also believes that SS-STAF (Col) BAUMERT (See 4b below) has information on this subject.

3. HIMMLER AND ASTRONOMY

Source claims that HIMMLER was a believer in Glacial Cosmogony. By converting the common man to this belief, he hoped to save him from the "illusions" preached by Christianity. To further his aims, HIMMLER wanted to make it possible for everyone to observe the phe-

Figure D.66: In postwar interrogations, one of Himmler's adjutants stated that Himmler had a panel of top science advisors, including Walther Gerlach, Erich Schumann, and other nuclear scientists [NARA RG 238, Microfilm M1270, Interrogation Records Prepared for War Crimes Proceedings at Nuernberg, Roll 24].

nomena of the universe, especially the stars. He hoped to establish small observatories in SS schools and camps, and also planned to produce telescopes and microscopes in bulk at popular prices.

4. PERSONALITIES

a. HIMMLER's Field Hq

GROTHMANN, SS-OSTUBAF (Lt Col)	Adj to HIMMLER from 1941 to the last; supervised military matters of WAFFEN-SS. Born HAMBURG; 29 years old; blue eyes, 1,75 m tall.
BRANDT, Dr Jur, STAF (Col) of ALLGEMEINE SS, OSCHAF (Sgt) of WAFFEN-SS	With HIMMLER for the last ten years. Was HIMMLER's personal secretary; contact man with SS HAUPTAEMTER (main offices). In charge of non-military mail. Born FRANKFURT/ODER; 35 years old; dark hair, brown eyes, 1,70 m tall.
SUCHANEK, Lt Col of Police	With HIMMLER for ten years. Adj for police matters. Went to SALZBURG-AIGEN 20 Apr 45 to meet WUNNENBERG, OGRUF (Lt Gen), Chief of Order Police (ORDNUNGSPOLIZEI). SUCHANEK was born BERLIN; 37 years old; blond, blue eyes; 1,75 m tall.
BENDER, SS-STAF (Col)	Judge; advisor on SS-HAUPTAMT (Central Dept of SS) decisions which were passed on by HIMMLER. Went to SALZBURG-AIGEN 20 Apr; left for BERCHTESGADEN 3 May. Born LYCK, E Prussia; 40 years old; dark hair; 1,80 m tall.
WEHSER, SS-STUBAF (Maj) GIESSELMANN, SS-STUBAF (Maj)	Temporarily in Field Hq, working under BENDER.
KIERMEIER, STUBAF (Maj)	Chief of REICHSSICHERHEITSDIENST (National Dept of Security). In charge of HIMMLER's personal security. Born MUNICH; 50 years old; blue eyes; 1,80 m tall.
SEIBERT, OSTUF (1st Lt) SCHMIDT, OSTUF (1st Lt) LORENZ, USTUF (2nd Lt) MUELLER, OSCHAF (S/Sgt)	Worked with KIERMEIER
TIEFENBACHER, SS-STUBAF (Maj)	In charge of HIMMLER's quarters. Born MUNICH; 44 years old; dark hair, brown eyes; 1,76 m tall.

SCHMALOER, SS-STUBAF (Maj)	Chief of radio, telephone, teletype sec of field Hq. Born Westphalia; 30 years old; dark blond, blue eyes; 1,80 m tall.
MUELLER, Dr	HIMMLER's physician. Born vic MUNICH; 35 years old; blond, blue eyes;1,78 m tall.
KERSTEN, Dr (Cf Report Ref No SAIC/15, 22 May 45)	HIMMLER's physician in special instances. Citizen of Germany, Finland and Holland.

b. HIMMLER'S BERLIN Hq

BAUMERT, SS-STAF (Col) (See above, 2b)	In SALZBURG-AIGEN at end Apr; then flew to BERLIN. Born Silesia; 42 years old; blond, blue eyes, 1,70 m tall.
REICHENBERGER, SS-OSTUF (1st Lt)	Adj to HIMMLER. In Swabia at end April. Thirty years old; dark hair brown eyes;1,70 m tall.
GUTGESELL, SS-HPTSTUF (Capt)	Adm officer. Probably in Swabia at end April. Fifty years old; dark hair, blue eyes;1,75 m tall.
BREITFELDT, SS-STUBAF (Maj)	Pers officer. Rumored killed or captured in FRANKENHAUSEN, Thuringia. Blond, blue eyes; 1,90 m tall.
SCHNITZLER,SS-HPTSTUF (Capt)	Adm officer. Probably in Swabia at end April. Forty years old; dark hair, brown eyes; 1,75 m tall
BETHGE, Mrs	HIMMLER's stenographer, 1941-43 Husband was manager Hotel RUSSISCHER HOF.
MAENNER, Miss	HIMMLER's stenographer, 1943 on. Seen at WUSTRAU Hq 20 Apr. From MUNICH.

c. Scientific Personalities

SCHUMANN, Prof	Director, First Physics Institute, University of BERLIN, and of HEERESWAFFENAMT (Army Ord Dept).
GERTHSEN, Prof	Director, Second Physics Institute University of BERLIN; atom research.
GEIGER, Prof	Director, Physics Institute, TECHNISCHE HOCHSCHULE (Technical College), BERLIN;atom research.
GERLACH, Prof	Physics Institute, University of MUNICH.

HECKMANN, Prof	Director, Observatory, HAMBURG-BERGEDORF.
KIRCHNER, Prof	Director, Physics Institute, University of COLOGNE. Expert on atom physics.

5. HIMMLER'S CP LOCATIONS

At end Nov 44, when HIMMLER took command of Army Group OBERRHEIN, his CP was transferred from East Prussia to the SCHWARZWALD (Black Forest). When he became commander of Army Group WEICHSEL, his CP was again transferred to the east. At end Mar 44, Gen HEINRICI took over Army Group WEICHSEL, and HIMMLER's CP was moved to its last location, ZIETHEN Castle, WUSTRAU.

6. HIMMLER AND OSHIMA

It was rumored at HIMMLER's Hq that OSHIMA, the Japanese Ambassador to Germany, was trying to bring about a peace settlement between Germany and Russia. Source believes that the primary purpose of OSHIMA's visit to HIMMLER in Aug 44 was to win him over to this plan. It was considered improbable that HIMMLER would agree to this, since he was fanatically opposed to Russia. He was said, however, to have sent peace overtures to the Western Allies via Sweden. His intermediary in Sweden supposedly was Dr KERSTEN. (See 4a, above)

7. Concentration Camp FUENFTEICHEN

In Nov 44 source visited the camp, which was in Lower Silesia and was commanded by SS-STUBAF (Maj) STOPPEL. Source describes the camp as "clean, with hygienic barracks, wash and bathing rooms". Medical care was provided by six Hungarian doctors. There were 6000 inmates, who worked in a nearby KRUPP factory which produced 50 percent of the total output of an unspecified type of gun.

Bundesarchiv, Bild 101III-Alber-064-27A
Foto: Alber, Kurt | 1943

Figure D.70: Werner Grothmann with Heinrich Himmler (1943).

Heinrich Himmler's adjutant Werner Grothmann, transcript of interview by Wolf Krotzky [Krotzky 2002]

[Werner Grothmann (German, 1915–2002) was the chief adjutant or executive assistant of Heinrich Himmler (see pp. 3392, 3395). At the end of his life, during 2000–2002, Grothmann agreed to a series of interviews with Wolf Krotzky, one of his neighbors. Krotzky recorded the interviews on tapes and transcribed Grothmann's words in an unpublished document that is available in the archives of the Jonastalverein in Arnstadt. In the transcripts, Grothmann provided very important details about secret wartime German programs to develop nuclear weapons and improved rockets. Unfortunately, Krotzky said that he did not save the tapes,[5] and Grothmann is now dead and unable to confirm the information in the transcripts.

Without the recorded tapes or Grothmann himself, one cannot rule out the possibilities that Krotzky may have improperly prompted the elderly Grothmann to say certain things that he did not really mean, that Krotzky may have altered the transcripts after the fact, or that Krotzky may have even made up all the transcripts. Furthermore, even if Krotzky and the transcripts were trustworthy, there is no guarantee that Grothmann was trustworthy—his memories may have been incorrect after so long, or he may have had a personal motivation to make false claims about the past.

However, since so few sources are currently available regarding the most secretive details of the wartime German nuclear and advanced rocket programs, and the details provided by Grothmann would be extremely useful if they are real, it is important not to reject this source without careful consideration. In fact, there are many different lines of evidence that suggest that this source is indeed real and accurate (or as accurate as one could expect for a person's recollections so long after the events):

- Historians have been able to independently confirm a large number of details about people, places, dates, and events mentioned in the interviews that are so obscure they would probably not have been independently known by Krotzky [see for example: Karlsch and Petermann 2007, p. 29; Karlsch 2006; Nagel 2011, p. 64].

- Grothmann provided details of the March 1945 test explosion in Thuringia that are in excellent agreement with Ilyichev's March 1945 report to Stalin (see p. 4485), which was discovered in a Moscow archive only after Grothmann had already died.

- Grothmann's statements agree with many other sources about the secret wartime programs that have only emerged in recent years.

- Although Grothmann was not a scientist or engineer and recounted events and discussions from long ago, the scientific details that he mentioned are very consistent with known physics and engineering principles.

---

[5] Perhaps because they were reused to record each interview, and then later unrelated interviews? Or might Krotzky have been pressured by government officials who wanted to keep state secrets?

- In the transcript, Grothmann repeatedly said that he did not know many of the details of the programs, either because he did not have a need to know such classified details in his daily secretarial duties for Himmler, or else because he had forgotten some details over time. If Grothmann or Krotzky had been making up a story, one would have expected the narrator to claim a comprehensive and accurate knowledge of the secret programs, so it is reassuring that Grothmann did not.

- Grothmann frequently described various weapon systems as being unready, imperfect, or unproven by the end of the war. If he were making up a story, one would have expected him to make grander and more dramatic claims for wartime German accomplishments, so again, it is reassuring that he did not.

- In the transcript, Grothmann repeatedly mentioned bureaucratic obstacles, bad decisions, and political disagreements, from Hitler on down through the government. This demonstrates that Grothmann was not trying to make up a story to paint Hitler and the rest of the Third Reich in a positive light.

The complete Grothmann interview transcript is very long and unstructured (see for example pp. 3398–3399). I have translated some of the most relevant excerpts from the transcript, grouped them by topic, and placed them in the appropriate sections of this book. Those topics and page numbers are:

Research on nuclear propulsion for submarines (p. 1474).

Development of transistors and other microelectronics (p. 3017).

Secrecy of the German nuclear program (p. 3400).

Organization of the German nuclear program (pp. 3401–3403).

Enrichment of ^{235}U (pp. 3708–3709).

Fission reactor breeding of ^{239}Pu or ^{233}U (pp. 3865–3866).

Electronuclear (particle accelerator) breeding of ^{239}Pu or ^{233}U (pp. 4024–4025).

Nuclear weapon designs (pp. 4271–4273).

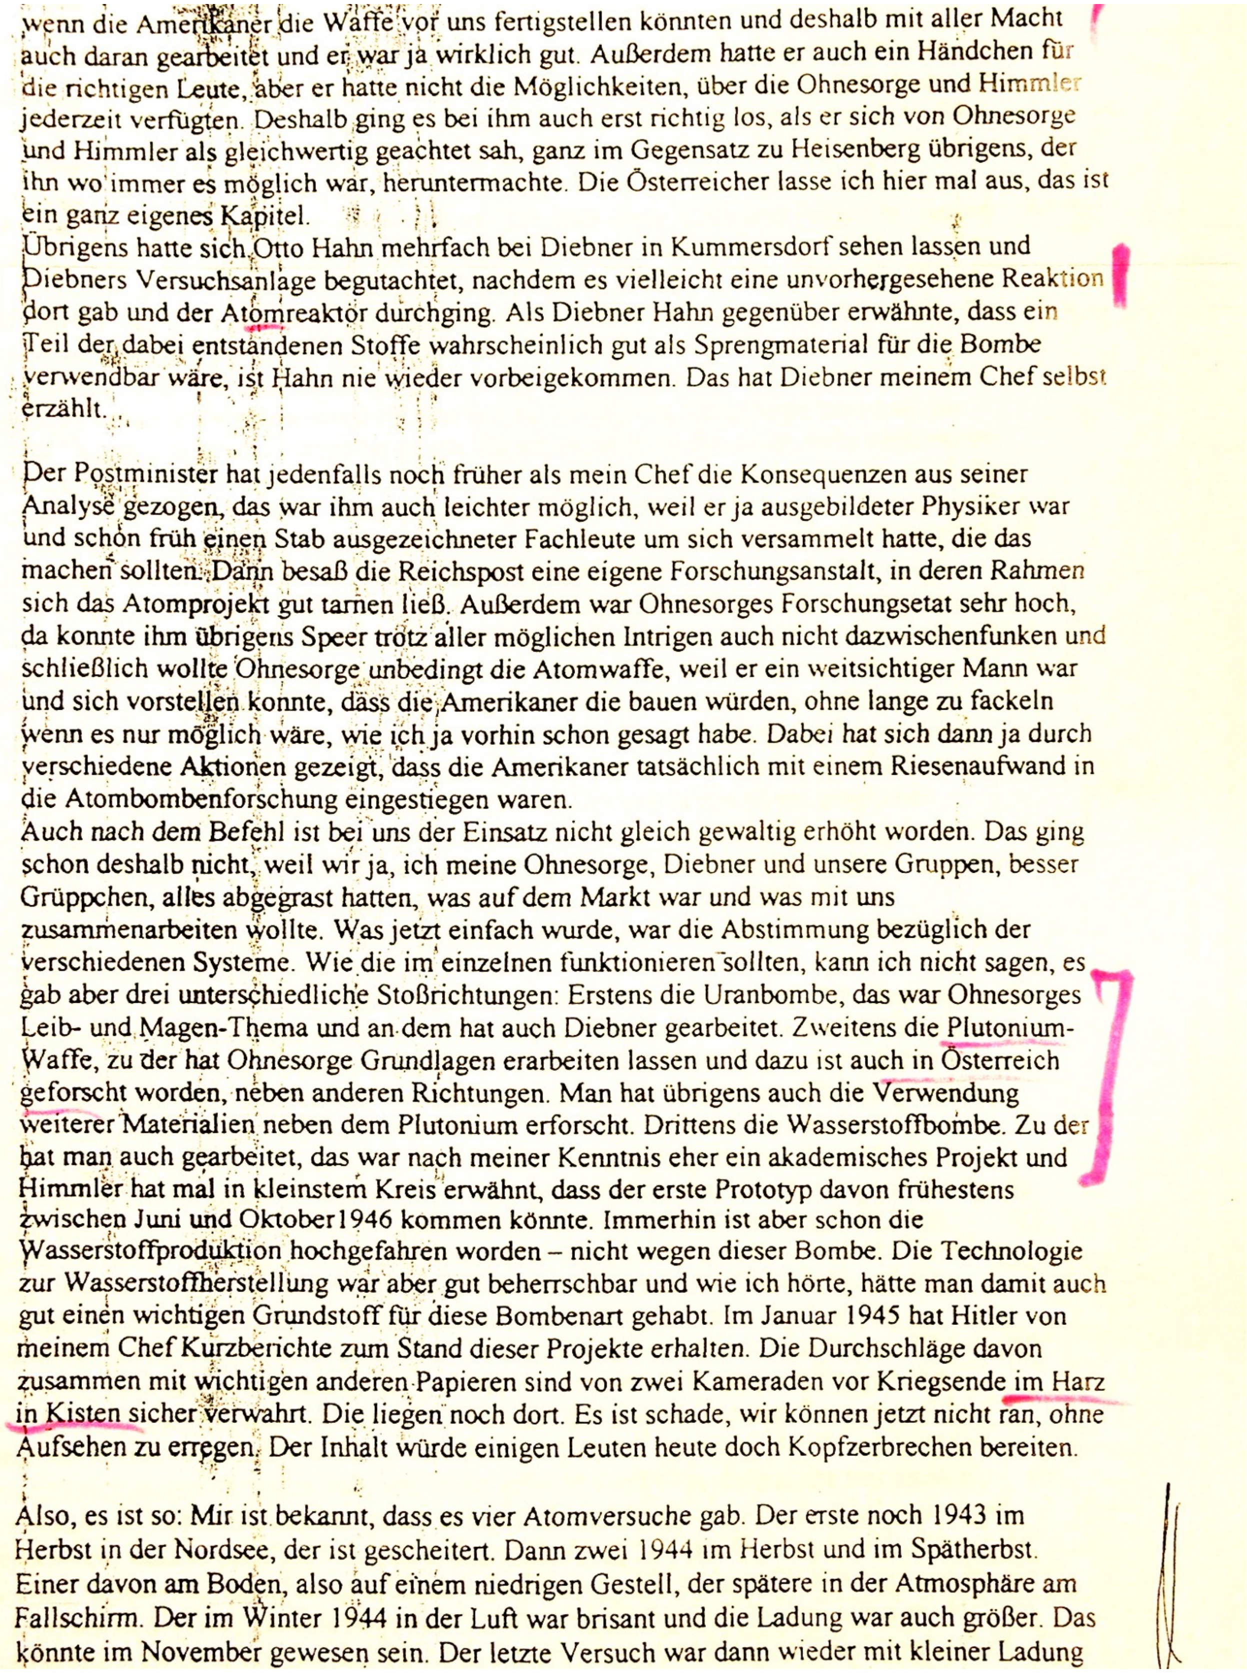
Nuclear weapon tests (pp. 4436–4439).

Reasons why German nuclear weapons were not used in combat (pp. 4668–4669).

Transfer of German nuclear technologies (pp. 5040–5043).

Development of rockets larger than the A-4/V-2 (pp. 5355–5359).

Research on nuclear propulsion for aircraft and rockets (p. 5769).]



wenn die Amerikaner die Waffe vor uns fertigstellen könnten und deshalb mit aller Macht auch daran gearbeitet und er war ja wirklich gut. Außerdem hatte er auch ein Händchen für die richtigen Leute, aber er hatte nicht die Möglichkeiten, über die Ohnesorge und Himmler jederzeit verfügten. Deshalb ging es bei ihm auch erst richtig los, als er sich von Ohnesorge und Himmler als gleichwertig geachtet sah, ganz im Gegensatz zu Heisenberg übrigens, der ihn wo immer es möglich war, heruntermachte. Die Österreicher lasse ich hier mal aus, das ist ein ganz eigenes Kapitel.

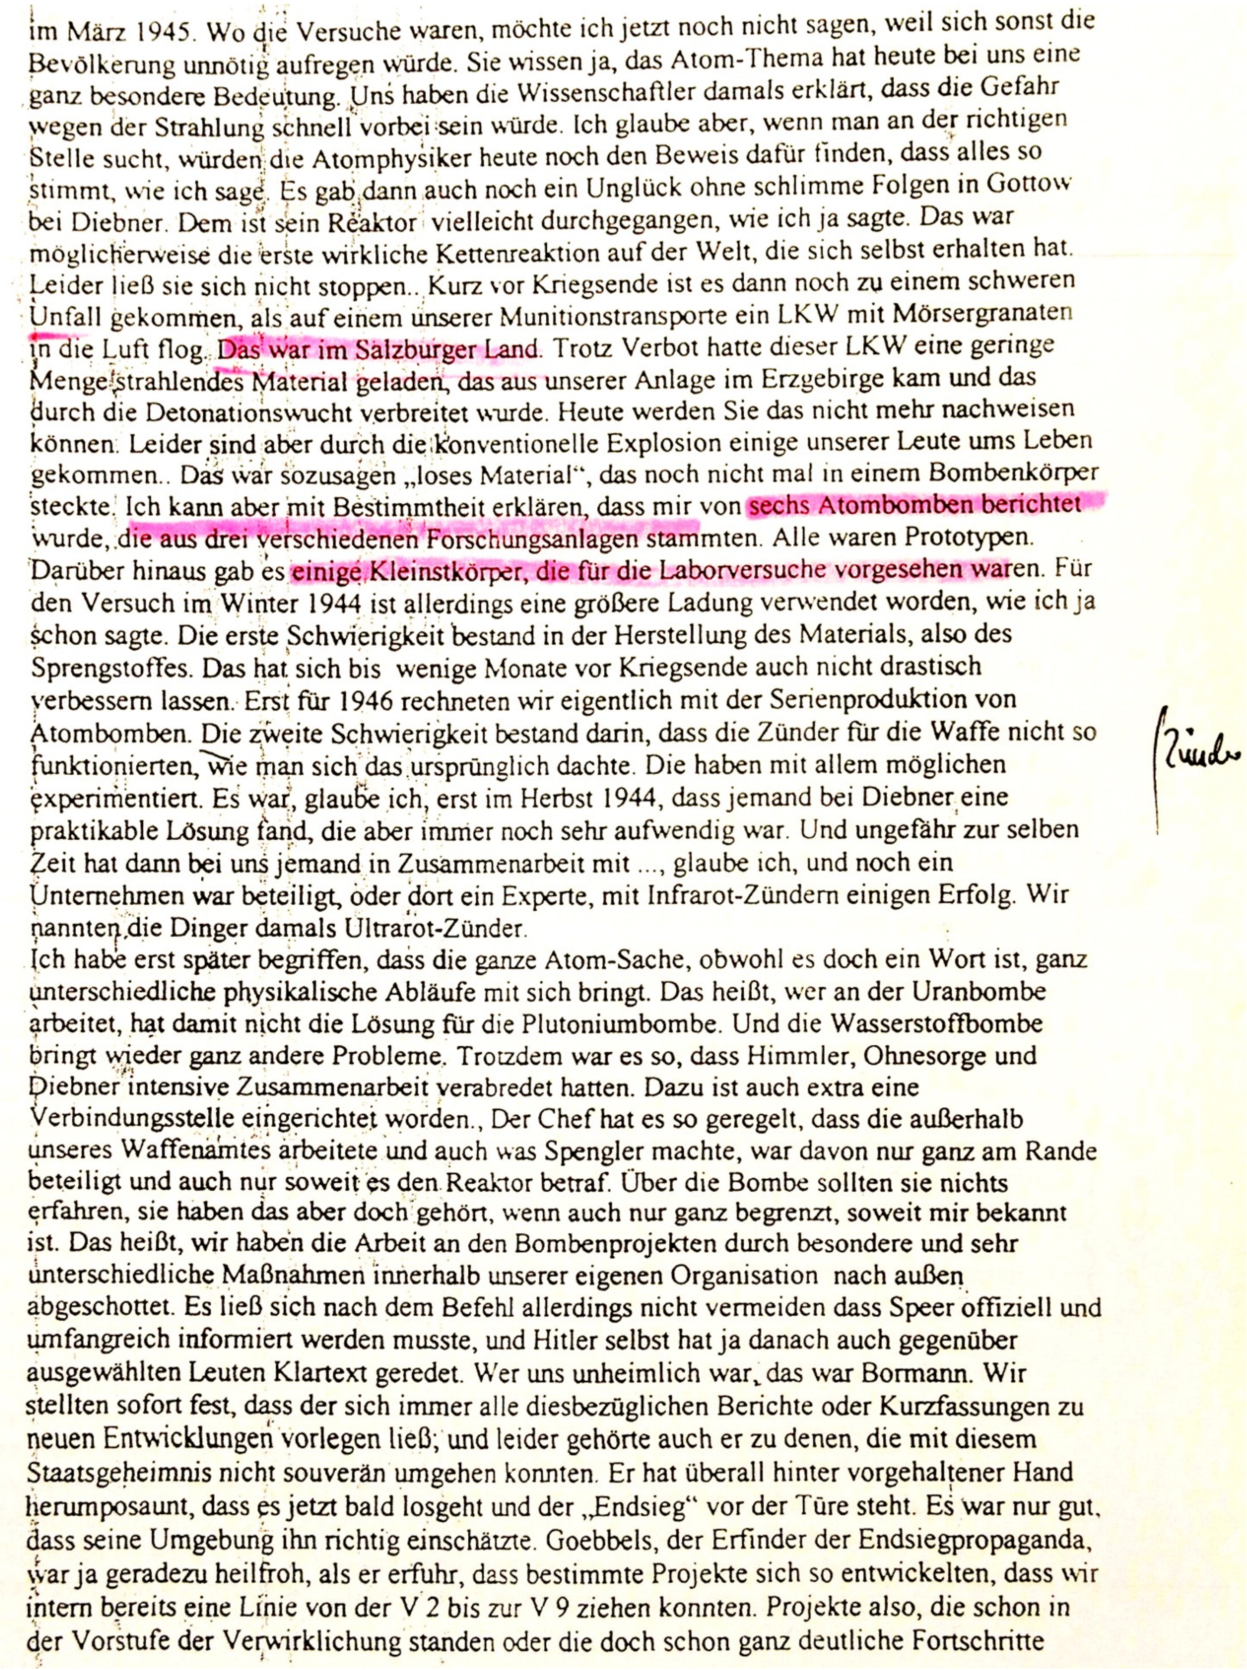
Übrigens hatte sich Otto Hahn mehrfach bei Diebner in Kummersdorf sehen lassen und Diebners Versuchsanlage begutachtet, nachdem es vielleicht eine unvorhergesehene Reaktion dort gab und der Atomreaktor durchging. Als Diebner Hahn gegenüber erwähnte, dass ein Teil der dabei entstandenen Stoffe wahrscheinlich gut als Sprengmaterial für die Bombe verwendbar wäre, ist Hahn nie wieder vorbeigekommen. Das hat Diebner meinem Chef selbst erzählt.

Der Postminister hat jedenfalls noch früher als mein Chef die Konsequenzen aus seiner Analyse gezogen, das war ihm auch leichter möglich, weil er ja ausgebildeter Physiker war und schon früh einen Stab ausgezeichneter Fachleute um sich versammelt hatte, die das machen sollten. Dann besaß die Reichspost eine eigene Forschungsanstalt, in deren Rahmen sich das Atomprojekt gut tarnen ließ. Außerdem war Ohnesorges Forschungsetat sehr hoch, da konnte ihm übrigens Speer trotz aller möglichen Intrigen auch nicht dazwischenfunken und schließlich wollte Ohnesorge unbedingt die Atomwaffe, weil er ein weitsichtiger Mann war und sich vorstellen konnte, dass die Amerikaner die bauen würden, ohne lange zu fackeln wenn es nur möglich wäre, wie ich ja vorhin schon gesagt habe. Dabei hat sich dann ja durch verschiedene Aktionen gezeigt, dass die Amerikaner tatsächlich mit einem Riesenaufwand in die Atombombenforschung eingestiegen waren.

Auch nach dem Befehl ist bei uns der Einsatz nicht gleich gewaltig erhöht worden. Das ging schon deshalb nicht, weil wir ja, ich meine Ohnesorge, Diebner und unsere Gruppen, besser Grüppchen, alles abgegrast hatten, was auf dem Markt war und was mit uns zusammenarbeiten wollte. Was jetzt einfach wurde, war die Abstimmung bezüglich der verschiedenen Systeme. Wie die im einzelnen funktionieren sollten, kann ich nicht sagen, es gab aber drei unterschiedliche Stoßrichtungen: Erstens die Uranbombe, das war Ohnesorges Leib- und Magen-Thema und an dem hat auch Diebner gearbeitet. Zweitens die Plutonium-Waffe, zu der hat Ohnesorge Grundlagen erarbeiten lassen und dazu ist auch in Österreich geforscht worden, neben anderen Richtungen. Man hat übrigens auch die Verwendung weiterer Materialien neben dem Plutonium erforscht. Drittens die Wasserstoffbombe. Zu der hat man auch gearbeitet, das war nach meiner Kenntnis eher ein akademisches Projekt und Himmler hat mal in kleinstem Kreis erwähnt, dass der erste Prototyp davon frühestens zwischen Juni und Oktober1946 kommen könnte. Immerhin ist aber schon die Wasserstoffproduktion hochgefahren worden – nicht wegen dieser Bombe. Die Technologie zur Wasserstoffherstellung war aber gut beherrschbar und wie ich hörte, hätte man damit auch gut einen wichtigen Grundstoff für diese Bombenart gehabt. Im Januar 1945 hat Hitler von meinem Chef Kurzberichte zum Stand dieser Projekte erhalten. Die Durchschläge davon zusammen mit wichtigen anderen Papieren sind von zwei Kameraden vor Kriegsende im Harz in Kisten sicher verwahrt. Die liegen noch dort. Es ist schade, wir können jetzt nicht ran, ohne Aufsehen zu erregen. Der Inhalt würde einigen Leuten heute doch Kopfzerbrechen bereiten.

Also, es ist so: Mir ist bekannt, dass es vier Atomversuche gab. Der erste noch 1943 im Herbst in der Nordsee, der ist gescheitert. Dann zwei 1944 im Herbst und im Spätherbst. Einer davon am Boden, also auf einem niedrigen Gestell, der spätere in der Atmosphäre am Fallschirm. Der im Winter 1944 in der Luft war brisant und die Ladung war auch größer. Das könnte im November gewesen sein. Der letzte Versuch war dann wieder mit kleiner Ladung

Figure D.71: A page from the interview of Werner Grothmann [Krotzky 2002, p. 31, Jonastalverein Archive, Arnstadt].



im März 1945. Wo die Versuche waren, möchte ich jetzt noch nicht sagen, weil sich sonst die Bevölkerung unnötig aufregen würde. Sie wissen ja, das Atom-Thema hat heute bei uns eine ganz besondere Bedeutung. Uns haben die Wissenschaftler damals erklärt, dass die Gefahr wegen der Strahlung schnell vorbei sein würde. Ich glaube aber, wenn man an der richtigen Stelle sucht, würden die Atomphysiker heute noch den Beweis dafür finden, dass alles so stimmt, wie ich sage. Es gab dann auch noch ein Unglück ohne schlimme Folgen in Gottow bei Diebner. Dem ist sein Reaktor vielleicht durchgegangen, wie ich ja sagte. Das war möglicherweise die erste wirkliche Kettenreaktion auf der Welt, die sich selbst erhalten hat. Leider ließ sie sich nicht stoppen.. Kurz vor Kriegsende ist es dann noch zu einem schweren Unfall gekommen, als auf einem unserer Munitionstransporte ein LKW mit Mörsergranaten in die Luft flog. Das war im Salzburger Land. Trotz Verbot hatte dieser LKW eine geringe Menge strahlendes Material geladen, das aus unserer Anlage im Erzgebirge kam und das durch die Detonationswucht verbreitet wurde. Heute werden Sie das nicht mehr nachweisen können. Leider sind aber durch die konventionelle Explosion einige unserer Leute ums Leben gekommen.. Das war sozusagen „loses Material", das noch nicht mal in einem Bombenkörper steckte. Ich kann aber mit Bestimmtheit erklären, dass mir von sechs Atombomben berichtet wurde, die aus drei verschiedenen Forschungsanlagen stammten. Alle waren Prototypen. Darüber hinaus gab es einige Kleinstkörper, die für die Laborversuche vorgesehen waren. Für den Versuch im Winter 1944 ist allerdings eine größere Ladung verwendet worden, wie ich ja schon sagte. Die erste Schwierigkeit bestand in der Herstellung des Materials, also des Sprengstoffes. Das hat sich bis wenige Monate vor Kriegsende auch nicht drastisch verbessern lassen. Erst für 1946 rechneten wir eigentlich mit der Serienproduktion von Atombomben. Die zweite Schwierigkeit bestand darin, dass die Zünder für die Waffe nicht so funktionierten, wie man sich das ursprünglich dachte. Die haben mit allem möglichen experimentiert. Es war, glaube ich, erst im Herbst 1944, dass jemand bei Diebner eine praktikable Lösung fand, die aber immer noch sehr aufwendig war. Und ungefähr zur selben Zeit hat dann bei uns jemand in Zusammenarbeit mit ..., glaube ich, und noch ein Unternehmen war beteiligt, oder dort ein Experte, mit Infrarot-Zündern einigen Erfolg. Wir nannten die Dinger damals Ultrarot-Zünder.

Zünder

Ich habe erst später begriffen, dass die ganze Atom-Sache, obwohl es doch ein Wort ist, ganz unterschiedliche physikalische Abläufe mit sich bringt. Das heißt, wer an der Uranbombe arbeitet, hat damit nicht die Lösung für die Plutoniumbombe. Und die Wasserstoffbombe bringt wieder ganz andere Probleme. Trotzdem war es so, dass Himmler, Ohnesorge und Diebner intensive Zusammenarbeit verabredet hatten. Dazu ist auch extra eine Verbindungsstelle eingerichtet worden., Der Chef hat es so geregelt, dass die außerhalb unseres Waffenamtes arbeitete und auch was Spengler machte, war davon nur ganz am Rande beteiligt und auch nur soweit es den Reaktor betraf. Über die Bombe sollten sie nichts erfahren, sie haben das aber doch gehört, wenn auch nur ganz begrenzt, soweit mir bekannt ist. Das heißt, wir haben die Arbeit an den Bombenprojekten durch besondere und sehr unterschiedliche Maßnahmen innerhalb unserer eigenen Organisation nach außen abgeschottet. Es ließ sich nach dem Befehl allerdings nicht vermeiden dass Speer offiziell und umfangreich informiert werden musste, und Hitler selbst hat ja danach auch gegenüber ausgewählten Leuten Klartext geredet. Wer uns unheimlich war, das war Bormann. Wir stellten sofort fest, dass der sich immer alle diesbezüglichen Berichte oder Kurzfassungen zu neuen Entwicklungen vorlegen ließ; und leider gehörte auch er zu denen, die mit diesem Staatsgeheimnis nicht souverän umgehen konnten. Er hat überall hinter vorgehaltener Hand herumposaunt, dass es jetzt bald losgeht und der „Endsieg" vor der Türe steht. Es war nur gut, dass seine Umgebung ihn richtig einschätzte. Goebbels, der Erfinder der Endsiegpropaganda, war ja geradezu heilfroh, als er erfuhr, dass bestimmte Projekte sich so entwickelten, dass wir intern bereits eine Linie von der V 2 bis zur V 9 ziehen konnten. Projekte also, die schon in der Vorstufe der Verwirklichung standen oder die doch schon ganz deutliche Fortschritte

Figure D.72: A page from the interview of Werner Grothmann [Krotzky 2002, p. 32, Jonastalverein Archive, Arnstadt].

Werner Grothmann on the secrecy of the nuclear program [Krotzky 2002]

[S. 1] Bloß war es so, dass die einzelnen Bearbeiter eines Projekts nicht über Dinge informiert wurden, die sie nichts angingen. Ich habe lange nach dem Krieg mal gelesen, wie die Amerikaner ihre Forschung und Entwicklung organisiert hatten. Ich glaube, das war besser und wirkungsvoller als bei uns. Vielleicht hatten die ja nicht solche Sorge vor Verrat, obwohl es den bei ihnen auch gab. Aber wenn man bedenkt, wie es bei uns geregelt war und dann sieht, wie viel trotzdem verraten wurde, glaube ich, dass durch die besondere Abschottung bei speziellen Projekten doch manches verzögert wurde. Bei der Atomforschung hatten wir ja extra eine Koordinierungsstelle eingerichtet. Das soll sich bewährt haben, wie ich hörte.

[S. 6] Wenn man sich überlegt, warum die Wissenschaftler und Techniker geschwiegen haben, muß man sehen, dass ja längst nicht alle, die an der Atombombe gearbeitet haben, auch erfahren mussten, wie weit die Entwicklung überhaupt kam. Ich kenne die Zahl nicht, es sind aber bestimmt nicht sehr viele gewesen, die das gesamte Geheimnis kannten.

[p. 1] It was just that the individual workers on a project were not informed about things that did not concern them. Long after the war, I read about how the Americans had organized their research and development. I think [their organization] was better and more effective than ours. Perhaps they did not have such concern about treason, although there was also some with them. But when you consider, how it was protected by us and then see how much was nevertheless betrayed, I believe that by the special security in special projects some things were delayed. In nuclear research, we had set up a special coordination center. That would have proved itself, as I have heard.

[p. 6] If you consider why the scientists and technicians were silent, you have to see that not all those who worked on the atomic bomb needed at all to know how far the development came. I do not know the number, but there were certainly not very many who knew the whole secret.

[Grothmann stated that the nuclear program was highly compartmentalized, with every person who was involved only knowing as much information as they absolutely needed in order to do their job. The wartime German chemical weapons program operated in this same fashion [Tucker 2006]. Grothmann repeatedly mentioned how little even he knew about the program. This extreme secrecy would help explain why so little information about the nuclear program leaked out during the war or in the years since.]

Werner Grothmann on the organization of the nuclear program [Krotzky 2002]

[S. 29] Außerdem hatten wir ja bereits Ende 1943 wenn zunächst auch ganz bescheiden, mit unserem eigenen Atomprojekt begonnen, während doch Diebner, Ohnesorge und die Österreicher viel früher gestartet waren.

[S. 31] Auch nach dem Befehl ist bei uns der Einsatz nicht gleich gewaltig erhöht worden. Das ging schon deshalb nicht, weil wir ja, ich meine Ohnesorge, Diebner und unsere Gruppen, besser Grüppchen, alles abgegrast hatten, was auf dem Markt war und was mit uns zusammenarbeiten wollte. Was jetzt einfach wurde, war die Abstimmung bezüglich der verschiedenen Systeme. Wie die im einzelnen funktionieren sollten, kann ich nicht sagen, es gab aber drei unterschiedliche Stoßrichtungen:

Erstens die Uranbombe, das war Ohnesorges Leib- und Magen-Thema und an dem hat auch Diebner gearbeitet.

Zweitens die Plutonium-Waffe, zu der hat Ohnesorge Grundlagen erarbeiten lassen und dazu ist auch in Österreich geforscht worden, neben anderen Richtungen. Man hat übrigens auch die Verwendung weiterer Materialien neben dem Plutonium erforscht.

Drittens die Wasserstoffbombe. Zu der hat man auch gearbeitet, das war nach meiner Kenntnis eher ein akademisches Projekt und Himmler hat mal in kleinstem Kreis erwähnt, dass der erste Prototyp davon frühestens zwischen Juni und Oktober 1946 kommen könnte.

[p. 29] Besides, at the end of 1943, we were very modest at first; we [SS scientists] had begun with our own atom project, while Diebner, Ohnesorge, and the Austrians had started much earlier.

[p. 31] Even after the [Hitler] order, the program was not increased accordingly. This was not possible, because we, I mean Ohnesorge, Diebner and our [SS] groups, or rather little groups, had already worked out what resources were available and who would work with us. What now became easy was the coordination of the different systems. How the details were supposed to work, I cannot say, but there were three different directions:

First the uranium bomb, which was Ohnesorge's main passion and on which Diebner also worked.

Second the plutonium weapon, on which Ohnesorge had worked on the fundamentals, and which was also researched in Austria, along with other directions. Incidentally, the use of other materials besides plutonium was also investigated.

Third the hydrogen bomb. That was also worked on; to my knowledge, it was rather an academic project, and Himmler once mentioned in a small circle that the first prototype of this could come at the earliest between June and October 1946.

[Grothmann's comment that "the use of other materials besides plutonium was also investigated" for fission bombs likely refers to converting thorium-232, which was readily available from monazite ore, into uranium-233, another excellent fission fuel (pp. 3832–3839).]

[S. 7] Zu unserem Verbindungsbüro muß ich noch was sagen. Das sollte auch sicherstellen, daß bloß keine Doppelarbeit mehr gemacht würde. Das ist aber trotzdem so geblieben, weil ja die Reichspost ihre eigene Forschung weiterbetrieben hat, eigentlich bis zum Schluß. In den letzten Kriegsjahren, kann im Herbst 43 gewesen sein, ist aber zwischen Ohnesorge und Himmler eine enge Abstimmung beschlossen worden. Die Einzelheiten kenne ich bis heute nicht, Kammler war aber eingeweiht. Wenn also die Reichspost und natürlich die Diebner-Gruppen einbezogen sind, heißt das nicht, daß es viele Leute sein mußten. Für die spätere Serienproduktion sah es anders aus, aber dann hätten wir ja gegenüber den anderen Gruppen einen Vorsprung besessen und wir hätten auch Mittel gefunden, um den Geheimnisverrat zu begrenzen.

[p. 7] I have something to say about our liaison office. That should also make it clear that there would be no more duplication of effort. That remained the case, however, because the Reichspost continued its own research, right to the end. During the last years of the war, that may have been in autumn 1943, a close agreement was reached between Ohnesorge and Himmler. I still do not know the details, but Kammler was privy. So if the Reichspost and of course the Diebner groups are included, that does not mean that there had to be many people. It looked different for the later serial production, but then we would have had a lead over the other groups and we would also have found means to limit the betrayal of secrets.

[Grothmann described an extensive nuclear program that was spread over several autonomous organizations, which coordinated with each other and also with a central office run by the SS:

- Beginning no later than 1942, the SS provided coordination of all nuclear (and other research) activities through Heinrich Himmler and Hans Kammler, secretive funding for other organizations involved in the work, in-house R&D and production facilities, underground facilities, and massive amounts of slave labor.

- The Heereswaffenamt or Army Ordnance Office, with its own Army funding, had a scientific team led by Kurt Diebner and (except possibly during the final stages of the war) by Erich Schumann. It worked on implosion bomb designs and testing, fission chain reactions, gas centrifuges for uranium enrichment, and other aspects of the program. During 1939–1942, the Heereswaffenamt appears to have helped to coordinate the program with other organizations. After the overall coordination was assumed by the SS, Kurt Diebner seems to have continued to help manage the scientific details of the overall program.

- The Reichspost or Post Office, led by the physicist Wilhelm Ohnesorge, used its considerable direct income from postal payments to secretly fund its own nuclear laboratories and scientists, including Manfred von Ardenne, Fritz Houtermans, and Siegfried Flügge. The Reichspost began work no later than 1939 (p. 3375), and focused largely on enriching uranium for an implosion bomb, although it was also involved with other aspects of the overall program. No later than 1942, the Reichspost program became closely coupled to and partially funded by the SS, due to a close working relationship between Ohnesorge and Himmler (pp. 3378–3379).

- Austrians played a major role in the overall nuclear program, although Grothmann did not name or described them in detail. The most prominent Austrian nuclear physicists were the group led by Georg Stetter in Vienna. They began working on nuclear physics no later than 1928, and began seriously pursuing both fission and fusion devices no later than 1939 (pp. 3372–3375, 4330–4345, 4788–4800, 4992). There were a number of known or suspected nuclear-related sites in Austria (p. 3673). According to Grothmann, the Austrian scientists played critical roles in the development of both plutonium weapons and the hydrogen bomb.

- Czechs also played an important role in the overall nuclear program, yet Grothmann provided even less detail about that. There were many known or suspected nuclear-related sites in Czech territory (p. 3674).

- Grothmann mentioned a late-1944 nuclear bomb test that was conducted in Poland, indicating that there was also important nuclear work in Poland, but he did not give any details about work there. There were many known or suspected nuclear-related sites in Polish territory (p. 3674).

- Grothmann mentioned that only a few companies could provide what the nuclear program needed. Although he did not name the companies, they would likely include the major companies for uranium (especially Union Minière, Auer/Degussa, Buchler Braunschweig, and Treibacher Chemische Werke), the major chemical company (I. G. Farben, for chemical compounds involved in uranium enrichment or plutonium extraction), and the major companies for large electrical machinery (especially Siemens and AEG).

- Grothmann stated that Werner Heisenberg and Otto Hahn were not supportive of the nuclear weapons program and therefore were not involved in it. Their experiments were funded separately and at a relatively low level. The U.S. Alsos Mission and most books on the history of the German nuclear program have focused on that sideline and ignored the main program described by Grothmann and numerous documents in this appendix.

- It is possible that other important organizations were involved in aspects of the overall nuclear program yet not named by Grothmann; perhaps he either did not know much about their roles or else focused on other areas in his interviews. Among the most prominent organizations not named by Grothmann are the Kriegsmarine or Navy, the Luftwaffe or Air Force, and a group of scientists led by Paul Harteck in the Hamburg/Kiel area. More information is needed to clarify whether or how these organizations played roles in the overall nuclear program.

Grothmann's statements about the secrecy, organization, and achievements of the wartime German nuclear program are supported by many other documents presented in this appendix. As just one example, the next pages show several surviving documents that demonstrate that Wilhelm Ohnesorge and Heinrich Himmler began collaborating on various research projects no later than June 1942 and continued to do so thereafter, involving both Werner Grothmann and Hans Kammler in their communications about the projects, exactly as claimed in the transcripts of Grothmann's 2000–2002 interviews with Wolf Krotzky.

Of course, communications specifically regarding any nuclear weapons project would have been destroyed or never committed to writing in the first place, but these handful of surviving documents do demonstrate the general research collaboration between the Reichspost and the SS, as well as several of the key people who were involved.

I am not aware of any documents that contradict or disprove Grothmann's statements.

Thus while Krotzky's method of preserving Grothmann's testimony was unorthodox, relevant statements from Grothmann will be presented periodically throughout this appendix so that their details may be compared with those from other sources.]

D.3 Sources of Uranium and Thorium

[During the war, Germany had access to large amounts of natural uranium and thorium ore by (see map on p. 3405):

- Acquiring at least 1200 tons, and according to some well-informed sources 3500 tons, of uranium compounds (originally mined in the Belgian Congo) from Union Minière in Brussels [e.g., pp. 3335, 3408–3414].
- Expanding uranium mining at St. Joachimsthal (Jachymov), Bohemia [e.g., pp. 3418–3429, 3445, 3469–3470, 4978–4984; Hayes 2004, pp. 132–133, 235, 243].
- Mining uranium at Příbram/Przibram/Pibrans, Bohemia [e.g, pp. 3424, 3470, 3751–3754].
- Mining uranium at Schmiedeberg, Silesia [e.g., pp. 3328, 3424, 3429, 3445, 3471].
- Possibly using any of several uranium deposits in Thuringia [e.g., pp. 3468–3469; Zeman and Karlsch 2008].
- Mining uranium at Schneeberg, Saxony [e.g., pp. 3416, 3424, 3426–3428, 3433–3437, 3445, 3456, 3468–3469, 3708, 4922; Zeman and Karlsch 2008].
- Mining uranium at Johanngeorgenstadt, Saxony [e.g., pp. 3416, 3424, 3426–3428, 3433–3437, 3456, 3468–3469, 3708, 4922; Zeman and Karlsch 2008].
- Mining uranium at Freiberg, Saxony [e.g., pp. 3424, 3426–3429, 3445, 3468–3469].
- Mining uranium at Durrnaul near Marienbad [e.g., p. 3424].
- Mining or planning to mine uranium at Mladkov/Wichstadt, Bohemia [e.g., p. 3425].
- Operating and receiving shipments from Bulgarian uranium mines such as a mine at Buchovo (or Buhovo, a suburb of Sofia), since 1938 [e.g., Hayes 2004, p. 235; https://ejatlas.org/conflict/life-after-the-uranium-mines-in-buhovo-bulgaria]. See also pp. 3446, 3470, 4588.
- Mining uranium at Băiţa-Plai and other sites in Romania [e.g., pp. 3449–3455, 3471].
- Acquiring uranium from mines at Viseu and Guarda, Portugal [e.g., p. 3445; Hayes 2004, p. 235].
- Procuring all available monazite thorium ore in occupied Europe [e.g., Irving 1967].
- Exploiting other possible sources—Spain, Scandinavia, etc.?

One 1946 U.S. intelligence report on Czech uranium mines noted, “The Germans put mining on a high priority and only mining was done throughout the 6 years occupation. The ore was delivered by special planes to Germany and Austria” (p. 3998). Another 1946 U.S. intelligence report added: “The Germans continued operations in this mine to the very last moment” (p. 4981).

Thus Germany began actively mining uranium in 1938 and continued until the end of the war. During that time, Germany had access to (1) the same quality and a comparable quantity of Congolese uranium that served the Manhattan Project well, (2) Central/Eastern European uranium mines that later served the Soviet nuclear program well, and (3) additional uranium mines too.

Figure D.73: Sites of known uranium/thorium mining for the German nuclear program.

Germany processed uranium and thorium ore to uranium oxide and thorium oxide, and thence to uranium or thorium metal or to a variety of useful chemical compounds—uranium hexafluoride, uranium tetrachloride, uranium nitrate, etc.—at numerous locations including (see map on p. 3407):

- Union Minière in Brussels [e.g., pp. 3335, 3408–3414; Irving 1967, p. 65].
- Auer in Oranienburg, Katowice/Kattowitz, and other locations [e.g., pp. 3446, 3458, 3461–3463, 3465, 4980; Nagel 2016].
- Buchler in Braunschweig [e.g., pp. 3420, 3430–3431, 3458, 3460–3463, 3465, 4980].
- Treibacher Chemische Werke in Althofen, Austria [e.g., pp. 3420, 3432–3437, 3458, 3460, 4980; Gollmann 1994].
- Degussa in Frankfurt, Berlin, Stadtilm, and possibly other locations [e.g., pp. 3458, 3461–3465; Hayes 2004; Nagel 2016].
- Chemische Fabrik Grünau in Berlin [e.g., pp. 3438–3439, 3461–3463].
- I.G. Farben in Leverkusen and other locations [e.g., pp. 3488–3489, 3492–3493, 3678–3680, 3748–3750, 4440–4477; Mader 1965, pp. 193–202, 229-233].
- Krupp in Essen [e.g., pp. 3458, 3461–3463, 3465–3467].
- W. de Boer in Hamburg and Wittingen [e.g., pp. 3458, 3461–3463, 3465].
- Radium-Chemie AG in Frankfurt [e.g., pp. 3440–3441, 3458, 3465].
- W. Maier KG Radiumchemische Industrie und Laboratorium in Villingen-Schwenningen am Neckar and other locations [e.g., Oleynikov 2000].
- Příbram/Przibram/Pibrans, Bohemia [e.g., pp. 3423, 3751–3754].
- Facilities in Dresden [e.g., pp. 3423, 3426].
- Reichswerke Hermann Göring in Linz and other locations [e.g., pp. 3877–3880].
- Possibly other facilities.

At the end of the war, Allied countries removed over 2800 tons of uranium and thorium compounds from former German-controlled territory (p. 3456). In addition, in 1974, Alwin Urff, deputy technical plant manager of the Asse nuclear disposal site in Germany, stated: "When we began storage in 1967, our company first sank radioactive waste from the last war, that uranium waste which arose in the preparation of the German atomic bomb" (p. 3472).]

[While uranium ores found at various sites in Europe were good (and later proved sufficient for the large postwar Soviet nuclear weapons program), the ore with the highest natural concentration of uranium was found in Congo, which was controlled by Belgium at that time [Susan Williams 2016].

Just exactly how much Congolese ore did the whole German nuclear program manage to acquire, via Belgium or any other means?

Most sources give a total number of 1200 tons or so (see for example p. 3335).

However, at least two sources say that the actual amount was 3500 tons:]

1. Nikolaus Riehl, the head nuclear chemist at Auergesellschaft, in information that he gave to David Irving [Irving 1967, pp. 65, 90–91].

The Ministry of Economic Warfare, whose department it was, was requested to attempt to deprive the Germans of the stockpiles of uranium-oxide in Belgium; Tizard opposed the outright purchase of the thousands of tons of uranium-oxide there, and proposed that it should merely be moved to the United Kingdom. The Ministry acted with ponderous precision, and when the German armies fell upon Belgium a month later by far the greater part of the uranium was still there.

Up to June 1940, Union Minière had sold no more than about a ton of the various compounds to Germany each month; the company now received an immediate order for sixty tons of refined uranium compounds, to be supplied to the Auer company in Berlin. During the next five years, the Germans seized three thousand five hundred tons of uranium compounds from the Belgium stockpiles, and shipped it under the general supervision of Dr. Egon Ihwe[6] back to Central Germany, where it was stacked in the surface buildings of the old salt-mines at Stassfurt, owned by the Industrial Research Association (*WiFo*). It was from this huge stockpile of sodium- and ammonium-uranate that the Auer company would now meet its requirements. [...]

[T]he committee stressed: '[...] Although steps were taken beforehand to induce the Belgian company to reduce stocks of uranium oxide, some of which are now in Canada, some eight tons[7] are believed to have fallen into the hands of the Germans when Belgium was invaded.'

---

[6] General Manager of Auer's subsidiary, the Oranienburg Rare Earths Factory; and an agent of the *Reichsstelle Chemie*, the Reich Chemicals Authority.

[7] Margaret Gowing, *Britain and Atomic Energy 1939–1945*, quoting the committee's report, drew attention to this error and said that it was discovered that the Germans had acquired the equivalent of 600 tons of uranium-oxide; but Professor N. Riehl has informed the author that it was in fact very much more.

2. William Casey, who was a senior official in the OSS and later head of the CIA, and thus should have been in a position to know the correct answer, along with his staff archivists and analysts [Casey 1988, p. 49].

When the British government learned that the Germans, on occupying Norway and Belgium, were increasing Norwegian heavy water production and had seized 3500 tons of uranium from Union Minière in Belgium, the Ministry of Supply was directed to study what would happen if an atom bomb was detonated in the center of a large British city.

[Dust jacket back flap:] WILLIAM CASEY was Chief of the London OSS headquarters during World War II, and Chief of Secret Intelligence for General Dwight D. Eisenhower's European operations. He was awarded the Bronze Star. In 1981 Mr. Casey became director of the CIA. He died May 6, 1987.

[During the war, the United States had a comparable amount of the same Congolese ore (~1100 metric tons from a warehouse in New York, with more arriving later in the war) and managed most of the Manhattan Project with that stock. See for example:

https://www.osti.gov/includes/opennet/includes/MED_scans/Book%20VII%20-%20%20Volume%201%20-%20Feed%20Materials%20and%20Special%20Procuremen.pdf

https://www.governmentattic.org/5docs/TheNewWorld1939-1946.pdf

The Germans could potentially have done just as well with what they had.]

ALSOS Mission

16 September 1944

SUBJECT: Union Miniere du Haut Katanga, Preliminary Study of Data.

[illegible]

Crude Ore:

All of it was evacuated with the intention of shipping to England or U. S. A. At time of occupation--

500 tons in Le Havre
630 tons in Ostend
1310 680 tons in Bruges
(251 tons evacuated to U. S. A. in 1939)
in addition to above

Havre Stock:

About 70 tons were sent on to Bordeaux, but never heard of again.

490 About 380 tons were taken to Germany in June 1940.

About 40 tons, meant for Germany, accidentally arrived at the Hoboken factory of U. M. du H. K. as the result of a German error.
Was refined and sent to England, 26.6 tons as refined.

Ostend and Bruges Stock:

After the occupation these were transferred to the Oolen factory.
1278 In June 1941 there were 1236 tons at Oolen and 42 tons at Hoboken.
Some sent to Brussels for refined; used for current orders

Taken to Germany:

In June 1942, 610 tons, all the crude ore that remained was taken to Germany from Belgium. In total--

380 tons from Le Havre (June 1940) Recovered at Stassfurt
610 tons from Oolen (June 1942)
70 tons from Bordeaux (?) 30 tons found shipped via Marseilles to U.S.

The latter quantity is of course uncertain.

Sent to Refinery at Brussels:

137 tons in 1939 (not evacuated)
150 tons in 1940 (from Hoboken and Ostend)
335 tons in 1941 (From Oolen)
325 tons in 1942 (from Oolen and Hoboken)

Union Miniere du Haut Katanga - cont'd. 15 Sept. 1944

except [illegible] unrefined

No crude ores remained in the possession of the U. M. du H. K.

The Germans paid prewar prices for all the material, except the booty found in France. *

(ca 10 + 13% water)

(Note that this ore is a "wet" product and that thus the amounts need not add up to the original value. Quantities are in round numbers in metric tons of 2200 pounds).

Rejects: (Impure)

All stocks were taken to Germany in June 1942, with the exception of 25 tons of "uranium residues" which were sent to Brussels for refining in 1941 up to June 1942.

Removed to Germany:

Ferro-uranium	17 tons	(40% U-metal) – Tungsten or Molybden substitute
Residues	53 tons	(30% U_3O_8)
Uranyl carbonate	44 tons	(40% U_3O_8)
Black Oxyde	4 tons	(90% U_3O_8)
Sodium Uranate	8 tons	(70% U_3O_8)

Finished Products:

On 8 September 1944 the data indicated that there remained in Belgium about 45 tons of ammonium urate, 2.5 tons of black oxide and about 10 tons of other products. Part of this was ready for shipment but probably has not been removed yet. *

This, at present, seems to be all that is left in Belgium. However, a further detailed check must be made as soon as the factory at Oolen becomes available.

Details of movements of refined products as well as precise data on crude ore are given on the data sheets prepared by the U. M. du H. K.

Summary:

Indicating only the principal movements we find--

Summer 1940 - 11 tons oxyde to Auer 380 tons crude to ?
Fall 1940 - 44 tons oxyde to Auer 70 tons crude lost ?
1941 - no large movements
Summer 1942 - 120 tons finished pr. to Roges
610 tons crude to Roges
125 tons rejects to Roges
Summer 1943 - 50 tons finished pr. to Roges
Winter 1943 - 40 tons finished pr. to Roges

EUROPEAN THEATER OF OPERATIONS
UNITED STATES ARMY
ALSOS Mission

15 September 1944

SUBJECT: German Recepients of Uranium Products from Belgium.

Several firms received small amounts apparently for normal peace time applications or retrade. The quantities being usually less than one ton of assorted refined material per month.

From June 1940 until August 1941 the Auer Gesellschaft, who never was a customer before the war, suddenly became a large consumer, a total of roughly 60 tons of refined materials over this period. The last two shipments to this firm were in July and August 1941 and were ten tons each.

The engineer at Auer Gesellschaft who was apparently in charge of uranium ore purchases was Dr. Ihwe. He visited Belgium in October 1940.

The next large shipment was in November 1941 of about nine tons to the Deutsche Gold und Silber Scheide Anstalt, who was a prewar customer for amounts of about two tons. This shipment may therefore have no special significance.

Suddenly in June 1942 unusually large amounts were requisitioned and sent to Roges, m.b.H., namely about 115 tons of assorted refined and half refined materials. In addition, they obtained 610 tons of crude material, 17 tons of ferro-uranium and about 110 tons of impure products designated as "produits non-marchands" that is "rejects". Also in Jan 43, 50 tons and in May 80 tons of refined products.

17
110
50
80

Roges m.b.H. is a war created trading office most likely directly connected with the German ministry of trade and Finance (Handels und Finanzministerium). Its full name is Rohstoff Handels Gesellschaft m.b.H (-Raw materials trade company Ltd.) and probably supervised the trade of all metallic ores.

The man in charge of uranium ores was Dr. Faust

The company was bombed out at least twice and requested new copies of their records from Belgium. An old address was:

Tirpitz Ufer 2024, Berlin W9

the latest address is probably:

Chaussee Strasse 6 - 10
Berlin - Mariendorf

SUMMARY OF MATERIALS SEIZED
AT S.

Probably of Belgian Origin:-		Metric Tons
Crude Sodium Uranate (Some of this may turn out to be refined products)	2834 barrels @ ~ 300 kgs net	850.5
	2800 bags @ ~ 75 kilos net (to be repacked in about 4000 barrels)	210
Ferro-uranium	70 barrels @ ~ 250 kgs net	17.5
	2 " @ ~ 50 " "	.1
Uranium nitrate	143 barrels @ ~ 50 " "	7.15
	TOTAL	1085.25

Probably of Czechoslovakian Origin:-	Metric Tons
10 boxes refined sodium uranate @ ~ 40 kgs.	.4
48 barrels containing unidentified material @ ~ 75 kgs.	3.6
13 drums containing unidentified material @ ~ 30 kgs.	.39
TOTAL	4.39

NOTE: All above figures are approximately only.

Chemical analysis carried out on one spot sample of crude sodium uranate gives a value for the U-content of 43%.

Figure D.79: Summary of Materials Seized at S[tassfurt]. [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL]

Jonathan E. Helmreich. 1986. *Gathering Rare Ores: The Diplomacy of Uranium Acquisition, 1943–1954.* Princeton, New Jersey: Princeton University Press. p. 70.

The CDT [Combined Development Trust, run by Leslie Groves] was aware of the uranium at Joachimstal and apparently did not think the Russians would be able to mine there extensively enough to gain the needed amounts of oxide. Despite the survey efforts of the UMDC and the Murray Hill area, however, the CDT did not know of the valuable deposits in Saxony, just north of the East German border with Czechoslovakia and the Joachimstal mines. Discovered by the Germans in 1943, the deposits were explored by the Soviets in the months after June 1945; mining operations began a year later and were feverishly expanded after April 1948.

[The Saxony/Erzgebirge uranium deposits were enormous, and the Soviet Union mined them for decades after the war to supply uranium for its nuclear weapons program.

Germany began exploiting those deposits during the war (see also for example pp. 3433, 3456–3416, 3708, 4922), so it had access to even more uranium ore than it is already publicly known to have possessed.]

Zbynek Zeman and Rainer Karlsch. 2008. *Uranium Matters: Central European Uranium in International Politics 1900-1960.* Budapest: Central European University Press. pp. 25–29, 24.

The Soviets were initially more interested in tracing the German atomic program and recruiting German scientists than in the search for uranium. Despite strong opposition from the Communist Party bureaucracy, Zaveniagin sent a group of forty Soviet physicists to Germany. They succeeded in convincing eminent German scientists, including Manfred von Ardenne, Gustav Hertz, Heinz Pose, Nikolaus Riehl, Peter Adolf Thiessen and Max Volmer, to work for the Soviet atomic program.

As early as 15 May 1945, NKVD presented in Moscow the results of their investigations into the German plants and research institutes which concerned themselves with nuclear matters. Among the institutions visited were the Kaiser-Wilhelm-Institut für Physik in Berlin-Dahlem, Manfred von Ardenne's institute in Berlin-Lichterfelde, Institut der Reichspostforschungsanstalt in Zeuthen (Miersdorf), the Siemens cyclotron laboratory run by Gustav Hertz, as well as the plants and warehouses of the Auer company in Berlin-Charlottenburg, Berlin-Grunau, Oranienburg and Zechlin.

The objects came under NKVD control and were soon dismantled. Special units found about 300 tons of uranium oxide and 7 tons of uranium metal in Berlin, Gottow, Zechlin, Kagar, and Rheinsberg. In Stadtilm, a small town in Thuringia, the special unit found a uranium processing plant that used to belong to the Degussa Company. The Auer Company's plant in Oranienburg, destroyed in the American air raid in March 1945, was also thoroughly searched; a few tons of pure uranium oxide and several hundred tons of thorium derivatives were found there.

[...] The first group came to Bulgaria at the end of November 1944. It followed a German trace: Soviet troops had discovered some German documents concerning uranium reserves in the vicinity of the town of Buchovo. [...] Political prisoners were employed in the uranium mines and, by the middle of 1946, the company had produced 272 tons of pitchblende, which was then sent to the Soviet Union.

[...] Beria's special committee for the atomic bomb received the first report on Jáchymov [Sankt Joachimsthal, Bohemia until 1945, then Czechoslovakia] on 14 September 1945. The estimated uranium reserves in Jáchymov amounted to 300 tons.

[...] Early in August 1945, an expedition of Soviet geologists, led by Professor Kreiter, came to Saxony. The geologists visited the headquarters of the Sachsenerz-Bergwerks AG in Freiberg and the mines near Schneeberg and Johanngeorgenstadt. [...] the estimates reached the figure of 1,600 tons.

[...] by the time mining was concluded there after 1989, it would produce over 231,000 tons of uranium.

IN RE: The Czech Mines

1) We know that the normal uranium extraction at the old Czech mines in Joachimstahl (Jacymov) is insufficient for our present purpose. If metal is to be obtained from this source, a considerable expansion of the works is necessary. Our airplane dial analysis and your information indicate that sizable quantities of radium are not required for dial paint. It is possible that therapeutic needs and especially gamma-ray radiography of heavy metal parts require a large increase in the radium output, but it seems probable that any large scale activity at Joachimstahl is of real significance.

2) It must be recognized that the literature increasingly hints at an intensive activity at Joachimstahl. This information is derived from the publications and reports of the group working under B. Rajewsky at the KWI für Biophysik at Frankfort a. M. We early reported his references to seeking new radium veins and to continued work on the health hazards presented by uranium ore dusts. The latest publication to come to our attention (dated November 1943, written several months earlier) gives a report of the general activities of this section of the KWI for the year ending March 1943. In this report is emphasized the war-important character of the work of this Institute, particularly that carried out at the subsidiary site of the Institute, the so-called Radiumforschungsinstitut, located at the small town of Radiumbad Oberschlema in the Erzgebirge. It is quite clear that these people have been given a governmental responsibility to safeguard the health of the radium workers at Joachimstahl and perhaps at other nearby newer radium mines.

8-12-1.2 4 8-12-2.3

3) We very strongly recommend that you obtain as definite a report as possible on all the activities connected with radium mining and extraction in the Erzgebirge of Czechoslovakia. You will recognize the connection between this work and many of the reports which you have lately obtained. The scale of any possible uranium ore removal for radium extraction purposes is considerably less than the scale for more important purposes. This might possibly take an almost decisive character for us.

4) The scientific workers involved in the work of the KWI für Biophysik are listed below; the most important of them is B. Rajewsky. The list follows:

B. Rajewsky
M. Dorneich
W. Drublow
G. Kahlau

A. Krebs
H. Schaefer
A. and E. Schraub

SECRET

Not only the circles of physicists will know these people, but perhaps even more the radiologists or research workers in the field of X-ray and radium cancer therapy.

SUMMARY OF INFORMATION

Received between
1 May and 31 May 1944

The possibility of a German project of more than pilot plant size grew less and less remote during the last month. The Czech mines at Joachimstahl and Schoenficht which were photographed showed little increased activity since the war. Heavy water production at Rjukan has stopped completely. Research work in Bohr's laboratory in Copenhagen is reported at a standstill. Von Weizsacker, who was reported in charge of the laboratory, has returned to Strassbourg. Dresden, often reported as a seat of secret weapon activities and associated with the name of Heisenberg and heavy water, has been found to be the center of the crossbow activity. There is evidence that hydrogen peroxide, the propellant for rockets, is the subject of research at Dresden. Thus, rumors that Dresden is connected with this project seem unlikely unless the work in Dresden is of a minor nature. More evidence has been discovered connecting the Reichspost with nuclear research. It has been reported that certain German patent rights have been applied for in connection with thermal diffusion equipment.

TOP SECRET

Washington, D.C.
25th April, 1946.

Number: 117

Dear Eric,

I have just been reading through two most interesting letters received from Dean dated 17th and 18th of April on the subject of JOACHIMSTAL. I must say, however, that I am somewhat amazed at some of the statements.

In particular I cannot understand why you consider the SSU Report L.C.545 - "the best single report to emerge....." etc.

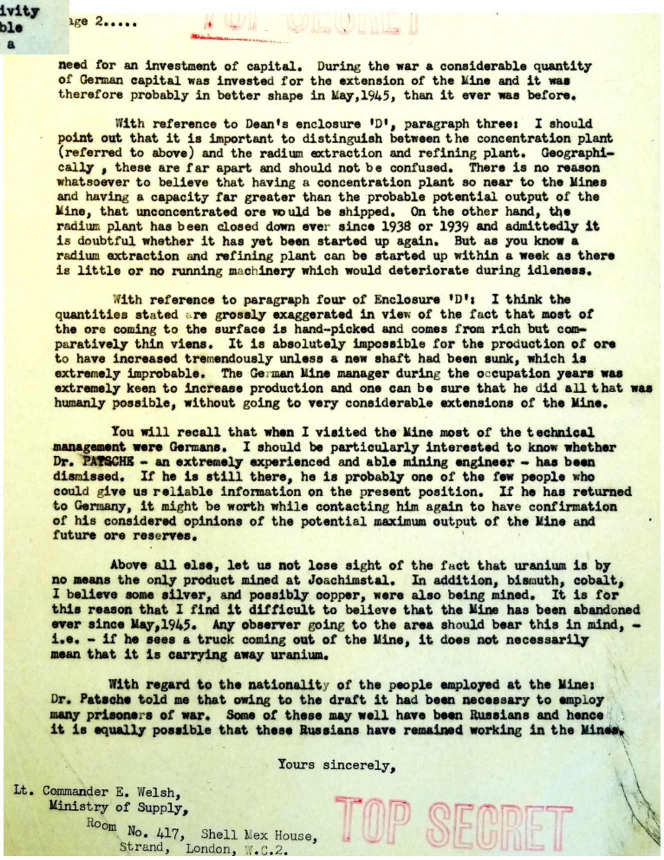
I agree of course, with paragraphs one and two of this report, but paragraphs three and four appear to me to be complete nonsense to anybody who knows the facts.

When I visited the Mines in May, 1945, the machinery was going at full blast and everything was in good working order. It is, of course, possible that subsequent to my visit, the Mines may have been closed down for a short time, but it is inconceivable to believe that the machinery would have been left in a state in which it could deteriorate during a few months.

The production during the war years averaged about the equivalent of twelve tons per annum, or less, of uranium-oxide. All the ore is concentrated to 60 - 70 per cent U.308 at the concentration plant which is located at the entrance to the Edleutstollen Mine. It does not need a great mathematician to work out that not more than two trucks per annum would be needed to remove all the concentrates produced. I simply cannot understand, therefore, the emphasis in so many reports on the large number of box cars which will be necessary to remove the ore. Furthermore, most of the ore is hand-picked to a high concentration before being brought to the surface. It is brought to the concentration plant in bogies. Since most of the traverse from the Mine shaft to the refinery is underground, the bogies themselves are only visible over a stretch of about 10 metres.

In short, the Mine can be working at full blast but unless one can get into the factory area itself - (which is only about 300 yards by 300 yards) - one would never see any signs of activity. The only external observation which would be of any use would be to know the number of work people going to the Mine per day. Since there is only one road access to the factory area, it should not be difficult for a casual observer to count the number of employees reporting for work.

With regard to paragraph four: I can conceive of no unusual activity which would be necessary to rehabilitate the Mine which would be noticeable to an outside observer, and I can think of no reason why there should be a



ge 2.....

need for an investment of capital. During the war a considerable quantity of German capital was invested for the extension of the Mine and it was therefore probably in better shape in May,1945, than it ever was before.

With reference to Dean's enclosure 'D', paragraph three: I should point out that it is important to distinguish between the concentration plant (referred to above) and the radium extraction and refining plant. Geographically, these are far apart and should not be confused. There is no reason whatsoever to believe that having a concentration plant so near to the Mines and having a capacity far greater than the probable potential output of the Mine, that unconcentrated ore would be shipped. On the other hand, the radium plant has been closed down ever since 1938 or 1939 and admittedly it is doubtful whether it has yet been started up again. But as you know a radium extraction and refining plant can be started up within a week as there is little or no running machinery which would deteriorate during idleness.

With reference to paragraph four of Enclosure 'D': I think the quantities stated are grossly exaggerated in view of the fact that most of the ore coming to the surface is hand-picked and comes from rich but comparatively thin viens. It is absolutely impossible for the production of ore to have increased tremendously unless a new shaft had been sunk, which is extremely improbable. The German Mine manager during the occupation years was extremely keen to increase production and one can be sure that he did all that was humanly possible, without going to very considerable extensions of the Mine.

You will recall that when I visited the Mine most of the technical management were Germans. I should be particularly interested to know whether Dr. PATSCHE - an extremely experienced and able mining engineer - has been dismissed. If he is still there, he is probably one of the few people who could give us reliable information on the present position. If he has returned to Germany, it might be worth while contacting him again to have confirmation of his considered opinions of the potential maximum output of the Mine and future ore reserves.

Above all else, let us not lose sight of the fact that uranium is by no means the only product mined at Joachimstal. In addition, bismuth, cobalt, I believe some silver, and possibly copper, were also being mined. It is for this reason that I find it difficult to believe that the Mine has been abandoned ever since May,1945. Any observer going to the area should bear this in mind, - i.e. - if he sees a truck coming out of the Mine, it does not necessarily mean that it is carrying away uranium.

With regard to the nationality of the people employed at the Mine: Dr. Patsche told me that owing to the draft it had been necessary to employ many prisoners of war. Some of these may well have been Russians and hence it is equally possible that these Russians have remained working in the Mines.

Yours sincerely,

Lt. Commander E. Welsh,
Ministry of Supply,
Room No. 417, Shell Mex House,
Strand, London, W.C.2.

~~DRAFT~~

~~HSL/ls~~
~~3 May 1946~~

TOP SECRET

~~SUMMARY ANALYSIS OF JOACHIMSTHAL INFORMATION RECEIVED~~
~~UP TO 1 MAY 1946~~

I Precis of all pertinent reports follow. Those having underlined headings are considered valid reports. Those ~~receipted~~ preceded by asterisks are considered invalid reports. Those without any mark are newspaper and radio reports from Czechoslovakia or Russia.

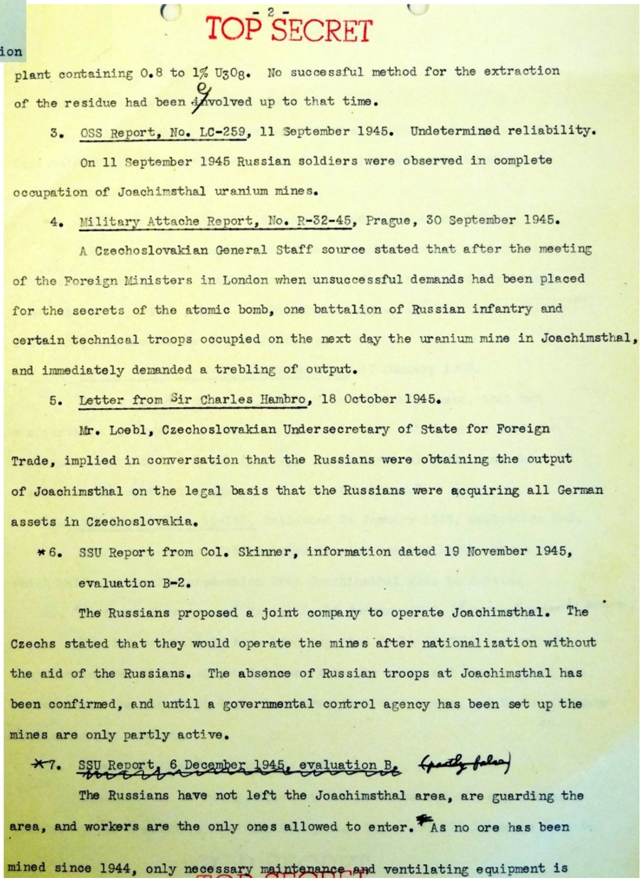
1. Interrogation of P/W Uffz, 31G-1520041, 28 December 1944.

In April 1939 Joachimsthal came under control of the German Government. The radium refining plant in the center of town was discontinued, the working force reduced from 250 to 180 workers in the mine, and 15 men were left in the office. Plant output remained at 10 tons U_3O_8 per year. About 1/3 of the output was delivered to the Chinin Fabrik in Braunschweig and the other 2/3 to the Chemischewerke in Treibach, Austria. Simultaneously laboratory control was eliminated with the exception of medical control tests.

2. Letter from Gattiker and Davis to Groves, 15 May 1945. Visit to Joachimsthal Mines.

There are three mine shafts spaced at one mile intervals lying approximately in a straight line, ~~each pair about a mile apart~~. From west to east are: (a) the Wernerschact with 4 veins being worked, (b) the Einigkeitschact in the center of the town, no longer worked, and (c) the Edelleutstollen, with 3 veins being worked. The Germans concentrated the mined ore to 12% by hand picking underground, and then concentrated it to 60% U_3O_8 in the concentration plant near the Edelleutstollen shaft by crushing followed by tabl~~e~~ing. The concentration plant has a capacity of 10 tons of crude ore per day.

Stocks on 15 May 1945 were given as 3 tons of 60% concentrate, 20 tons of 11% crude ore concentrate, and 3,000 tons of residue in the concentration



- 2 -

TOP SECRET

plant containing 0.8 to 1% U_3O_8. No successful method for the extraction of the residue had been ~~i~~evolved up to that time.

3. OSS Report, No. LC-259, 11 September 1945. Undetermined reliability.

On 11 September 1945 Russian soldiers were observed in complete occupation of Joachimsthal uranium mines.

4. Military Attache Report, No. R-32-45, Prague, 30 September 1945.

A Czechoslovakian General Staff source stated that after the meeting of the Foreign Ministers in London when unsuccessful demands had been placed for the secrets of the atomic bomb, one battalion of Russian infantry and certain technical troops occupied on the next day the uranium mine in Joachimsthal, and immediately demanded a trebling of output.

5. Letter from Sir Charles Hambro, 18 October 1945.

Mr. Loebl, Czechoslovakian Undersecretary of State for Foreign Trade, implied in conversation that the Russians were obtaining the output of Joachimsthal on the legal basis that the Russians were acquiring all German assets in Czechoslovakia.

*6. SSU Report from Col. Skinner, information dated 19 November 1945, evaluation B-2.

The Russians proposed a joint company to operate Joachimsthal. The Czechs stated that they would operate the mines after nationalization without the aid of the Russians. The absence of Russian troops at Joachimsthal has been confirmed, and until a governmental control agency has been set up the mines are only partly active.

*7. ~~SSU Report, 6 December 1945, evaluation B.~~ (partly false)

The Russians have not left the Joachimsthal area, are guarding the area, and workers are the only ones allowed to enter. *As no ore has been mined since 1944, only necessary maintenance and ventilating equipment is

MEMORANDUM FOR THE FILES

Subject: Salient Facts on Joachimsthal.

Vital Statistics

1. Potential Reserves. According to Dr. George Bain, the potential reserve of Joachimsthal including subsurface deposits and tailings stored above ground is 390 tons of pure uranium oxide (U_3O_8).

2. Ratio of Uranium Oxide to Rock. The run-of-the-mine material at Joachimsthal is as follows:

According to Bain	According to Davidson
99.7% Rock	99.2% Rock
00.3% Uranium Oxide	.8% Uranium Oxide

3. Production during World War II. During the War years, production of pure uranium oxide is estimated as follows:

1939-40	5.75 metric tons
1940-41	7. " "
1941-42	8. " "
1942-43	12. " "
1943-44	12. " "

Taking peak production of 12 tons per year of pure uranium oxide and using the figures quoted in paragraph 2, this would mean:

According to Bain		According to Davidson
4,000 metric tons	Run-of-the-mine-rock brought to the surface per annum	1,500 metric tons

Per day this would mean:

According to Bain		According to Davidson
13 metric tons	Run-of-mine-rock brought to the surface per day	5 metric tons

TOP SECRET

Mines and Miners

4. There are three uranium or pitchblende mining areas in Joachimsthal: the West Mine, East Mine, and Far East Mine generally called the Edellentstollen Mine.

5. West Mine is one mile (1.7 km) west of the center of Joachimsthal. It is entered by the Wernerschacht (Werner Shaft).

6. East Mine is in the center of town. It is entered by the Josephschacht (Joseph Shaft) in the center of town; also by the Einigkeitschacht (Concord Shaft) 300 ft. (100 m) to the West. This mine has been worked longer and deeper than the others. It has been out of action for many years due to flooding. Its only use at present is to supply radon emanations for the radium baths.

7. The Far East or Edellentstollen Mine is 1½ miles (2.4 km) east of the center of Joachimsthal.

8. Working Faces. Dr. Bain thinks there may be 6 working faces at the present time.

9. Number of Miners Employed. The "basic unit" underground is: 2 miners who actually drill and cut away the rock, and 1 mucker who loads the broken rock into one-ton mine cars. The basic unit of 3 men can get 7 - 10 tons of rock per day to the principal underground haulage point. In addition to the 3 men, an additional 3 are needed to do track laying, pipe fitting, timber setting, etc.

Processing

10. The purpose of processing is to separate the valuable pitchblende (the valuable element because of its radium and uranium content) from the worthless rock. There may be no processing going on at Joachimsthal. Or it may be going on in one or all of the following phases:

11. Pulverizing. This entails a good-size building probably 40 feet (12 meters) high. This building was in use throughout World War II and was left intact by the retreating Germans. Its capacity is 10 tons of crude ore per day. The run-of-the-mine or even the selected ore is pulverized in successive steps.

a. A jaw crusher will yield pieces of rock 2 inches (5 cm) in diameter.

b. As the 2 inch pieces move along a belt, there may or may not be men taking off high-grade chunks of pitchblende. In any event,

c. Rollers will further pulverize the material to tiny nuggets 1/8 inch (3 mm) in size.

d. There is a last stage of crushing from which the material emerges in granular form. Each grain will be 1/100 inch (1/4 mm) in diameter. This is slightly finer than finest beach sand. The material at this stage in color and general appearance will resemble beach sand.

TOP SECRET

12. Separating. This will take place in a different building or shed. The purpose now is to separate grains of pitchblende from the worthless grains of rock. This can be done by: shaking tables and jigs.

13. Chemical Plant. The uranium refinery was working until 1939. (The radium refinery was closed in 1935 as a result of cheaper radium production in Belgium and Canada. It is probably still closed.)

Scrap or Tailings

14. Scrap or Tailings. In former years, the pitchblende mined at Joachimsthal was processed almost solely for its radium content. Radium processing ended in 1935 because of lower-priced radium coming from Belgium and Canada. Both radium and uranium can be obtained from the pitchblende. But in earlier years there was no appreciable commercial use for uranium. Hence the granular residue, once the radium was extracted, was dumped on a scrap pile. The scrap is also called "tailings".

15. The scrap or tailings are likely to be stored in the open air and in depression areas. It will resemble light colored beach sand, and will be finer than the finest beach sand. Its uranium oxide content is 1/4 - 1/3 of 1%. There may be 30,000 tons of tailings in the area. (This would yield about 90 tons of pure uranium oxide.

Characteristics of Pitchblende and Uranium Oxide

16. There are several characteristics of pitchblende and uranium oxide:

a. Weight. The outstanding characteristic is their heavy weight. This however, must be carefully defined:

(1) Let us assume no selection is done underground. The run-of-the-mine material which is brought to the surface will have a normal weight. For the run-of-the-mine material is only 00.3% pitchblende and 99.7% rock.

(2) Let us assume some selection is done above ground, much worthless rock is thrown away, so that the resulting mass is 10% pitchblende and 90% rock. This mass will be 1/2 again heavier than the comparable mass of run-of-the-mine material.

(3) Let us assume the selection is more intense so that the resulting mass is 60% pitchblende and 40% rock. This mass will be 3 times heavier than the comparable mass of ordinary rock or run-of-the-mine material.

b. Color. Pitchblende is black. The run-of-the-mine material is gray or white. Pitchblende is usually dull, but sometimes it may be shiny.

c. Shape. Pitchblende will break into irregular lumps. The worthless rock will break into flat, irregular shaped slabs or sheets.

TOP SECRET

Physical Appearance When Shipped

17. Whether shipped by rail or truck, the following characteristics will prevail:

a. If no processing takes place locally, the product shipped will be run-of-the-mine material. It will be loaded loose (not boxed or packaged). The rock as loaded will be gray or white in color; the shape will be flat, irregular-shaped slabs or sheets. Ten tons will in bulk as well as weight fill a 10-ton rail car.

b. Let us assume they are shipping a mixture of 90% rock and 10% pitchblende, as described in paragraph 16a (2). This will be loaded on rail cars or motor trucks loose (not boxed or packaged). The color will be dark gray with splotches of black, as if pieces of coal were mixed with it. Because of the high specific gravity of the now concentrated rock, a 10-ton rail car when loaded with its full 10 tons will appear only 60% full. In other words, if coal cars are used they will appear about half full.

c. Let us assume Joachimsthal is shipping a greatly enriched mixture of 40% rock and 60% pitchblende, as described in paragraph 16a (3). This will be in granular form. It will be packaged and will be very heavy.

(1) If it is shipped in bags or sacks, each bag will be half the size and twice the weight of a bag of Portland cement.

(2) It may be shipped in wood or steel drums. The drums must be very small (because of the great weight) to be lifted by laborers. If the drums are large, special equipment will be needed for lifting and hauling.

d. If the long-stored scrap or tailings are shipped by rail or truck, the following will be true. The granular tailings or "sand" will be shipped loose. The color will be a dirty yellow or gray. The granular tailings will be heavy and a rail car or truck will be but partially filled when loaded to capacity.

Other Intelligence Signs

18. Look for dirty wooden boxes of these unusual dimensions: 5 feet long, 1 foot wide, 2 inches high. Such boxes are used in transporting drill bores. A diamond drill in operation will loom up at least 12 feet above the surface of the ground. A typical sign when a drill is in operation: the surface of the ground will be covered with dirty oil for a great area around.

19. People resident in old mining towns are apt to talk about the extensive workings beneath the town. The accounts may be exaggerated but they are frequently indicative of the extent, limits and trend of the deposits. Should the conversation develop along such lines it would be good to express doubt whether the work went that far, or thirty feet less, or make some such innocuous statement to learn where present activity is located: (a) at the north side or south side (b) on the Schweizer, Hillebrand, Franz Joseph or other veins (c) in the west, east or Edellent mines (d) cleaning out old workings or in new development (e) extension of old galleries or opening new levels below 540 meters.

TOP SECRET

20. The really high grade and wide vein was the old Schweizer (Swiss) vein. There is a strong tendency of miners to recall the glory that the mine had and to compare each new rich pocket with the great bonanza. Any loose talk on rich pockets might be made good working capital by recalling the Schweizer vein on the upper levels and suggesting that the new one couldn't be half as good as that place had been.

Cables on Jachymov Mines "Evaluation A2. On 13 August General Svoboda and Bocek Czech Minister of National Defense and Chief of Staff visited mines after 3 day conference in Praha attended by over 200 Reds. Soviet engineers have reported that deposits are sufficient to meet Russian demands and plans have been drafted for employ of 4,500 expert miners from Pribram. Soviet has promised them increased foodstuffs and luxuries. Russian mineralogists (living at Hotels Pupp and Imperial in Karlovy vary) claim discoveries of new and richer deposits in Jachymov Area which will be exploited only by Russians. Czechs request to have concentration plant on Czech soil denied by Russians. All ore will go to Dresden as heretofore."

Have requested additional information on new richer Jachymov discoveries of deposits claimed by Russian mineralogists.

STANDARD FORM NO. 64

Office Memorandum • UNITED STATES GOVERNMENT

TO :

DATE: 24 Sept. 1946

FROM :

SUBJECT: Uranium in the Erzgebirge (Czach)

1. Dr. Bain let me see a draft of a proposed report on the Erzgebirge Area. I extracted the following as useful information.

2. Schneeberg:
Production between ~~Schneeberg and Neustadtel~~ 1870-1907 was 80 metric tons. The mines are situated in a 10 km.^{2} area between Schneeberg and Neustadtel. At least this area is said to be mineralizd.

3. Johanngeorgenstadt:
Mineralization not so strong as at Schneeberg. Veins have produced considerable bismuth as well as silver and cobalt. Strongest uranite vein is in the Vereinigt Mine in the Fastenberg. Maximum yield was 2.7 tons in 1905.

4. Durrnaul near Marienbad:
Said to have a shoot with 100 tons of U_3O_8 in an ore lens. Principal occurrences are in the St. Viti mine.

5. Freiberg:
Said to account for one twelvth of the Saxony production of uranium.

6. Schmiedeberg:
Uranium found here.

7. Prizbram:
The Johanni lode has a 2-5 cm zone in the footwall that has kidney and hazelnut shaped masses of pitchblende.

8. Bain definitely implies that the Jachymov Mines are the best in the area.

SUBJECT: Uranium at Wichstadtl, Czechoslovakia.

TO: Area Engineer, Madison Square Area, Post Office Box 42, Station F, New York, N. Y. Attention: Lt. Col. A. W. Oberbeck

1. The following information has been obtained from an untested source:

a. The radioactive waters near Mladkov (Wichstadtl) Czechoslovakia (50° 8' N., 16° 37' E.) have three times the radioactivity of the Jachymov (Joachimsthal) waters.

b. Uranium deposits are known to be associated with these waters.

c. These deposits were never exploited by the Czechs because competition with Jachymov was not desired.

d. The Germans had planned to exploit these deposits.

e. The Russians are not interested in this area, possibly because it is unknown to them.

2. It is requested that this office be informed if anything further is known on radioactive waters or uranium lodes near Wichstadtl.

RUSSIAN MINING OPERATIONS IN THE GERMAN-CZECH BORDER REGION

By H. S. Lowenhaupt

I. Summary

a. This report is an attempt to coordinate intelligence on Russian uranium mining in the Erzgebirge. It must be clearly understood that not one single absolutely reliable informant has submitted a report on any area mentioned. At best, the report is a compilation of probably reliable to possibly reliable intelligence in which the number of informants agreeing, rather than the personal character of individual informants, is the standard of reliability.

b. All uranium mining and prospecting operations in the Saxony-Czechoslovak Border Region (the Erzgebirge) are carried out under the administration of the Soviet Army headquarters in Potsdam, Germany. Operations at Jachymov were under direct Russian control from August 1945 until February 1946, when administration of Jachymov was turned over to the Czechs under the Secret Fierlinger Agreement. Since late January 1946 Soviet geological reconnaissance parties have been stationed at Karlsbad. With the exception of Jachymov all uranium mines in the Erzgebirge are under direct Russian operational and security control.

c. Sites identified are;

1. Jachymov

Two mines in operation under Czech management and Russian scientific control. Probably 300 miners employed against pre-war total of 200 miners. Concentration plant no longer used, material being sent towards Dresden (Saxony) after preliminary handpicking. Pre-war output 12 tons U_3O_8 annually.

2. Johanngeorgenstadt

16 km. west of Jachymov. 6 mines in operation. 600 to 700 miners employed on three 8-hour shifts with 1200 more expected. Preliminary concentration done in the mines and then this material shipped to Russia. Mining operations started in July 1946 and it is known that the Russians were elated with their finds. Maximum pre-war output was 2.7 tons U_3O_8 in 1905.

3. Oberwiesenthal and Gottesgab

7 km. N.E. of Jachymov. Discovered in October. About 300 miners there starting digging operations and 300 more due. It is known that Russians consider Gottesgab better than Johanngeorgenstadt.

23.40

CR 33,914

TOP SECRET

R

TOP SECRET

4. Schneeberg

35 km. N.W. of Jachymov. Between 1870 and 1907 produced 80 metric tons U_3O_8. Operations apparently started in August 1946. Recruiting of miners still in progress and Russians with families still moving in.

5. Spa Oberschlema

45 km. N.W. of Jachymov. Spa area taken over by Russians in September 1946. By October drilling and shaft sinking in full swing. It is not known what success was had.

6. Schonficht

40 km. S.W. of Jachymov. It is known that uranium occurs here in low concentration. An August report states that uranium was to be mined here.

7. Bad Elster

50 km. west of Jachymov. The Russians took over the Spa in September, apparently as a preliminary step to prospecting by drilling.

8. Bad Brambach

45 km. west of Jachymov. The Russians took over the Spa in September, apparently as a preliminary step to prospecting by drilling.

9. Schonfeld-Schlaggenwald

40 km. S.W. of Jachymov. An unconfirmed report of September 1945 states 2-3 tons of uranium ore shipped to Jachymov per week. No later report received.

d. The distance of all sites from Jachymov has been emphasized because current geological opinion is that the richness of mines falls off with their distance from Jachymov. Thus, as Jachymov produces 12 tons U_3O_8 per year, Johanngeorgenstadt may be expected to produce perhaps 8 tons annually at the same mining rate. Tending to increase output of all mines in the Erzgebirge, except Jachymov, is the apparent increase in the number of miners at any single mine by a factor of from 2 to 5 over the number expected under German practice. This may double expected output if these miners are used efficiently. Another factor to consider is that while the output of a single mine may be quite small, the sum of the outputs of a number of mines may become quite significant. We can thus set a minimum annual production of 15 tons U_3O_8 for the Erzgebirge region, and possibly 30 tons as a maximum.

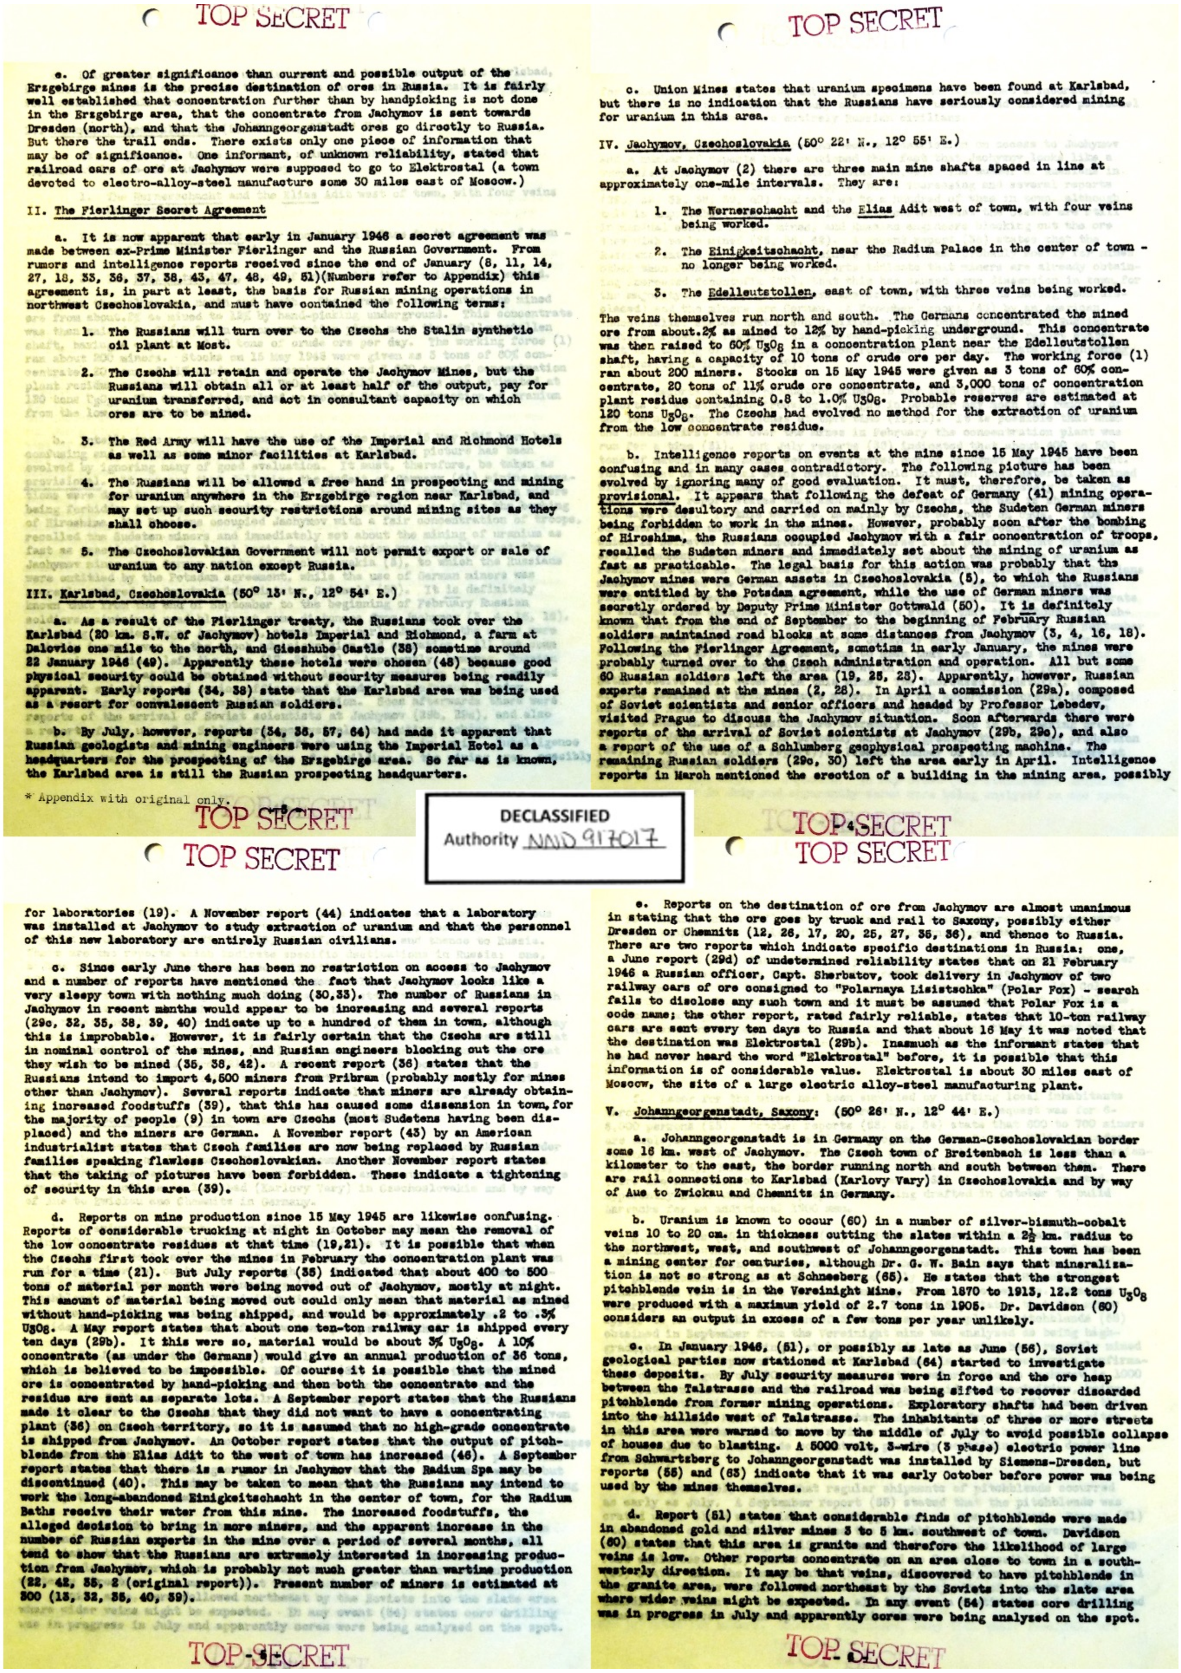
NARA RG 77, Entry UD-22A, Box 163, Folder Czechoslovakia



TOP SECRET

e. Of greater significance than current and possible output of the Erzgebirge mines is the precise destination of ores in Russia. It is fairly well established that concentration further than by handpicking is not done in the Erzgebirge area, that the concentrate from Jachymov is sent towards Dresden (north), and that the Johanngeorgenstadt ores go directly to Russia. But there the trail ends. There exists only one piece of information that may be of significance. One informant, of unknown reliability, stated that railroad cars of ore at Jachymov were supposed to go to Elektrostal (a town devoted to electro-alloy-steel manufacture some 30 miles east of Moscow.)

II. The Fierlinger Secret Agreement

a. It is now apparent that early in January 1946 a secret agreement was made between ex-Prime Minister Fierlinger and the Russian Government. From rumors and intelligence reports received since the end of January (8, 11, 14, 27, 18, 33, 36, 37, 38, 43, 47, 48, 49, 51)(Numbers refer to Appendix) this agreement is, in part at least, the basis for Russian mining operations in northwest Czechoslovakia, and must have contained the following terms:

1. The Russians will turn over to the Czechs the Stalin synthetic oil plant at Most.
2. The Czechs will retain and operate the Jachymov Mines, but the Russians will obtain all or at least half of the output, pay for uranium transferred, and act in consultant capacity on which ores are to be mined.
3. The Red Army will have the use of the Imperial and Richmond Hotels as well as some minor facilities at Karlsbad.
4. The Russians will be allowed a free hand in prospecting and mining for uranium anywhere in the Erzgebirge region near Karlsbad, and may set up such security restrictions around mining sites as they shall choose.
5. The Czechoslovakian Government will not permit export or sale of uranium to any nation except Russia.

III. Karlsbad, Czechoslovakia (50° 13' N., 12° 54' E.)

a. As a result of the Fierlinger treaty, the Russians took over the Karlsbad (20 km. S.W. of Jachymov) hotels Imperial and Richmond, a farm at Dalovice one mile to the north, and Giesshube Castle (38) sometime around 22 January 1946 (49). Apparently these hotels were chosen (48) because good physical security could be obtained without security measures being readily apparent. Early reports (34, 38) state that the Karlsbad area was being used as a resort for convalescent Russian soldiers.

b. By July, however, reports (34, 36, 57, 64) had made it apparent that Russian geologists and mining engineers were using the Imperial Hotel as a headquarters for the prospecting of the Erzgebirge area. So far as is known, the Karlsbad area is still the Russian prospecting headquarters.

* Appendix with original only.

TOP SECRET

TOP SECRET

c. Union Mines states that uranium specimens have been found at Karlsbad, but there is no indication that the Russians have seriously considered mining for uranium in this area.

IV. Jachymov, Czechoslovakia (50° 22' N., 12° 55' E.)

a. At Jachymov (2) there are three main mine shafts spaced in line at approximately one-mile intervals. They are:

1. The Wernerschacht and the Elias Adit west of town, with four veins being worked.
2. The Einigkeitschacht, near the Radium Palace in the center of town - no longer being worked.
3. The Edelleutstollen, east of town, with three veins being worked.

The veins themselves run north and south. The Germans concentrated the mined ore from about .2% as mined to 12% by hand-picking underground. This concentrate was then raised to 60% U_3O_8 in a concentration plant near the Edelleutstollen shaft, having a capacity of 10 tons of crude ore per day. The working force (1) ran about 200 miners. Stocks on 15 May 1945 were given as 3 tons of 60% concentrate, 20 tons of 11% crude ore concentrate, and 3,000 tons of concentration plant residue containing 0.8 to 1.0% U_3O_8. Probable reserves are estimated at 120 tons U_3O_8. The Czechs had evolved no method for the extraction of uranium from the low concentrate residue.

b. Intelligence reports on events at the mine since 15 May 1945 have been confusing and in many cases contradictory. The following picture has been evolved by ignoring many of good evaluation. It must, therefore, be taken as provisional. It appears that following the defeat of Germany (41) mining operations were desultory and carried on mainly by Czechs, the Sudeten German miners being forbidden to work in the mines. However, probably soon after the bombing of Hiroshima, the Russians occupied Jachymov with a fair concentration of troops, recalled the Sudeten miners and immediately set about the mining of uranium as fast as practicable. The legal basis for this action was probably that the Jachymov mines were German assets in Czechoslovakia (5), to which the Russians were entitled by the Potsdam agreement, while the use of German miners was secretly ordered by Deputy Prime Minister Gottwald (50). It is definitely known that from the end of September to the beginning of February Russian soldiers maintained road blocks at some distances from Jachymov (3, 4, 16, 18). Following the Fierlinger Agreement, sometime in early January, the mines were probably turned over to the Czech administration and operation. All but some 60 Russian soldiers left the area (19, 25, 28). Apparently, however, Russian experts remained at the mines (2, 28). In April a commission (29a), composed of Soviet scientists and senior officers and headed by Professor Lebedev, visited Prague to discuss the Jachymov situation. Soon afterwards there were reports of the arrival of Soviet scientists at Jachymov (29b, 29c), and also a report of the use of a Schlumberg geophysical prospecting machine. The remaining Russian soldiers (29c, 30) left the area early in April. Intelligence reports in March mentioned the erection of a building in the mining area, possibly for laboratories (19). A November report (44) indicates that a laboratory was installed at Jachymov to study extraction of uranium and that the personnel of this new laboratory are entirely Russian civilians.

TOP -4- SECRET

DECLASSIFIED
Authority NND 917017

TOP SECRET

c. Since early June there has been no restriction on access to Jachymov and a number of reports have mentioned the fact that Jachymov looks like a very sleepy town with nothing much doing (30,33). The number of Russians in Jachymov in recent months would appear to be increasing and several reports (29c, 32, 35, 38, 39, 40) indicate up to a hundred of them in town, although this is improbable. However, it is fairly certain that the Czechs are still in nominal control of the mines, and Russian engineers blocking out the ore they wish to be mined (35, 38, 42). A recent report (36) states that the Russians intend to import 4,500 miners from Pribram (probably mostly for mines other than Jachymov). Several reports indicate that miners are already obtaining increased foodstuffs (39), that this has caused some dissension in town, for the majority of people (9) in town are Czechs (most Sudetens having been displaced) and the miners are German. A November report (43) by an American industrialist states that Czech families are now being replaced by Russian families speaking flawless Czechoslovakian. Another November report states that the taking of pictures have been forbidden. These indicate a tightening of security in this area (39).

d. Reports on mine production since 15 May 1945 are likewise confusing. Reports of considerable trucking at night in October may mean the removal of the low concentrate residues at that time (19,21). It is possible that when the Czechs first took over the mines in February the concentration plant was run for a time (21). But July reports (35) indicated that about 400 to 500 tons of material per month were being moved out of Jachymov, mostly at night. This amount of material being moved out could only mean that material as mined without hand-picking was being shipped, and would be approximately .2 to .3% U_3O_8. A May report states that about one ten-ton railway car is shipped every ten days (29b). It this were so, material would be about 3% U_3O_8. A 10% concentrate (as under the Germans) would give an annual production of 36 tons, which is believed to be impossible. Of course it is possible that the mined ore is concentrated by hand-picking and then both the concentrate and the residue are sent as separate lots. A September report states that the Russians made it clear to the Czechs that they did not want to have a concentrating plant (36) on Czech territory, so it is assumed that no high-grade concentrate is shipped from Jachymov. An October report states that the output of pitchblende from the Elias Adit to the west of town has increased (46). A September report states that there is a rumor in Jachymov that the Radium Spa may be discontinued (40). This may be taken to mean that the Russians may intend to work the long-abandoned Einigkeitschacht in the center of town, for the Radium Baths receive their water from this mine. The increased foodstuffs, the alleged decision to bring in more miners, and the apparent increase in the number of Russian experts in the mine over a period of several months, all tend to show that the Russians are extremely interested in increasing production from Jachymov, which is probably not much greater than wartime production (22, 42, 35, 2 (original report)). Present number of miners is estimated at 300 (13, 32, 35, 40, 39).

TOP SECRET

TOP SECRET

e. Reports on the destination of ore from Jachymov are almost unanimous in stating that the ore goes by truck and rail to Saxony, possibly either Dresden or Chemnitz (12, 26, 17, 20, 25, 27, 35, 36), and thence to Russia. There are two reports which indicate specific destinations in Russia: one, a June report (29d) of undetermined reliability states that on 21 February 1946 a Russian officer, Capt. Sherbatov, took delivery in Jachymov of two railway cars of ore consigned to "Polarnaya Lisistschka" (Polar Fox) - search fails to disclose any such town and it must be assumed that Polar Fox is a code name; the other report, rated fairly reliable, states that 10-ton railway cars are sent every ten days to Russia and that about 16 May it was noted that the destination was Elektrostal (29b). Inasmuch as the informant states that he had never heard the word "Elektrostal" before, it is possible that this information is of considerable value. Elektrostal is about 30 miles east of Moscow, the site of a large electric alloy-steel manufacturing plant.

V. Johanngeorgenstadt, Saxony: (50° 26' N., 12° 44' E.)

a. Johanngeorgenstadt is in Germany on the German-Czechoslovakian border some 16 km. west of Jachymov. The Czech town of Breitenbach is less than a kilometer to the east, the border running north and south between them. There are rail connections to Karlsbad (Karlovy Vary) in Czechoslovakia and by way of Aue to Zwickau and Chemnitz in Germany.

b. Uranium is known to occur (60) in a number of silver-bismuth-cobalt veins 10 to 20 cm. in thickness cutting the slates within a 2½ km. radius to the northwest, west, and southwest of Johanngeorgenstadt. This town has been a mining center for centuries, although Dr. G. W. Bain says that mineralization is not so strong as at Schneeberg (65). He states that the strongest pitchblende vein is in the Vereinight Mine. From 1870 to 1913, 12.2 tons U_3O_8 were produced with a maximum yield of 2.7 tons in 1905. Dr. Davidson (60) considers an output in excess of a few tons per year unlikely.

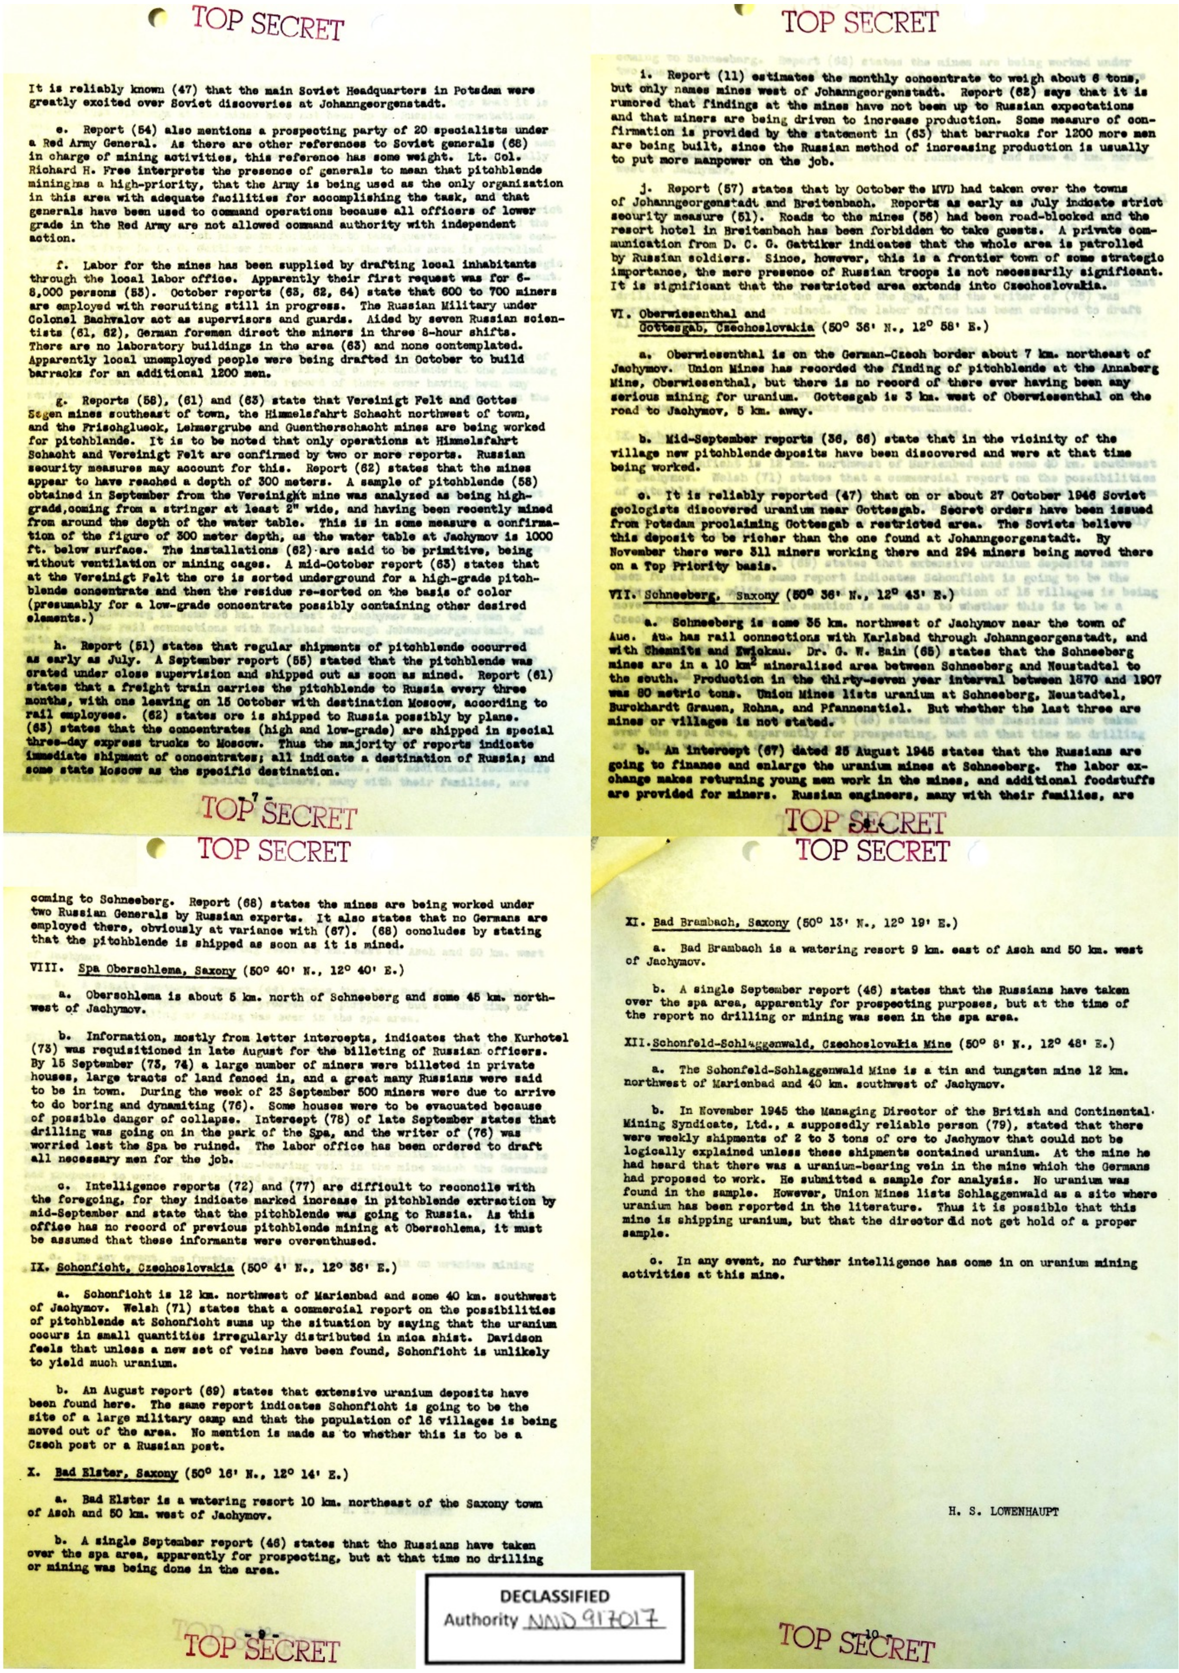
c. In January 1946, (51), or possibly as late as June (56), Soviet geological parties now stationed at Karlsbad (64) started to investigate these deposits. By July security measures were in force and the ore heap between the Talstrasse and the railroad was being sifted to recover discarded pitchblende from former mining operations. Exploratory shafts had been driven into the hillside west of Talstrasse. The inhabitants of three or more streets in this area were warned to move by the middle of July to avoid possible collapse of houses due to blasting. A 5000 volt, 3-wire (3 phase) electric power line from Schwartzberg to Johanngeorgenstadt was installed by Siemens-Dresden, but reports (55) and (63) indicate that it was early October before power was being used by the mines themselves.

d. Report (51) states that considerable finds of pitchblende were made in abandoned gold and silver mines 3 to 5 km. southwest of town. Davidson (60) states that this area is granite and therefore the likelihood of large veins is low. Other reports concentrate on an area close to town in a southwesterly direction. It may be that veins, discovered to have pitchblende in the granite area, were followed northeast by the Soviets into the slate area where wider veins might be expected. In any event (54) states core drilling was in progress in July and apparently cores were being analyzed on the spot.

TOP SECRET

Figure D.90: H. S. Lowenhaupt. 5 December 1946. Russian Mining Operations in the German-Czech Border Region [NARA RG 77, Entry UD-22A, Box 163, Folder Czechoslovakia].

NARA RG 77, Entry UD-22A, Box 163, Folder Czechoslovakia



TOP SECRET

It is reliably known (47) that the main Soviet Headquarters in Potsdam were greatly excited over Soviet discoveries at Johanngeorgenstadt.

e. Report (54) also mentions a prospecting party of 20 specialists under a Red Army General. As there are other references to Soviet generals (68) in charge of mining activities, this reference has some weight. Lt. Col. Richard H. Free interprets the presence of generals to mean that pitchblende mininghas a high-priority, that the Army is being used as the only organization in this area with adequate facilities for accomplishing the task, and that generals have been used to command operations because all officers of lower grade in the Red Army are not allowed command authority with independent action.

f. Labor for the mines has been supplied by drafting local inhabitants through the local labor office. Apparently their first request was for 6-8,000 persons (53). October reports (63, 62, 64) state that 600 to 700 miners are employed with recruiting still in progress. The Russian Military under Colonel Bachvalov act as supervisors and guards. Aided by seven Russian scientists (61, 62), German foremen direct the miners in three 8-hour shifts. There are no laboratory buildings in the area (63) and none contemplated. Apparently local unemployed people were being drafted in October to build barracks for an additional 1200 men.

g. Reports (58), (61) and (63) state that Vereinigt Felt and Gottes Segen mines southeast of town, the Himmelsfahrt Schacht northwest of town, and the Frischglueck, Lehmergrube and Guentherschacht mines are being worked for pitchblende. It is to be noted that only operations at Himmelsfahrt Schacht and Vereinigt Felt are confirmed by two or more reports. Russian security measures may account for this. Report (62) states that the mines appear to have reached a depth of 300 meters. A sample of pitchblende (58) obtained in September from the Vereinight mine was analyzed as being high-gradd,coming from a stringer at least 2" wide, and having been recently mined from around the depth of the water table. This is in some measure a confirmation of the figure of 300 meter depth, as the water table at Jachymov is 1000 ft. below surface. The installations (62) are said to be primitive, being without ventilation or mining cages. A mid-October report (63) states that at the Vereinigt Felt the ore is sorted underground for a high-grade pitchblende concentrate and then the residue re-sorted on the basis of color (presumably for a low-grade concentrate possibly containing other desired elements.)

h. Report (51) states that regular shipments of pitchblende occurred as early as July. A September report (55) stated that the pitchblende was crated under close supervision and shipped out as soon as mined. Report (61) states that a freight train carries the pitchblende to Russia every three months, with one leaving on 15 October with destination Moscow, according to rail employees. (62) states ore is shipped to Russia possibly by plane. (63) states that the concentrates (high and low-grade) are shipped in special three-day express trucks to Moscow. Thus the majority of reports indicate immediate shipment of concentrates; all indicate a destination of Russia; and some state Moscow as the specific destination.

- 7 -

TOP SECRET

TOP SECRET

i. Report (11) estimates the monthly concentrate to weigh about 6 tons, but only names mines west of Johanngeorgenstadt. Report (62) says that it is rumored that findings at the mines have not been up to Russian expectations and that miners are being driven to increase production. Some measure of confirmation is provided by the statement in (63) that barracks for 1200 more men are being built, since the Russian method of increasing production is usually to put more manpower on the job.

j. Report (57) states that by October the MVD had taken over the towns of Johanngeorgenstadt and Breitenbach. Reports as early as July indicate strict security measure (51). Roads to the mines (56) had been road-blocked and the resort hotel in Breitenbach has been forbidden to take guests. A private communication from D. C. G. Gattiker indicates that the whole area is patrolled by Russian soldiers. Since, however, this is a frontier town of some strategic importance, the mere presence of Russian troops is not necessarily significant. It is significant that the restricted area extends into Czechoslovakia.

VI. Oberwiesenthal and
Gottesgab, Czechoslovakia (50° 36' N., 12° 58' E.)

a. Oberwiesenthal is on the German-Czech border about 7 km. northeast of Jachymov. Union Mines has recorded the finding of pitchblende at the Annaberg Mine, Oberwiesenthal, but there is no record of there ever having been any serious mining for uranium. Gottesgab is 3 km. west of Oberwiesenthal on the road to Jachymov, 5 km. away.

b. Mid-September reports (36, 66) state that in the vicinity of the village new pitchblende deposits have been discovered and were at that time being worked.

c. It is reliably reported (47) that on or about 27 October 1946 Soviet geologists discovered uranium near Gottesgab. Secret orders have been issued from Potsdam proclaiming Gottesgab a restricted area. The Soviets believe this deposit to be richer than the one found at Johanngeorgenstadt. By November there were 311 miners working there and 294 miners being moved there on a Top Priority basis.

VII. Schneeberg, Saxony (50° 36' N., 12° 43' E.)

a. Schneeberg is some 35 km. northwest of Jachymov near the town of Aue. Aue has rail connections with Karlsbad through Johanngeorgenstadt, and with Chemnitz and Zwickau. Dr. G. W. Bain (65) states that the Schneeberg mines are in a 10 km^2 mineralized area between Schneeberg and Neustadtel to the south. Production in the thirty-seven year interval between 1870 and 1907 was 80 metric tons. Union Mines lists uranium at Schneeberg, Neustadtel, Burckhardt Grauen, Rohna, and Pfannenstiel. But whether the last three are mines or villages is not stated.

b. An intercept (67) dated 25 August 1945 states that the Russians are going to finance and enlarge the uranium mines at Schneeberg. The labor exchange makes returning young men work in the mines, and additional foodstuffs are provided for miners. Russian engineers, many with their families, are

- 8 -

TOP SECRET

TOP SECRET

coming to Schneeberg. Report (68) states the mines are being worked under two Russian Generals by Russian experts. It also states that no Germans are employed there, obviously at variance with (67). (68) concludes by stating that the pitchblende is shipped as soon as it is mined.

VIII. Spa Oberschlema, Saxony (50° 40' N., 12° 40' E.)

a. Oberschlema is about 5 km. north of Schneeberg and some 45 km. northwest of Jachymov.

b. Information, mostly from letter intercepts, indicates that the Kurhotel (73) was requisitioned in late August for the billeting of Russian officers. By 15 September (73, 74) a large number of miners were billeted in private houses, large tracts of land fenced in, and a great many Russians were said to be in town. During the week of 23 September 500 miners were due to arrive to do boring and dynamiting (76). Some houses were to be evacuated because of possible danger of collapse. Intercept (78) of late September states that drilling was going on in the park of the Spa, and the writer of (76) was worried lest the Spa be ruined. The labor office has been ordered to draft all necessary men for the job.

c. Intelligence reports (72) and (77) are difficult to reconcile with the foregoing, for they indicate marked increase in pitchblende extraction by mid-September and state that the pitchblende was going to Russia. As this office has no record of previous pitchblende mining at Oberschlema, it must be assumed that these informants were overenthused.

IX. Schonficht, Czechoslovakia (50° 4' N., 12° 36' E.)

a. Schonficht is 12 km. northwest of Marienbad and some 40 km. southwest of Jachymov. Welsh (71) states that a commercial report on the possibilities of pitchblende at Schonficht sums up the situation by saying that the uranium occurs in small quantities irregularly distributed in mica shist. Davidson feels that unless a new set of veins have been found, Schonficht is unlikely to yield much uranium.

b. An August report (69) states that extensive uranium deposits have been found here. The same report indicates Schonficht is going to be the site of a large military camp and that the population of 16 villages is being moved out of the area. No mention is made as to whether this is to be a Czech post or a Russian post.

X. Bad Elster, Saxony (50° 16' N., 12° 14' E.)

a. Bad Elster is a watering resort 10 km. northeast of the Saxony town of Asch and 50 km. west of Jachymov.

b. A single September report (46) states that the Russians have taken over the spa area, apparently for prospecting, but at that time no drilling or mining was being done in the area.

- 9 -

TOP SECRET

TOP SECRET

XI. Bad Brambach, Saxony (50° 13' N., 12° 19' E.)

a. Bad Brambach is a watering resort 9 km. east of Asch and 50 km. west of Jachymov.

b. A single September report (46) states that the Russians have taken over the spa area, apparently for prospecting purposes, but at the time of the report no drilling or mining was seen in the spa area.

XII. Schonfeld-Schlaggenwald, Czechoslovakia Mine (50° 8' N., 12° 48' E.)

a. The Schonfeld-Schlaggenwald Mine is a tin and tungsten mine 12 km. northwest of Marienbad and 40 km. southwest of Jachymov.

b. In November 1945 the Managing Director of the British and Continental Mining Syndicate, Ltd., a supposedly reliable person (79), stated that there were weekly shipments of 2 to 3 tons of ore to Jachymov that could not be logically explained unless these shipments contained uranium. At the mine he had heard that there was a uranium-bearing vein in the mine which the Germans had proposed to work. He submitted a sample for analysis. No uranium was found in the sample. However, Union Mines lists Schlaggenwald as a site where uranium has been reported in the literature. Thus it is possible that this mine is shipping uranium, but that the director did not get hold of a proper sample.

c. In any event, no further intelligence has come in on uranium mining activities at this mine.

MEMO TO FILE

FROM: H. S. Lowenhaupt

SUBJ: Tin and Tungsten Mining in the Erzgebirge.

1. Altenberg and Zinnwald (50° 46' N., 13° 47' E.)

According to a U. S. report, cassiterite, wolframite, and pure bismuth occur in strata surrounding a granite dome. These two mines were owned by the Zwitterstocks Corporation and the Zinnwalder Mining Company. Both mines were worked regularly up to 1938. Presumably about 1938 a central ore dressing plant was set up in Altenberg and a crushing plant for further benefication was set up in Freiberg* (50° 55' N., 13° 21' E.) some 20 km. northeast of Chemnitz. This plant had a daily capacity of 300 tons.

2. Ehrenfriesdendorf (50° 39' N., 12° 58' E.)

The Ehrenfriedersdorfer Vereinigt Felt Fundgrube, 24 Km. east northeast of Schneeberg, consisting of 6 ranges of veins of total length of 2 km. and locally containing molybdenum as well as cassiterite and wolframite, may have been worked by the Germans.

U.K. Int. Summary #42 13-20 Dec/46

3. Tannenbergstal (50° 26' N., 12° 27' E.)

The Tannenberg mine with tin bearing "greisen" may have been worked. (20 km. southwest of Schneeberg and 19 km. west of Johanngeorgenstadt.) Mine is in giant quartz vein in the Aue granite.

4. Gottesburg* (50° 25' N., 12° 28' E.)

The Gottesberg-Weidmannsheil-Vereinigt Felt mines may have been worked for tungsten. Gottesburg is 1½ km. southeast of Tannenbergstal.

5. Zschorlau* (50° 34' N., 12° 39' E.)

The Zschorlauer Bergsegen, some 3 km. south of Schneeberg may have been worked for tungsten.

6. Pobershau* (50° 38' N., 13° 11' E.)

Near Marienberg. There were no regular operations undertakn by the Germans at the tungsten veins here.

7. Eibenstock* (50° 30' N., 12° 36' E.)

At Donitzgrund near Eibenstock, 12 km. northwest of Johanngeorgenstadt

and 11 km. south of Schneeberg there is tungsten which was not worked by the Germans.

8. Schmiedeberg* (50° 35' N., 13° 9' E.)

Sadisdorf near Schmiedeberg contains a tungsten vein which was not worked by the Germans.

9. Olsnitz in Vogtland near Lauterbach* (not found) has tungsten which was not regularly worked by the Germans.

U.K. Int. Summary #42 13-20 Dec/46

10. A wolframite sample has recently been received reputedly from Zschorlau.

11. From the evidence in (3) and (4) above, it must be recognized that the Russians may be mining only tungsten in localities at which uranium mining has been reported.

11 May 1945

SUBJECT: 1. Medical Publications Given by Dr. Georg Mattig, 9 May 1945.
2. Interview with Prof. K. Bonnhoefer of the University of Leipzig, 10 May 1945.
3. Interview with Dr. W. Büchler, Director of the Büchler Chemische Fabrik of Braunschweig, 11 May 1945.
4. Interview with Dr. Eisenberg, Braunschweig, 11 May 1945.

TO : Scientific Chief, Alsos Mission,
APO 887, U. S. Army.

1. MEDICAL PUBLICATIONS GIVEN BY DR. GEORG MATTIG, 9 MAY 1945.

Dr. Mattig having sent word that a number of recent medical publications were available in the library of the Hygienisches Institut of the University of Göttingen, selected a number of recent Army Medical Publications together with Atlas's showing the spread of diseases, and gave them to the writer. They appeared to be of no interest to Alsos, but will be forwarded to the Paris office, where Captain Cromartie may care to examine them and turn them over to the medical authorities to whom they may be of interest. Dr. Mattig, who normally engages in medical research in Frankfurt, is confined to Göttingen as a prisoner of war.

2. INTERVIEW WITH PROF. K. BONNHOEFER OF THE UNIVERSITY OF LEIPZIG, 10 MAY 1945.

A visit to Prof. K. Bonnhoefer, Director of the Physicochemical Institute of the University of Leipzig, was made at his summer place in Friedrichsbrunn über Gernrode, Ost-Harz. As was anticipated, the visit yielded no information of real importance but threw a certain amount of light upon matters of personnel interest. Prof. Bonnhoefer was greatly aged and worn. Two of his brothers had been condemmed to death for participation in the 20 July revolution of last year, and he did not know whether the sentence had been carried out. Under the circumstances, he is strongly anti-Nazi. Although he has been working on war projects,

he claimed that they were of no real military importance. He followed the line taken by a number of other German scientists in saying that the war had been made to serve science rather than science the war. He played down the importance of heavy water, and expressed the view that it would be ten years before any practical use could be made of it in the atomic energy problem. He claimed to be very much on the outside in this problem and said that Harteck and Clusius were in the inner circle with Gerlach, Heisenberg and Bothe. He said that Harteck, Hahn, Hund and Jost were among the good scientists who were very definitely not Nazis. He had had under consideration for some months, a full time position with Osram.

3. INTERVIEW WITH DR. W. BÜCHLER, DIRECTOR OF THE BÜCHLER CHEMISCHE FABRIK OF BRAUNSCHWEIG, 11 MAY 1945.

Dr. W. Büchler, Director of the Büchler Chemischen Fabrik, Frankfurterstr. 294, Braunschweig, was interviewed on 11 May 1945, in the one small building remaining of his factory at that address. The principal function of his company at the present time is producing quinine under the supervision of Allied Military Government. One of the company's normal lines of work is the extraction of radium from ore obtained from their own mine in Joachimstal, a mine rented from the government. Of recently produced radium, approximately one (1) gram was shipped to Strassburg, while one (1) gram remained with the company. Before the war, the major portion of the uranium oxide produced was donverted to a yellow pigment for use in paint manufacture. With the coming of the war, the government forbade that use of uramium and required that it be converted to ammonium uranate, which was shipped to the Roges Company in Berlin. Roges may have shipped it in turn to Auer, but Büchler is not certain of the destination of the material after it was sent to Roges. He volunteered the information that it was converted into metallic uramium for use in atom smashing ("Atomzertrümmerung"). Büchler estimated that the company had on hand about four (4) tons of ammonium uranate, one (1) to two (2) tons of sodium uranate, and three (3) tons of raw material containing about 55% uranium oxide. The records of the company are at Boerssum. The radium produced by the company was used for the filling of small tubes, for cancer treatment, and was handled by Allgemeine Radium A.G., Berlin, a small company "bought" from Katanga, the Belgium concern. A certain amount of radioactive material was shipped to various watch making companies in the Schwarzwald.

When asked about radium supplies in Germany, Dr. Büchler said that considerable quantities were available in hospitals throughout Germany, and that a quantity of about thirty (30) grams acquired by the Reichsanstalt from Belgium was hidden in a cave which he thought to be in the Thüringerwald. He said that the Belgians were aware of

- 2 -

SECRET

of this. This would appear to be the material of which we have heard from other sources.

4. INTERVIEW WITH DR. EISENBERG, BRAUNSCHWEIG.

Dr. Eisenberg of Gausstr. 13, Braunschweig, was interviewed with his wife at Nordstr. 46, Braunschweig, where he is staying with his sister. He said that he had developed an acoustic fuse which had received a successful try-out. It was designed for a bomb to be dropped from a plane on enemy bombers. In the single try-out, it was dropped from a height of about a thousand meters above another plane and exploded at a distance of about 15 meters from the second plane. As his institute was destroyed by bombing, and as materials could not be obtained for further work, the fuse did not go into production. The reports dealing with the work are at Eisenberg's summer place at Auerhahn bei Goslar. Dr. Kuiper and the writer expect to visit Auerhahn and obtain these reports within the next 24 hours and will forward them. Dr. Heinz Stappenbeck, Braunschweig-Lehndorf, Saarstr. 7, was also engaged on the work.

CHARLES P. SMYTH,
Expert Consultant.

MEMORANDUM:

TO : George R. Eckman
Lt. Colonel, MI
Deputy Chief of Mission

1. Will you please transmit to Major Calvert the following TA information:

a. The interrogation of Dr. Ihwe of the Auergesellschaft has yielded the following results:

(1) As mentioned in a previous communication, Dr. Riehl who did the actual work on metal production has gone to Moscow. Riehl was the one who had direct contact with Heisenberg and others.

(2) The uranium in Germany was almost exclusively obtained from Belgian stocks. It was Director van Stappen who informed Ihwe where the stocks could be found. Ihwe was not connected with the search for uranium in France. That was probably taken care of by "Roges" as reported in early Alsos reports. The present whereabouts of German uranium stocks were not known to Ihwe actually. Ihwe claims that about 30 tons, probably oxide, were taken to Russia from the Auer Company. Another 20 tons belonging to the army were stored in Landsberg and were removed to Russia. An unknown large quantity belonging to "Roges" (Dr. Faust) was stored near Stassfurt. Another 100 tons were stored in a chemical factory at Goldbeck near Lübeck. The supply was still there in January 1945. About 20 tons are supposed to be stored in a quinine factory at Buchler near Brunswick. Dr. Smyth who visited this place several months ago reported that the director had informed him of the presence of a few tons of this ore. Finally, about 60 tons of thorium compounds were removed from STR in France. The estimated yield of Joachimsthal, according to Ihwe, was about 3 grams of radium per year, or about 30 tons of uranium. In addition, as reported before, Riehl's secretary, Miss Blobel, told us that a small amount of metallic uranium had been removed by the Russians from Oranienburg.

Figure D.94: Samuel Goudsmit to George R. Eckman. 3 September 1945 [NARA RG GOUDS, Entry UD-7420, Box 3, Folder "Historian's Office Inventory Control Job Goudsmit Box 4 Folder 6"]. "About 20 tons are supposed to be stored in a quinine factory at Buchler near Brunswick."

Sabine Elisabeth Gollmann. 1994. *Die Radium- und Uranabteilung der Treibacher Chemischen Werke: Unter Berücksichtigung des deutschen Atombombenprojektes während des Zweiten Weltkrieges.* Ph.D. thesis. Graz: University of Graz. p. 128.

Der Anschluß an das Dritte Reich wurde seitens der Treibacher Geschäftsleitung sehr positiv aufgenommen, da man sich eine Verbesserung der wirtschaftlichen Lage erhoffte. 1939 wurden die TCW Mitglied der St. Joachimsthaler Bergbaugesellschaft m. b. H. und bezogen dadurch den größten Teil der Rohstoffe aus St. Joachimsthal (Böhmen). Das Kärntner Unternehmen erhielt von dieser wichtigen Erzlagerstätte auch Uranpechblende und es wurde 1940 innerhalb der Radiumabteilung ein eigener Bereich für Uran eingerichtet. Ein Gesellschaftspartner der JOBERG war die Auergesellschaft in Berlin, welche eng mit dem deutschen Atombombenprojekt im Zweiten Weltkrieg verknüpft war. Die Berliner Firma ließ während des Krieges ihre Erzkonzentrate aus St. Joachimsthal in Treibach umarbeiten. Daher sind Beziehungen der TCW, wenn auch über Dritte, zum Kernenergieprojekt sehr wahrscheinlich. Mehrere Indizien sprechen dafür, absolute Beweise sind allerdings nicht mehr auffindbar. Wichtig ist sicherlich, daß ab Anfang der vierziger Jahre radioaktive Substanzen nur mehr für Rüstungszwecke verwendet werden durften. So wurde Radium ab 1942 nur mehr für die Leuchtfarbenherstellung innerhalb der Rüstungsindustrie genutzt.

Im Mai 1945 wurde Kärnten von englischen Truppen besetzt. Die Treibacher Werke wurden als Deutsches Eigentum eingestuft, da ein beträchtlicher Aktienanteil im Besitz eines deutschen Unternehmens gewesen ist. Das gesamte Mesothor und Radiothor wurde von den Engländer beschlagnahmt und später entschädigt. Auf Grund des dadurch entstandenen Rohstoffmangels wurde die Radium- und Uranabteilung 1946 stillgelegt.
